EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. X. NEW YORK, JULY 2, 1890. No. 118

Notwithstanding the losses necessarily incurred by the use of an accumulator, the latter is an economy in private installations, and no doubt eventually for public supply.—Sir D. Salomons.

WATER POWER ELECTRIC MOTOR SERVICE.

OUR recent article on some of the results obtained by Mr. G. A. Redman, at Rochester, in the introduction of the electric motor, has, we are glad to find, awakened very general interest. It will be remembered that the Rochester Brush Electric Light Company utilizes the lower falls of the Genesee river. It has built up a large lighting business and has now turned its attention to power with such success that it has already over 500 motors in active service. We mentioned as one example of the manner in which the business had been worked up that the company was furnishing power to no fewer than 108 tailor shops.

Several inquiries have been addressed to us on the subject, and the question that seems to arouse most interest is that of rates. We are glad to be able to give the information required, and in doing so would point out that the ruling idea has been to build up a good business at a steady income. Another point deserving comment is that Mr. Redman has attained his results on arc circuits which have not always, so far, been the best to work upon, owing to obvious difficulties with many of the motors hitherto obtainable. The rate charged at Rochester for one-eighth h. p. for sewing machines is $18 per annum. A special rate of $15 for a one-eighth is made for fan service, for the season, from June 1 to October 1. In view of the fact that such fan motors are practically kept at it without cessation during that season, the charge is very reasonable. At any rate it is cheerfully paid, and in cases of sickness the motor has been such an inestimable boon that the customers were willing to pay any price for it. For a one-half h. p. motor the fan service rate is $35 for the season; and $50 for one h. p. For the half h. p. on ordinary work, the yearly rate is $48, and for the one h. p., $72. In other words, for 25 cents a day, a small manufacturer, printer, tailor, or storekeeper has one h. p. always at his command without bother or thought or attention on his part; and the amount of work that a steady one h. p. will do is not fully realized. It is this easy command of cheap power in small units that, in our opinion, is destined to bring about some notable industrial changes in due time.

Coming to the larger sizes, we find that Mr. Redman gets $120 per annum for two h. p.; $250 for five; $300 for six; $400 for eight; $475 for ten and $700 for fifteen. The last quotation brings the rate down to only a little over $46 per horse-power per year. What better can a manufacturer using 15 h. p. ask than such a rate, which gives him the fullest power he is paying for, by the mere closing of a switch, and upon the instant?

We hope to see the Rochester results duplicated elsewhere; in fact we know of several instances where the utilization of the water power in this manner will be among the most striking advances of the time in this field. It is no longer necessary to huddle together down in the unhealthy valley, close to the turbid stream, on ground that costs as much as the mills built upon it. The power developed by the water can be delivered miles away in the smallest as well as the largest quantities, under conditions favorable to the well-being of the employés and to the higher perfection of the factory product.

ELECTRIC RAILWAY WORK ABROAD.

ONE of the leading electrical engineers in England, who has done splendid pioneer technical work in electrical railroading, writes us in a grimly humorous way about the conditions that have to be contended with there. Overhead conductors roads would not be allowed, he says, though for the life of us we cannot see why. He goes on, however, as follows :—

"Even if accumulators were dirt cheap and almost everlasting, we must have acts of Parliament—a separate one for each road—which are costly, and take time to get. Then comes the question, who is to obtain those Acts? The tramway company, or the contractors for the plant?"

Fancy going to Congress, or even to a State Legislature, every time we wanted to build an electric road! That would be too much even for American patience and grit.

"After the Parliamentary Act come the vestries, and local boards who are, to say the least of it, mostly ignorant humbugs, existing principally for the purpose of retarding progress. These corporations cling to all the traditions of of centuries ago. But the worst of all are the tramway companies themselves. Of these there are about 70 in these Islands. Sixty of these are paupers, don't pay a decent dividend, haven't a penny to spare, dare not increase capital without more Acts of Parliament, ask you to find everything, and then perhaps allow you to make a handsome profit for their stockholders without any thanks. I could write a history of many pages—sad, pathetic and comical,—on this subject and on my interviews during the past 7 or 8 years with M. P.'s, tramway directors and managers, mayors, vestrymen, Board of Trade officials and gangs of other individuals. You Americans are a different

sort of humanity. I am longing for the next opportunity to cross the Atlantic and shake you all by the hands—good, honest, appreciative hands."

All one can reply to such an outburst as this, is:—"Come over and join us!" It is not all an easy victory here, and we still have street railway men who in convention ridicule electricity and prefer to discuss the disposition of manure; but still we do see some return for the work done, and the rapidity of growth in the field of electric locomotion taxes one to keep pace with it.

Even our negotiable boards of aldermen would rather vote for electricity than against it; and if they oppose it they have something more tangible as an argument governing their action than mere blind and stupid prejudice.

It seems to us, however, that the change of front that our correspondent longs for and has worked for in England, is not very far away; and, if it be, the Continent is certainly ripe for the new departure. Our information is such as to lead us to believe that this year will see great activity in Europe in electric railroading, and that Americans will take a share in it.

TRANSFORMER PHENOMENA.

The appearance of the alternating current transformer in the field of practical electricity was naturally accompanied by searching inquiries as to the exact phenomena manifested in its operation and their effects on its regulating qualities, which of course involve its efficiency. It was soon determined that that early bugbear of the continuous current armature, Foucault currents, required the adoption of special precautions in the direction of increased lamination of the iron. But besides this, another phenomenon, before but dimly recognized, acquired prominence at once, and an importance second only to that of the Foucault currents. It is now known as hysteresis. While the precautions necessary to avoid losses by Foucault currents are easily applied, those demanded for the suppression of losses by hysteresis are by no means as simple, depending as they do upon the quality of the iron, and being independent largely of its state of sub-division. Again, as experience soon showed, the losses from hysteresis depended also to a very great extent upon the degree of magnetization at which the iron was worked, the losses increasing with the increased density of lines of force per unit area.

Study in this work is fortunately still being carried on. The results of recent experiments continue to throw more light upon the transformer, and, we are glad to note, they indicate that improvement in its manufacture is going on steadily. This is well demonstrated in the paper read by Messrs. Humphrey and Powell before the American Institute of Electrical Engineers, which we print elsewhere. While the initial experiments in this direction made at Cornell were carried out on a 10-light transformer, the later ones were effected with a 40-light transformer of the same general design, but of more recent manufacture. The result shows that whereas the 10-light transformer had an efficiency of 86 per cent. at normal load, and an "all-day efficiency" of about 40 per cent., the 40-light transformer reached an efficiency of 96.2 per cent. at normal load, and the high "all-day efficiency" of 90 per cent.

This remarkable result can evidently only be attributed to the improvement in the grade of the iron employed, although the larger capacity of the transformer may have contributed to some extent to the increased efficiency, as is usually the case in electro-magnetic machinery. It is curious to note, however, that while in the 10-light transformer paper insulation was used between the laminæ of iron to suppress the Foucault currents, the insulating skin of the laminæ alone was found sufficient to effect the desired result in the 40-light transformer. The relations which the primary and secondary currents and E. M. F.'s bear to one another under different loads and conditions are very graphically brought out in the paper referred to, and suggest the lines on which further improvement may be looked for.

Taking up the subject of transformers from another standpoint, Prof. Harris J. Ryan, at the same meeting of the Institute, discussed phenomena which have created considerable interest in many quarters. Our readers will remember that some time ago Mr. E. G. Acheson, of Pittsburg, announced the discovery by him that the output of the transformer could be considerably augmented by the heating of the core. The most natural explanation of this was to ascribe it to the increase in the permeability of the iron at the increased temperature. But while this is true to some extent, Prof. Ryan shows that the principal phenomenon to be taken into account here is that of the Foucault currents; and he further shows that the heating of the core increases the electrical resistance to such an extent that these currents are almost entirely suppressed. Prof. Ryan also points out the probable reason why converters of the special form illustrated in his paper are subject to considerable variation in the ratio of the primary to the secondary E. M. F., namely, as being due to the fact that the induction through the air space is a variable quantity, depending upon the load. We hope that these experiments will be carried out at greater length, until the exact useful limitations of the "heated core" converter are determined.

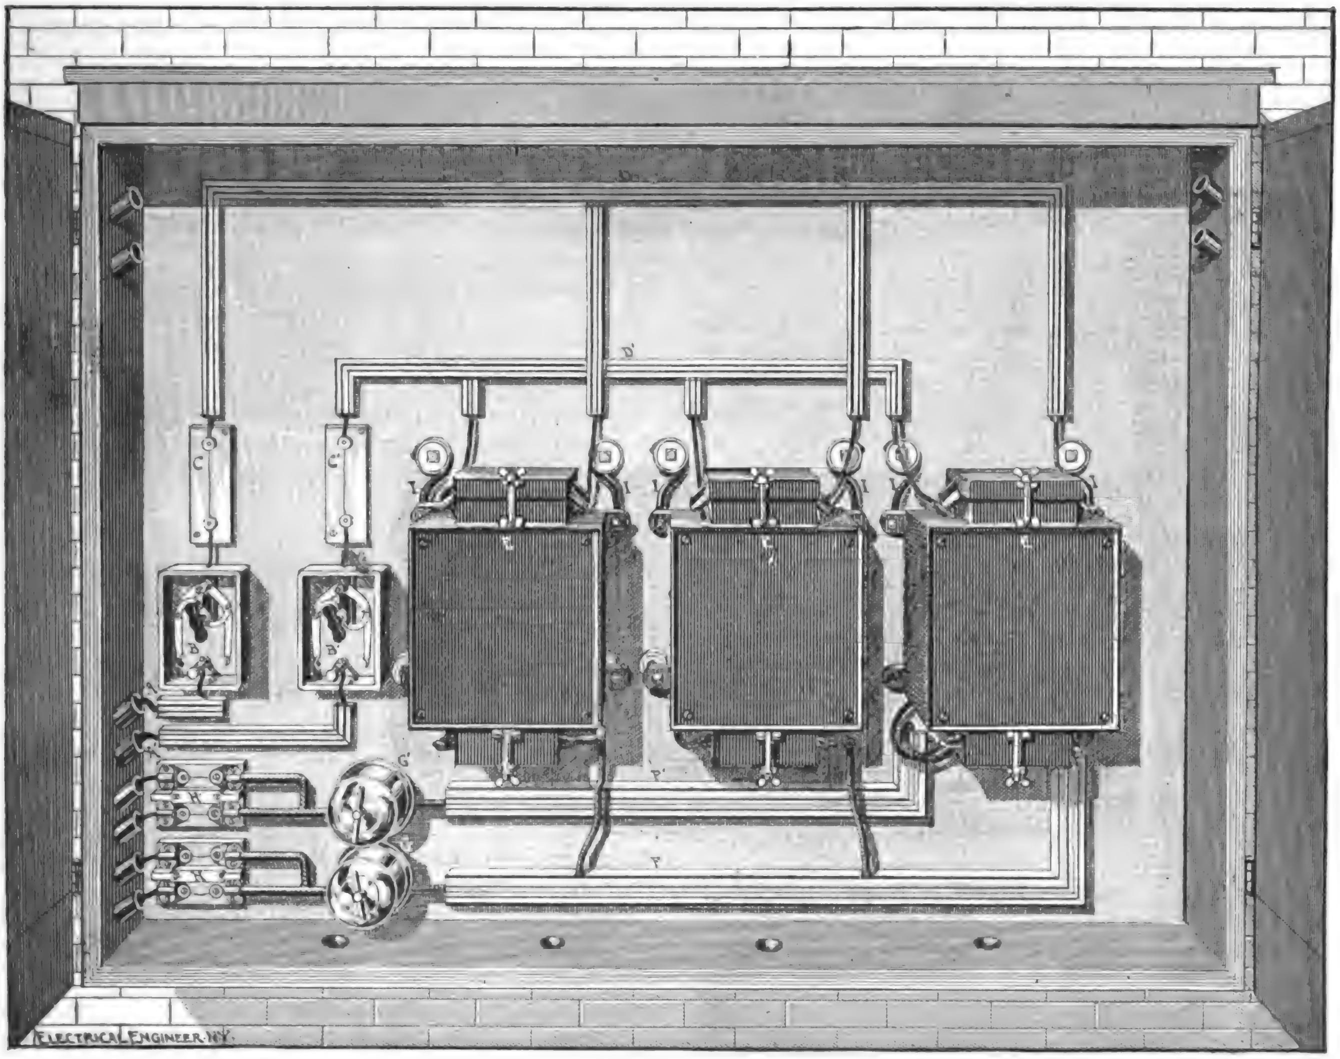
Converter Cabinets.

The steady improvement that is seen on all sides in the insulation of lines and apparatus for light and power is a sure sign that the industry has passed beyond the stage when it was supposed that anything would do. The real fact is that to-day the standard is higher in electric lighting, for the nature of the work, than in telegraphy and fully as high as in telephony. The old idea that good insulation was too costly is scouted, after having done mischief enough to blast any industry not possessed of the inherent vitality and superiority exhibited by electric lighting. Cheapness does not necessarily mean ruin, but where it is the only end sought, disaster and failure are inevitable. It is, of course, in cities where the conditions are so exacting that the advances are first seen, and every-one must admit how great those advances are, especially in the work for the introduction of the alternating incandescent light. We illustrate this week an arrangement worked out by Mr. John A. Seely, and now being adopted by the Harlem Lighting Company, of this city, for the housing of converters and accessory apparatus. The methods adopted to insure safety in every respect must, if carried out generally, remove the last chance for an accident. The spirit that prompts to work of this character is commendable, and we hope to see a good deal done in this direction.

THE NEW CONVERTER CABINET OF THE COMPLETE ELECTRIC CONSTRUCTION CO.

In many towns of a limited number of inhabitants the practice is frequently followed of attaching the converters used in the alternating current system of distribution to poles, and running the distributing wires to the premises where the light is being used. While this method presents no serious obstacle in such cases, it is evidently unsuited to application in a large city and other methods must be employed. This is more particularly the case where the distribution is an underground one, and the wires are led into the premises by cables. The converters being thus in close proximity to the dwellings, it becomes necessary to take due precaution to prevent accidents of all kinds, and which is lined on the inside with asbestos cloth, dressed with a coating of the new insulating compound, "Seeline," and covered on the top with canvas, thus making the entire supporting structure fire-proof and water-tight.

The primary wires from the high tension mains are brought in through the inlets A A¹ and pass into the primary switches B B¹ designed by Mr. Barberie, and the construction of which will be described presently. Immediately beyond the switches are the fusible cut-outs C C¹ which are placed vertically, and from there the current passes by the leads D D¹ to the converters E E E, also, as usual, provided with the primary cut-outs at the tops of the box. The secondary currents after passing through the fusible cut-outs at the bottom of the converters, pass



Converter Cabinet for Buildings in Cities.

in carrying out this idea the work which is now being installed in this city in connection with the Harlem Lighting Co. is worthy of attention, as embodying undoubtedly ingenious, correct and well approved methods of construction, and which must place this system of distribution practically beyond the danger of an accident.

The entire interior wiring for the Harlem Lighting Co. is carried out by the Complete Electric Construction Co. of this city, of which Mr. John A. Seely is the electrician and general manager. The means by which safety is insured are obtained by enclosing the entire complement of converters, switches and cut-outs in a box or cabinet which is shown in the accompanying illustration. Such a box is placed in the vault of each building to be lighted, outside of the building line. The box is constructed of wood, into the leads F F¹ and thence into the secondary switches G G¹ which control the house service, and thence into the cut-outs H H¹ to the lamp circuits. The house service here shown is arranged to provide for two circuits, the conductors, it will be seen, being split after leaving the switches G G¹, each circuit passing through its individual cut-out.

The primary switches B B¹, it will be noted, are placed beyond the fusible cut-outs so that a fuse can be replaced at any time without danger by opening the switches. These switches, as will be seen, are of peculiar construction, the object being to secure an absolute break of considerable length, so that on opening them the underground line can be tested with absolute certainty. The switch has a pair of arms which are controlled by a switch

handle and when brought together clasp a knob to which the primary circuits are connected. Our engraving shows the switches open, the position in which the test would be made. These switches, as well as all others within the box, are mounted on indestructible insulating bases, and the leads run in moldings wherever possible. The converters it will be noticed are suspended from insulators by means of iron hooks I I.

To provide for a thorough ventilation of the box, it is perforated with air holes at the bottom, and similar vents at the top of the box and the sides permit of a free circulation of air.

With the thorough construction embodied in the box described above, it is evident that every precaution has been taken which practice and experience have dictated, and we hope to see all the work of this nature carried out in an equally substantial manner.

THE EDISON SYSTEM OF UNDERGROUND ELECTRIC TUBES.

It is now nearly ten years ago that the first Edison underground tubing was laid in the streets of New York, and what was then a bold experiment rapidly developed into regular practice, so that to-day we find hundreds of miles of the Edison tubing in successful practical operation. Although the lines originally laid down by Mr. Edison have not been departed from in any essential manner, the practice of the art has gradually advanced and effected changes in detail which have brought the system to its present state of perfection. With the object, therefore, of affording our readers information as to the latest improvements and methods of installing the system, we give below a description of the same as it exists to-day and for which we are indebted to the courtesy of the Edison General Electric Co.

An electric tube consists of one or more conductors contained in and insulated from an iron pipe. In the three-wire system which we propose to describe, three copper rods are placed in each pipe. The system is a sectional one, and each tube is as complete when it leaves the factory as is a rail from a rolling mill. Like a rail it needs only to be joined to other similar units to become part of a continuous line.

In the three-wire system of distribution the conductors, whether overhead or underground, are divided into two classes, viz., feeders which run from the dynamos to centres of distribution and mains which radiate from centres of distribution and loop the ends of the feeders together, constituting the second class. All taps to supply customers with electric current are taken from the mains. Electric tubes are accordingly divided into feeders and mains. A main electric tube, or, more briefly, a main, has three insulated copper conductors of equal size. A feeder electric tube, or feeder, has two principal conductors and one smaller conductor to serve as a neutral wire. A feeder also has three insulated cables of seven No. 19 B. W. G. wires each. These small cables form independent circuits from the station to the point of distribution, and enable one to read in the station the electrical pressure at the outside end of the feeder. Hence these lines are called pressure wires.

The system of numbering electric tubes is based on the Edison wire gauge. The size of any tube is the number of thousand circular mils in its positive or negative conductor. Thus a rod one-half inch in diameter has 250,000 circular mils area, and a tube having three such rods would be a No. 250 main.

Four sizes of pipe are used in the standard Edison tubes, and the range of sizes is given below. All pipe diameters are nominal inside diameters.

80,000	circular mils to	120,000	circular mils in	1½" pipe
150,000	" " "	300,000	" " "	2" "
350,000	" " "	600,000	" " "	2½" "
700,000	" " "	1,000,000	" " "	3" "

The copper rods are all 20 feet 4 inches long, and project from each end of the pipe. All 1½" and 2" pipes are cut 20 feet long, allowing 2" projection of copper; 2½" pipes are cut 19 feet 10 inches long, giving 3" projection; 3" pipes are cut 19' 9" long, giving 3½" projection of rod. The rods are drawn to exact gauge of the finest and purest lake copper, and have a conductivity in excess of 98 per cent. The pipes are the best grade of lap welded steam pipe free from imperfections and of full weight.

Fig. 1 shows sections of standard sizes of mains and feeders. Two additional small mains, No. 67 and No. 41 are made in 1¼" pipe for service work only.

In making up a tube the ends of the copper rods are first chamfered and tinned and the pipe thoroughly cleaned on the inside. Each rod is wound separately with a prepared rope, and three rods so wound are made into a triangular bundle and wound with a fourth rope. This bundle of rods bound with rope is slid into the pipe, which is afterwards filled with insulating compound. A special process insures an entire absence of air bubbles, and the ends of the pipe are closed with rubber plugs. The tube is now tested by means of a delicate Thomson reflecting galvanometer. The tube, after testing, is painted to preserve the iron from rust, and is ready for shipment.

In order to complete the system there is required a means of joining the ends of the conductors in consecutive tubes, and of protecting and insulating such a joint when made.

Fig. 2 shows a joint between two main tubes partially completed. The side on the neutral joint is in position ready to solder. The top coupling joint is being slid into place, while the bottom coppers are untouched.

In Fig. 3 is shown a feeder joint partially completed. In feeder tube joints, after the copper rods forming the main conductors are joined, the pressure wires, referred to in the definition of a feeder, are connected by soldering a wrapped splice, and then taping over the splice with insulating tape. The coupling joint which connects the rods is made of pieces of flexible cable with sockets cast on each end. These sockets are drilled to fit easily over the rods which the joint is to connect. Fig. 4 shows a number of sizes of coupling joints in different views. Shorter and longer joints are made for use in turning corners, and are called elbow joints. Various combinations of elbow joints for different angles are given below. A branch or service joint is for use where a tap is taken from a main line to supply a customer. They differ from other joints in having a socket on one end only, and a round pin-like projection or teat at the other end of the piece of cable. This teat fits into the holes noticed in the sides of the sockets of coupling joints, Fig. 4.

Fig. 5 shows the branch joints and link used on all service connections up to and including 120,000 circular mils area.

Having described the joints for straight lines, bends and branches, we come now to their protection and insulation. For protecting straight work, an iron box made in two halves and called a coupling box, is used.

In Fig. 6 is shown a ball clamp which is bolted around the tube as in Figs. 2 and 3. These clamps are split collars, and grip the tube firmly. The sockets at each end of the coupling box form with the ball of the clamp a ball and socket joint. Ball clamps are made in three styles for use with 3", 2½" and 2" coupling boxes. The 2½" style is made in three sizes for use with 2½", 2", or 1½" pipe. The 2" style is made in two sizes for 2" and for 1½" pipe. A clamp for use on a pipe whose inside diameter is less than that of the largest tube used in the coupling box is called a reducing clamp. Thus a 1½" pipe, when used with a 2½" coupling box, takes a 2½" x 1½" reducing ball clamp.

A 2½" coupling box is shown in Fig. 7. The 3" and 2" coupling boxes do not differ, except as to size. The two halves of the box are bolted together by bolts through the flange. In the top half is a round hole closed by a cast iron cap. Through this hole the box is filled with hot in-

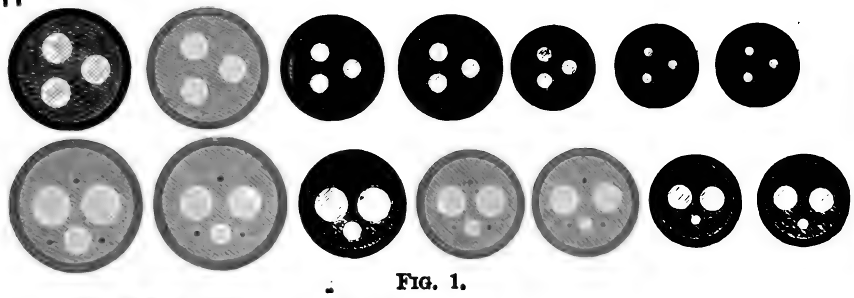


FIG. 1.

FIG. 6.

FIG. 7.

THE EDISON SYSTEM OF UNDERGROUND ELECTRIC TUBES.

sulating compound, which surrounds and insulates the copper rods, the joints, and the tube ends. This compound does not grow brittle on cooling or with age, but remains plastic even at temperatures below the freezing point. An elbow box, 2½″, 90°, is shown partially inclosing an elbow joint between two main tubes in Fig. 8. The 55° and 20° elbow boxes are similar in general design. All elbow boxes allow a range of 18° on either side of their mean position. Thus any angle between 37° and 73° may be made with a 55° elbow box. The 3″ elbows differ from the 2½″ only in being larger. All elbow boxes take special clamps called cup clamps. These clamps have spherical surfaces like ball clamps, but are designed to give a greater range of movement to the ball and socket joint formed with the elbow box. The clamps for the 3″ elbow boxes are similar to the 2½ inch cup clamp shown in Fig. 8. All boxes, whether coupling or elbow, have a round hole in the top half through which they are filled with compound. This hole is closed by a round iron cap which is locked securely in position by turning it through ¼ of a revolution. This cap, shown in Fig. 9, makes a dirt-tight but not air-tight joint, and is called a ventilator top.

Having disposed of the main line, we come to the branches leading to the customer's premises, or, as they are commonly called, the services. These are short lengths of tube which tap the main line by means of a three-way box called a tee box (see Figs. 10 and 11). These boxes are made in two styles, 2″ tee and 2½″ tee, which differ from the 2″ coupling and the 2½″ coupling only in having three nozzles instead of two. Owing to the main portion of a tee being the duplicate of a coupling of the same size, any 2″ coupling or 2½″ coupling may be replaced by a 2″ or 2½″ tee without disturbing the main line. A modified form of tee called a "Y"-box is used where the service makes an angle of 45° with the main line. A four-way or cross-box, really a double tee, admits of two services being taken from one joint.

Mains are so placed in the ground that the positive and negative conductors are on one side of a vertical plane through the centre line of the tube, while the neutral or balancing wire is on the other, as shown in Fig. 12. The side of the tube which the neutral is on is called the inside, because the main tube is so placed that the neutral copper is nearest to the curb line. The feeders are laid symmetrically, with the right hand copper as the positive conductor as the tube leaves the station. Services are never taken from feeder lines. A service to the side of the main line marked inside, and called an inside service, is shown in Fig. 10, while Fig. 11 shows a service to the opposite side, called an outside service. On this basis all services are classed as either outside or inside. The same distinction is made with regard to bends in a main tube, all bends in which the neutral joint is shortened, or before on the inside of the curve, are inside elbows; while those in which the neutral joint is the longest of the three joints, are called outside elbows. The table appended gives the size of service joints required for different service connections, the branch line not being larger than 120,000 circuit mils.

Size of Main Line.	Joints Required for Inside Service.
No. 80 to No. 300.	3 Short Branch Joints.
No. 350 to No. 500.	3 Long Branch Joints.
	For Outside Service.
No. 80 to No. 500.	2 Short & 1 Long Branch Joints, 1 Branch Link

For larger services there is provided a complete tee joint, which consists of the necessary main line coupling joints with the branch joints attached. The combinations of elbow joints given below cover a range of 18° on each side of their mean position.

In referring to what constituted a feeder line, it was stated that it was a line from the source of current to some centre of distribution from which mains radiated. This requires that the feeder should be split up or branch out, or, what is the same thing, that it should be connected to two or more mains. The safety catch box is designed to accomplish this object. Inside of a safety catch box all wires of like polarity are connected together, thus allowing the current coming in on one or more lines to split up and supply the remaining lines from which customers obtain their current for light or power. The safety catch box serves then, first, as a centre of distribution; second, as a centre of equalization of electrical pressure between the different parts of the system.

It also affords a ready means of inspecting and testing any line, or of disconnecting a line from the system when work is to be done on it, such as the connection of services, etc. It may be noted here that men thoroughly familiar with the work do not find it necessary to interrupt the current while making service connections.

In Fig. 13 is shown a perspective view of a ten tube safety catch box, *i. e.*, one intended for connection to ten or any less number of lines of tubes. The safety catch boxes are built in three sizes for use with four, six and ten lines respectively. A 4-tube box has four stubs, short lengths of pipe, for connection to as many lines of main tubes. A 6-tube box has four stubs for connection to mains, and two larger stubs for connection to either feeders or mains. A 10-tube safety catch box has eight stubs for connection to mains, and two for connection to either feeders or mains. The top of the box is closed by two covers, the lower of which is bolted down upon a rubber gasket, making a water-tight joint. The upper or top cover, shown in position in Fig. 13, is heavily ribbed and takes the jar and pound of traffic. The engraving, Fig. 14, gives an idea of the general arrangement. The lower half of the jacket has nozzles cast on it into which the short pieces of pipe forming the stubs are screwed. The pipe used for stubs to which mains are to be connected is 2½″ inside diameter, and all the regular 2½″ fittings can be used with

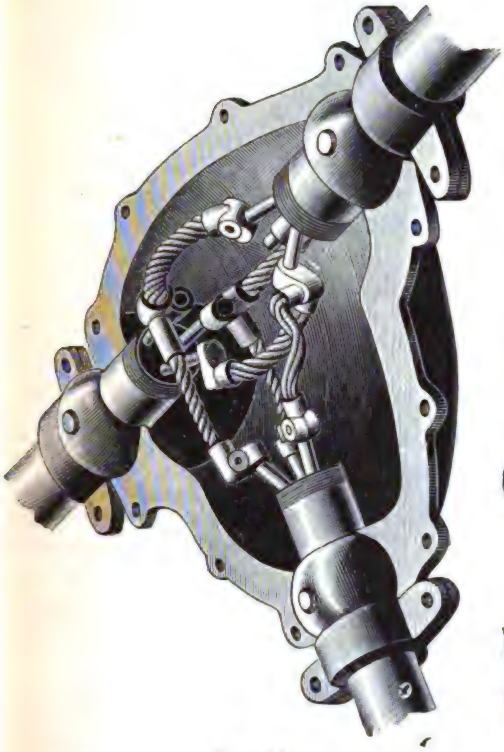

FIG. 10.

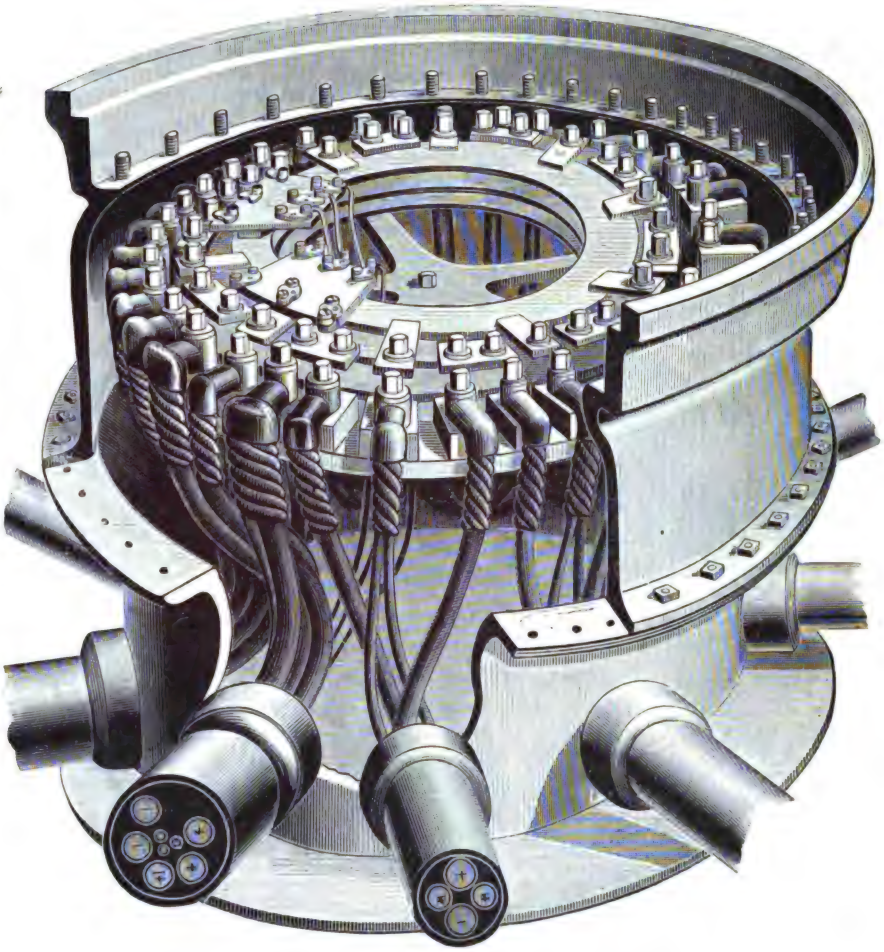

FIG. 14.

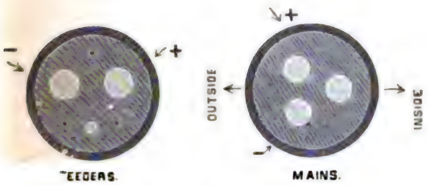

FIG. 12.

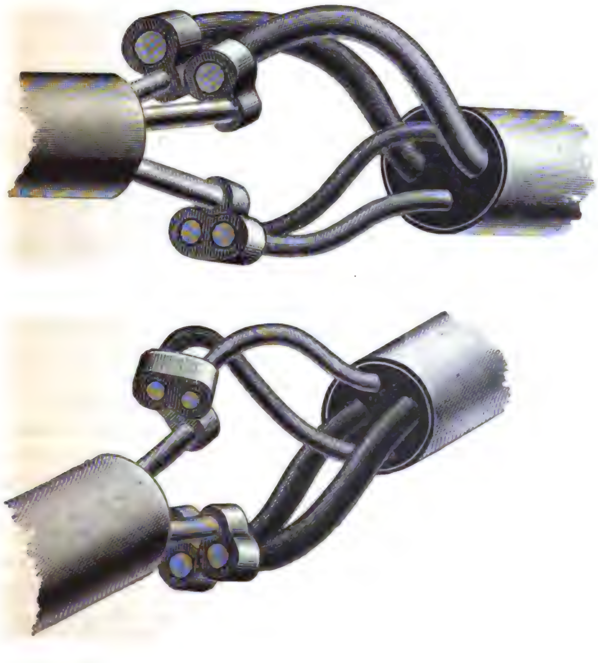

FIG. 15.

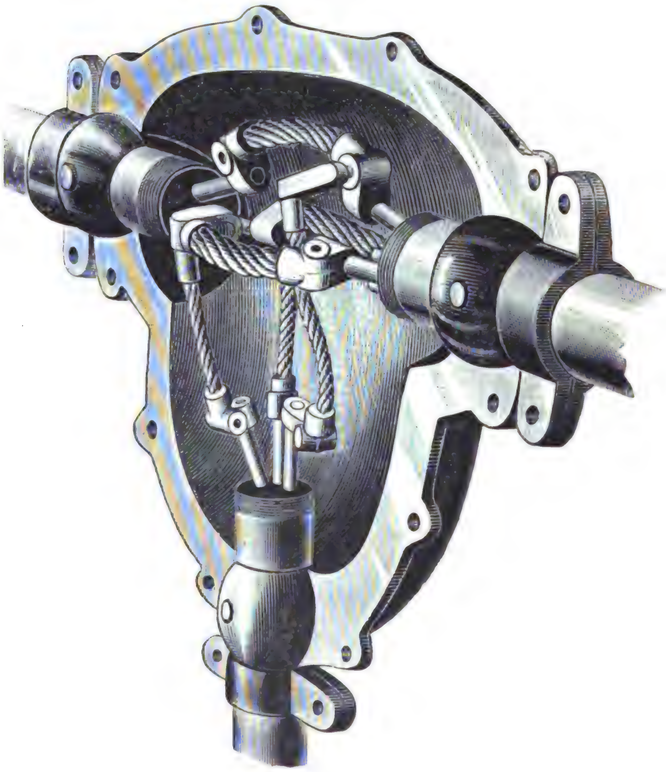

FIG. 11.

THE EDISON SYSTEM OF UNDERGROUND ELECTRIC TUBES.

it. The feeder stubs are of 3½" pipe, and take a special clamp which fits the elbow boxes, and is screwed, and not clamped, onto the stub. The cables in the stubs run to terminals which are connected by safety fuses to copper rings, having terminals opposite to all cable terminals of like polarity. The positive and negative cables in the feeder stubs are of double the size of the neutral cable, because the neutral wire is always smaller than the positive or negative copper, usually only one-third the size of the positive or negative conductor. Fig. 15 illustrates the convenience of splitting the neutral conductor in main stubs. The left-hand figure shows a main with the neutral on the left hand facing the safety catch box, while the

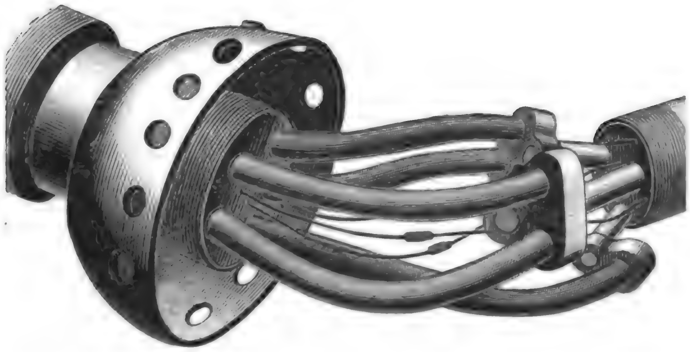

Fig. 16.

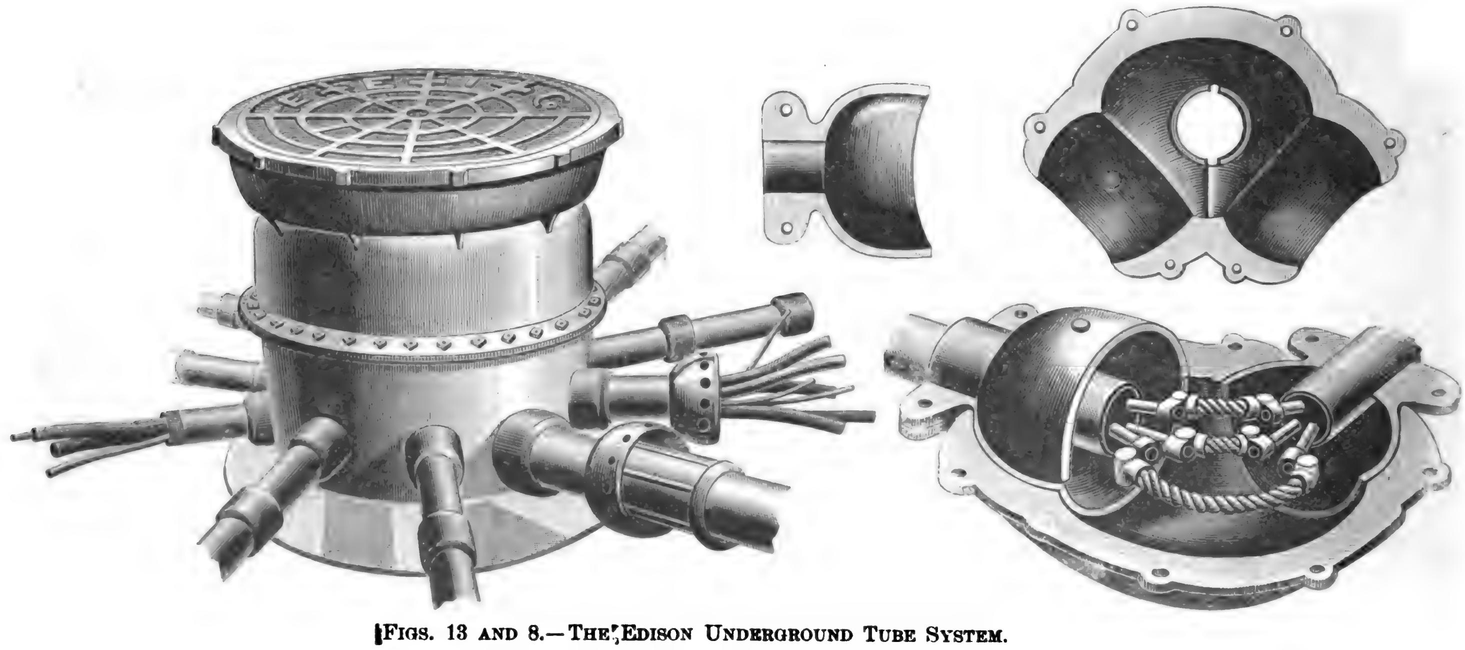
other sketch shows a right handed neutral connected to a similar main stub. The top cable in a main stub is always connected to the positive pole of the feeder through the terminals inside the box. Fig. 16 shows a feeder jointed to a feeder stub of a safety catch box. The sockets by which a cable in a stub is connected to a rod in a tube, as shown in Figs. 15 and 16, are called cable sockets. A hard rubber board secured on top of the rings and shown in



Figs. 13 and 8.—The Edison Underground Tube System.

Fig. 14 carries the terminals needed for the small cables running in the feeders and called pressure wires. In this way the electrical pressure at the box can be transmitted through these small cables to the station, and there measured by a suitable voltmeter enabling the attendant to maintain the right pressure under varying loads.

The system may seem burdened with details, but when the consideration comes in that the system takes the current from the dynamo and delivers it to the customer, that a tube is equivalent to three ducts in a conduit and three insulated cables, and that the system has a flexibility far ahead of any underground method of either gas or water distribution, we see that it is, when compared to its work, exceedingly simple. Ten years of experience have enabled the Edison company to produce their standard system of the present freed from the weakness of the original types and have entirely obviated all liability to burn-outs. They manufacture also a complete 2-wire system and a telephone conductor system. They have made many special forms, and are prepared to furnish plans and estimates for any class of underground work.

ELECTRIC MOTIVE POWER ON ELEVATED RAILWAYS, AND ITS PRACTICAL APPLICATION IN CHICAGO.[1]

BY W. N. SMITH.

This thesis is an attempt to show the feasibility of substituting electricity for steam on the elevated roads, as a step toward its general application to longer lines of railway. The historical matter treats of the experiments made on the Manhattan Railway and elsewhere, by Messrs. Leo Daft, F. J. Sprague, and Stephen D. Field.

The principal considerations affecting the problem are discussed in detail, and original designs for the motor and trucks of a motor car, are presented. The writer thinks the motor car preferable to the separate locomotive, and would adopt a 3-wire overhead system, the track being the neutral conductor, and the copper lines being over each track. Each motor car is of about 176 h. p. and will haul two loaded coaches of the usual type.

The power station is equipped with triple expansion engines of 500 h. p. and two multipolar Gramme ring dynamos to each engine. Practical conditions are taken in Chicago, for the three lines now being built there, and the cost of equipment, both steam and electrical, are estimated, on a mathematical basis. It was found that the electrical equipment for ten miles of elevated railway trains to run at a maximum rate of 30 miles per hour, and 3 stops per mile, would cost about $1,078,000 more than the steam equipment; but the saving in fuel by an electrical system would be about $800 per day, with total efficiency, from engine to car axle, of only 55 per cent. Such a system would pay for its extra cost, simply in fuel saving, in less than 4 years; while its other advantages are so obvious that as soon as railroad managers can be convinced of its practicability, electricity will supersede steam.

1. Abstract of Graduating Thesis, Sibley College, Cornell University.

THE EVANS FRICTION CONE IN A COMBINED LIGHT AND POWER PLANT.

Considerable interest is felt among electrical engineers in the system of the Evans Friction Cone Company, of Boston, as an economical and trustworthy means of frictional driving between engines and dynamos. By the use of this system dynamos can either be driven direct from the engine or from counter-shafting when a large engine is used. A remarkable reduction in the space required for an installation is the result, while the efficiency is largely increased by the avoidance of belts, making the driving practically equal to a direct connection.

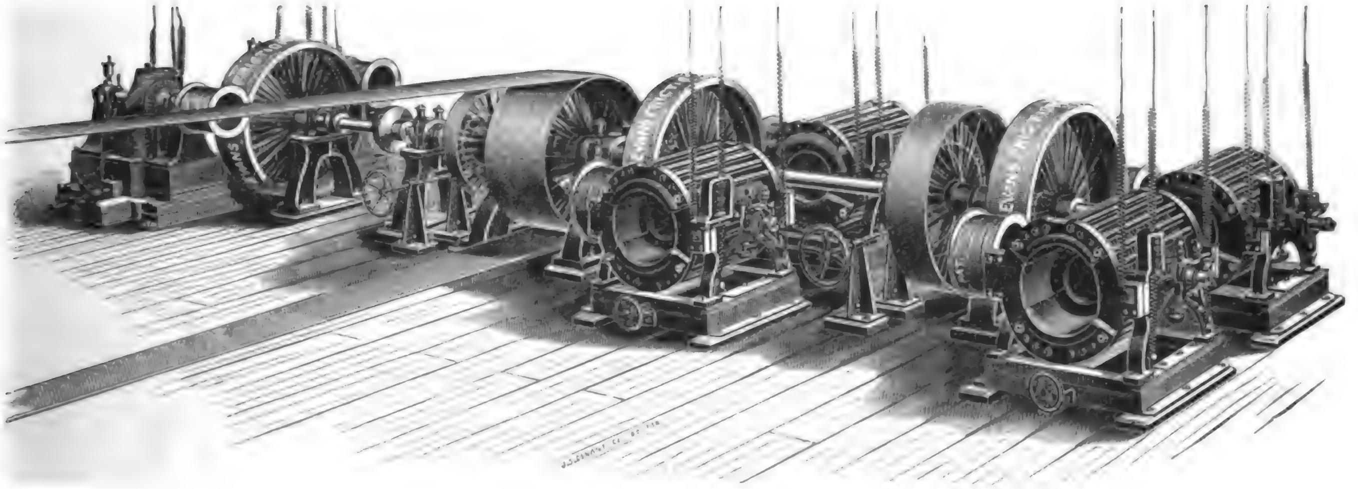
The line shaft shown in the engraving is driven from a compound Ide engine by means of the large belt shown. The two machines at the extreme left of the cut are each 60 h.p. Thomson-Houston railway generators, both running on the same circuit. The power on these two machines varies from practically nothing, to 140 h. p., many times an hour. All of the four dynamos shown at the right are Thomson-Houston "L.D." machines, each with a capacity of 50-1200 c. p. arc lamps, and each machine is fully loaded. The speed of the line shaft is 300 revolutions per minute. The driving pulleys on the line shaft are 50 inches in diameter. The speed of the railway generators is 1150 revolutions and that of the arc dynamos is 820.

The electric company is now putting in another large Ide engine and will belt direct to a continuation of this line of shafting and connect to the present shaft with a clutch coupling. On this continuation more dynamos will be placed and all will be driven by the Evans system. The dynamos, it will be noticed, are arranged so that one pulley drives two machines, and in such a manner that each dynamo can be stopped and started without slowing the engine, independently of the other machines. By putting two dynamos on one pulley the pressure on the shaft bearing is relieved, and the plant takes up the least possible amount of space.

The generators are running street railways and the arc machines street circuits.

The station illustrated is at (Farmers) Attleboro, Mass., and is owned by the North Attleboro Steam & Electric Co. They have also a station at North Attleboro, Mass., and will move some of their dynamos from North Attleboro to this new station this summer. The engine was installed by Messrs. John Post, Jr., & Co., and is a compound condensing Ide engine. Mr. H. M. Dagget, Jr., is manager of the company, and expresses himself as being highly satisfied with the efficiency of the entire plant.

Another field in which the Evans friction cone is being introduced is that of marine work. Few vessels have much spare room and hence anything effecting economy of space is welcome.



Light and Power Plant Driven by Evans Friction Cone Pulley.

THE PATTEE LAMP HOUR RECORDER.

The rapid strides which central station lighting for large areas has made of late years, have brought incandescent lamps into many places distant from the stations, the more so since the competition between the direct and alternating current systems of distribution has tended to stretch out the area supplied by each station. In this way many places which had not been able to install an isolated plant have been given the necessary luxury of incandescent lamps. The usual basis of charge for the current supplied has been the number of lamp hours at the consumer's place, *i.e.*, the number of lamps multiplied by the number of hours that they were burning. In many places, especially large business houses, where the lights are manipulated by gang switches, the lamps controlled by each switch are all turned on or off together. Then it is only necessary to keep count of the number of hours they were burning in order to compute the charges.

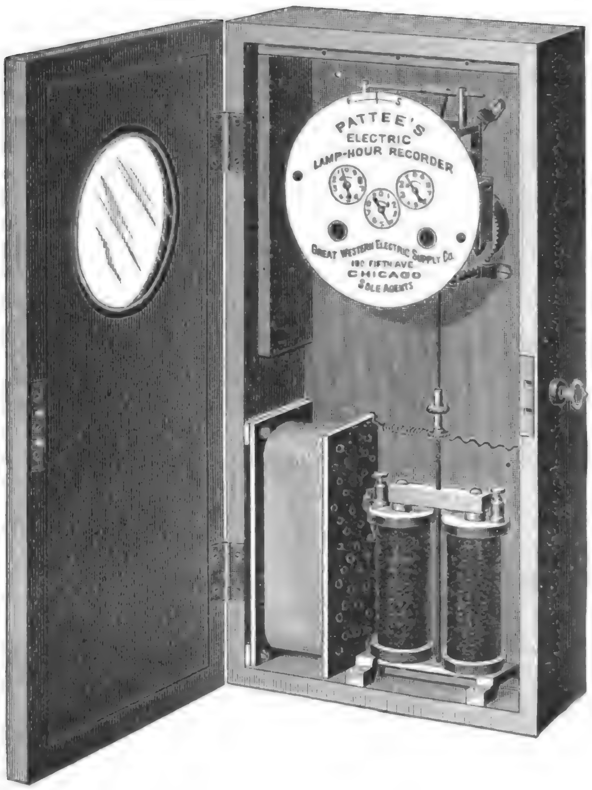
The meters in general use will give the number of hours only indirectly, hence the need of a simple and reliable counter for use with incandescent lamps has long been felt. This want is met by Pattee's electric lamp recorder, an instrument now being brought out by the Great Western Electric Supply Company, of Chicago. The cut (page 10) shows it with the door to the enclosing case opened. A clock-work with two powerful springs intended to run the recorder 720 hours, has three dials registering the hours, tens and hundreds. The inverted horse-shoe magnet, mounted on a brass plate below the clock, has its coils connected in series with the german silver resistance shown right beside it, the whole being connected in shunt with the lamps. The armature of the magnet is hung from a slender rod, and by its weight acts through a bell-crank lever as a brake to the escapement-wheel of the clock. When the current to the lamps is turned on, the armature is drawn up, and, acting on the lever and brake, at once releases and starts the escapement. As soon as the current is stopped, whether by the switch near by or by the shutting down of the station, the armature falls and stops the clock.

Thus the clock only runs while the lamps are burning, and the dial readings give the number of hours directly.

The whole apparatus is well built, and seems to have nothing about it which could get out of order. The german silver wire is wound on a bobbin with perforated heads, and has air spaces between the layers. The turnbuckle shown in the middle of the rod to which the armature is fastened, serves to adjust the play of the armature and its distance from the magnet poles. The lever, slide and brake are very neatly arranged, giving a positive start to the escapement and stopping it instantaneously.

The recorder is mounted in a walnut case like a clock, the dial being visible through a glass plate. A clock assures the current supplier that the instrument is not being tampered with, while the direct reading dial should give the consumer confidence in the correctness of the readings.

As ordinarily built, the coils have such a resistance that on a 110 volt circuit, the energy consumed is only 10 watts. By suitably varying the resistance, the Pattee recorder



THE PATTEE LAMP HOUR RECORDER.

can be adapted to currents of any pressure. Moreover it can be adapted for use with multiple, series, series-multiple or multiple-series lines and also alternating currents. There is no mystery or uncertainty about its operation.

POWER STATION, CITIZENS' STREET RAILWAY, INDIANAPOLIS.

THE Power Station for the Citizens' Street Railway Company at Indianapolis, Ind., is a handsome brick structure, as represented in Figs. 1 and 2 on the adjoining page. It is of sufficient capacity to contain 23 Thomson-Houston railway generators, and at the same time provide office room and a general machine shop.

The boiler plant consists of 3 Hazelton boilers, fitted to burn natural gas, and also arranged with furnaces to burn coal, as shown by the 3 extensions to each boiler on the plan. The gas burners in each boiler are located in such a manner that they do not interfere in the slightest with the coal furnaces, it being possible to make a change from gas to coal at a moment's notice. This is a very great advantage over the ordinary practice, as it is customary to place these burners on the grates, which, in case it was desired to use coal, would have to be removed, a by no means easy task.

The engines are so arranged and connected that any number can be run at the same time, and any one can be started and stopped while the remainder of the plant is in operation. The shafting is made of the best quality hammered steel and is supported by ball and socket self-oiling bearings. This is the first system that has been equipped upon this plan, and it is highly satisfactory. The steam piping for this plant is of ample capacity and so arranged that when the whole plant is in operation every detail will be of proper size and proportion.

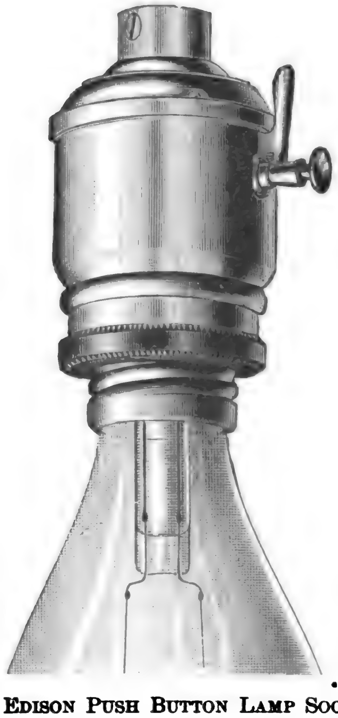
The feed water for the boilers is first passed through a Hoppes purifier which removes the impurities and heats the water at the same time up to boiling point. From this heater the water is pumped by Barr duplex pumps into the boilers. Everything about the feed water system is arranged in duplicate so that in case of accidental injury, operations would in no way be interfered with.

The general arrangement of this installation is shown by the cut representing a section across the engine and dynamo room. The entire installation rests upon masonry, consisting of a concrete base with the brick work on top laid in cement, and everything about the plant is constructed in the most substantial manner possible, and its operation is ample proof of the thorough workmanship and good material employed.

The engine, which has just been put in operation, was built by the Wheelock Company, of Worcester, Mass. The entire installation was planned and erected by Mr. L. H. McIntire of the Railway Engineering Department of the Thomson-Houston Electric Company. The work of installing the plant was in charge of Mr. W. S. Twining.

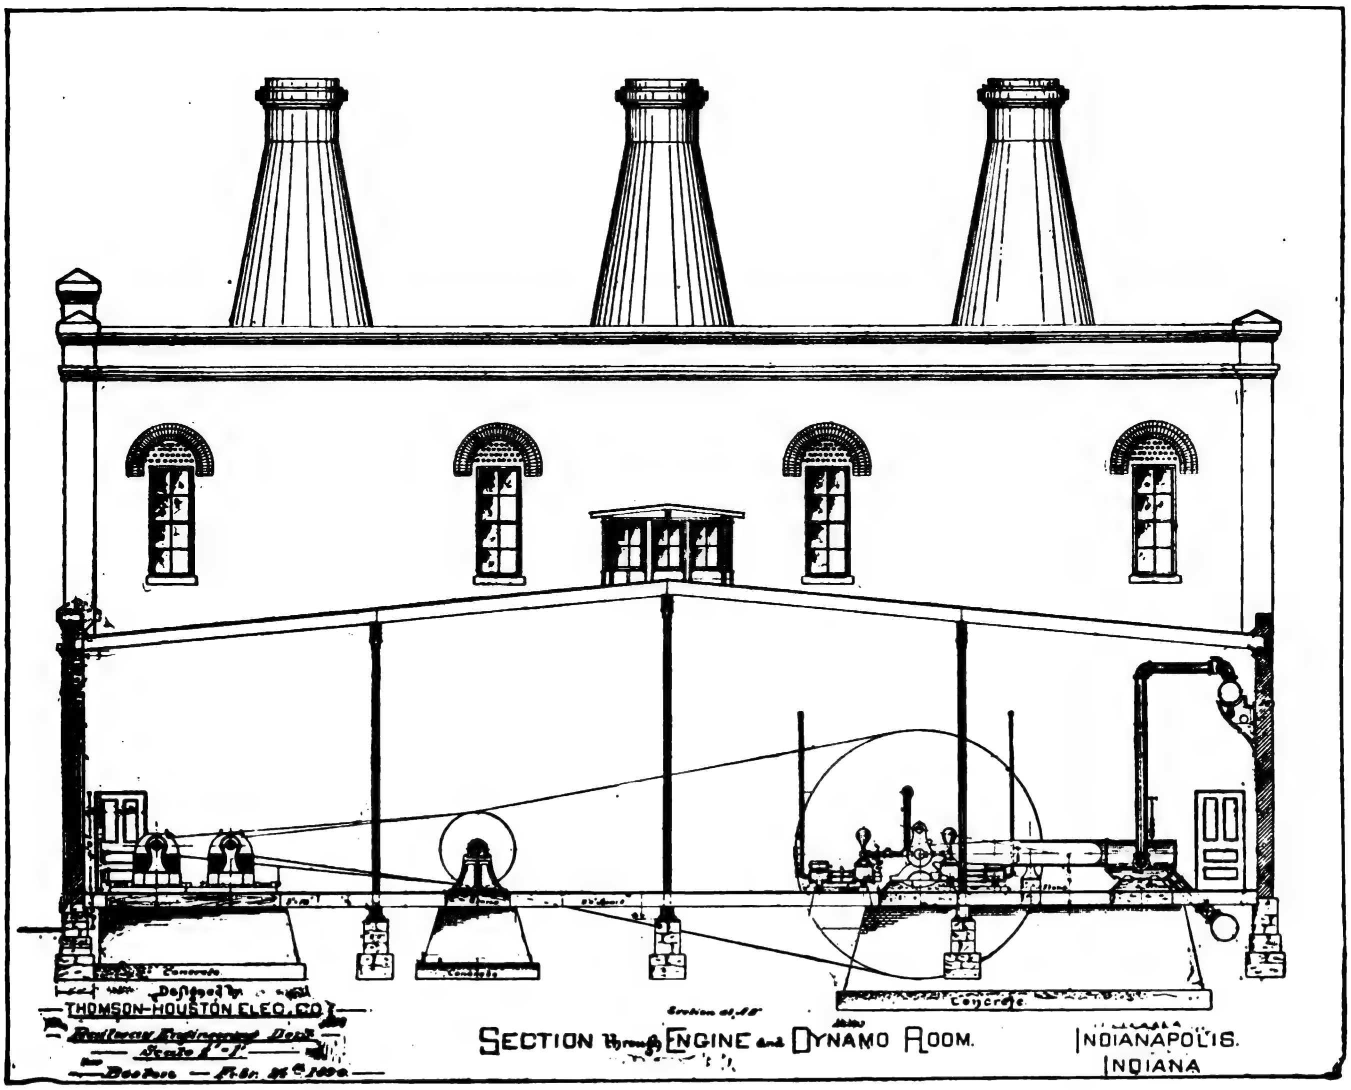
NEW EDISON LAMP AND PUSH BUTTON SOCKET.

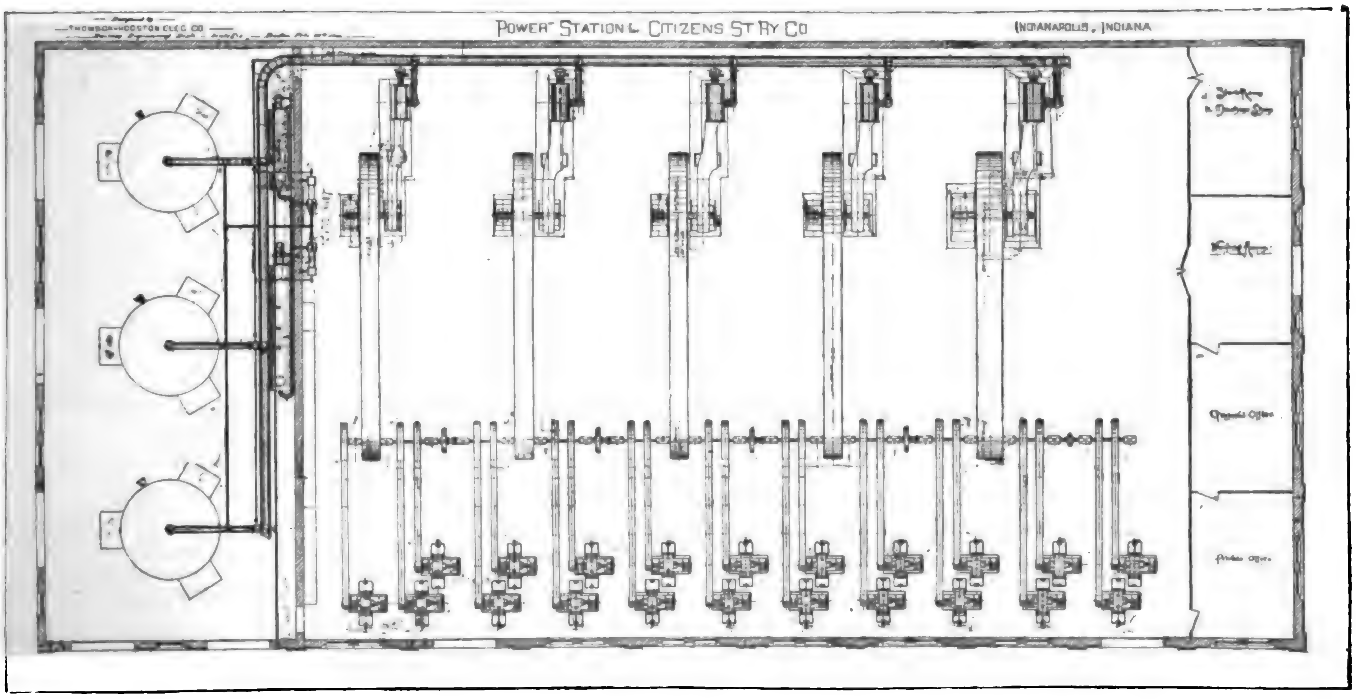
THE usual form of switch employed on incandescent lamps is so constructed that when the lamps are used as drop lights suspended from flexible cords, or attached to flexible fixtures, it requires the use of both hands to light or extinguish the lamp. In order to avoid this inconvenience and to permit of the easy lighting and extinguishing of the lamp, the United Edison Mfg. Co. have recently



NEW EDISON PUSH BUTTON LAMP SOCKET.

brought out the switch socket illustrated in the accompanying engraving. As will be seen this consists of a push button which, when pressed, closes the switch, and is maintained in position by a spring-latch, provided with a short lever extension. By pressing the latter the push is released and a spring forces the button out, thus opening the switch. By the use of but one hand, therefore, both operations can be conveniently performed.





FIGS. 1 AND 2.—ELECTRIC POWER STATION, CITIZENS' STREET RAILWAY, INDIANAPOLIS.

SOME EXPERIMENTS UPON ALTERNATING CURRENT APPARATUS.[1]

BY HARRIS J. RYAN.

It is well known that when the core of a transformer is heated under certain favorable conditions the secondary will deliver electrical energy in amount considerably greater than when the core is not heated, and that this is done, too, without an increase of energy that is supplied to the primary. In fact, we are told that on heating the core of the properly constructed transformer, there will be obtained a diminution of energy taken up by the primary, and a considerable increase in that given out by the secondary.

In some recent experiments made in the Physical Laboratory of Cornell University it was not possible to obtain the above effect. Mr. L. B. Marks, a student in electrical engineering at Cornell, made an apparatus that differed materially from the

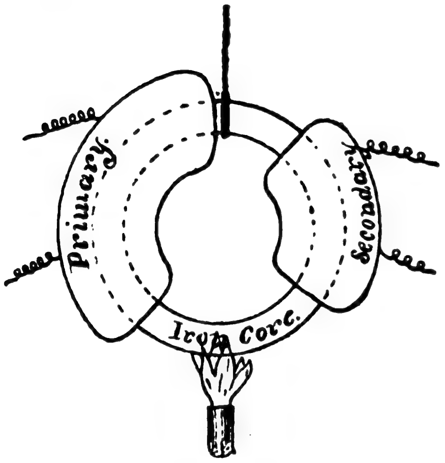


Fig. 1.

forms that were first made use of, in which he found this phenomenon very marked.

For two reasons we think that the details of the performance of Mr. Marks' apparatus to be of interest to the members of the Institute. First, that they indicate clearly the source of energy in the phenomenon observed with his apparatus, and, second, that they show in exaggerated form certain phenomena that must be done away with in a transformer that is to be used for incandescent lighting.

A good idea of the apparatus will be obtained by a glance at Fig. 1. The core consisted of well rusted wire rings 1.1 cm. thick, and of a mean diameter of 17 cms. each. The number of turns on the primary was 500 and on the secondary 155. The size of

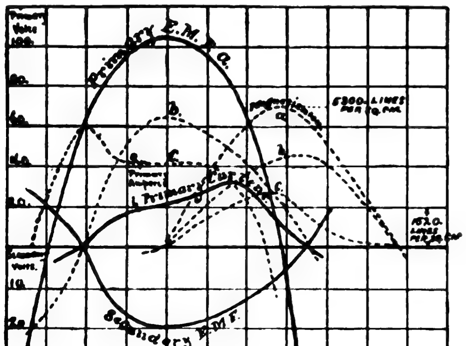

Fig. 2.

bare copper wire in each was No. 18 B. & S. G. The wire was insulated with asbestos paper, and because of its thickness the primary and secondary turns with their insulation occupied a space of abnormal proportions.

Resistance of the primary.............. 1.65 ohm.
" " " secondary........... 0.71 "

The maximum magnetization used in the core in any of the experiments here described was not above 3,000 lines per sq. cm.

1. A Paper read before the American Institute of Electrical Engineers, June 17, 1890.

The diagrams, Figs. 2, 4, 5 and 6 represent graphically the observations that were made with the apparatus. From these diagrams are deduced the following results:

SECONDARY OPEN. NO EXTRANEOUS HEAT APPLIED.

Temperature of the core........... .... 97.5° C.
Primary E. M. F.......................... 75.6 volts.
Secondary E. M. F........................ 16.4 "
Ratio $\frac{75.6}{16.4}$.............................. 4.6
Secondary current.......... .... 0.0

Temp.	Loss in Core.	Primary Watts.	Secondary Watts.	
2. 97.5° C.	122	122	0.0	
4. 300° C.	72.	72	0.0	
270° C.	79 (Estim.)	79	0.0	Corrected for rests of sec.
5. 99° C.	117	131	24	
6. 270° C.	80	116.7	36.7	

Primary, 90 volts; 120 reversals per second.

Data are presented in the latter part of this paper showing that it is correct to assume for small ranges that the loss in the core is proportional to the square of the primary E. M. F. We can therefore deduce from Table I the results that would have been obtained with 90, volts as the primary E. M. F. for the four experiments.

The figures in Table II show clearly that the loss in the core is greatly diminished when its temperature is elevated, *i. e.*, when heat is applied, and that the loss in the core is practically independent of the output. The results indicate that with the secondary open, and the primary at a difference of potential of 90 volts without heat applied, the core came to a temperature of 97°C., and dissipated 122 watts; then by the application of heat with the Bunsen burner, as indicated in Fig. 1, the temperature of the core was raised to 300°C., and was found to take up 72 watts. Now, if we assume the changes in watts dissipated in the core to be ap-

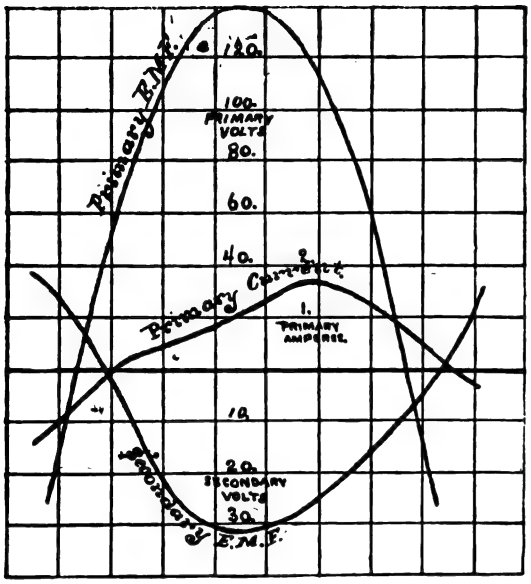

Fig. 4.

proximately proportional to the changes in temperature that produced the same, then we see by estimation that 79 watts would have been dissipated by the core at 270°C., while 80 watts were found to have been dissipated by it at that temperature when the secondary was closed and gave an output of 32 watts.

It is perfectly plain, therefore, why we can close the secondary, take from it 32 watts, elevate the temperature of the core 170°C., and have the primary take up 5 watts less than when the secondary was open, and the core at the lower temperature.

Since the effect is due only to the fact that the core takes up

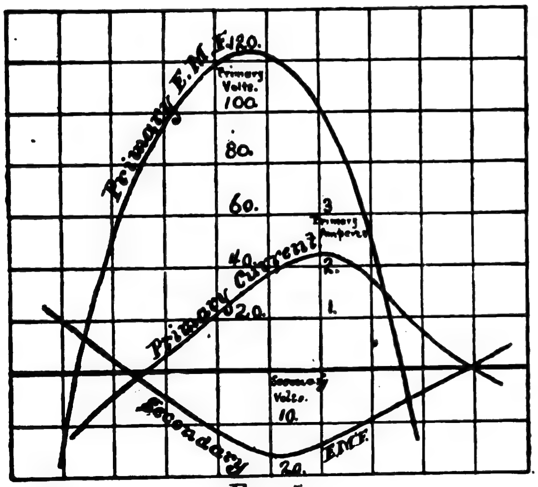

Fig. 5.

much less energy at higher than at lower temperature, and since the core can dissipate energy through *Foucault current* and *hysteresis* phenomena only, it is due to a decrease of the total energy dissipated through changes in the above phenomena.

A rise of temperature in the core will increase its specific resistance, and therefore diminish the energy dissipated by Foucault currents. For decided degrees of magnetism it is known that the permeability of iron increases when it undergoes a rise of temperature. It was thought probable, therefore, that the energy dissipated per cycle of magnetization and demagnetization would be decreased with an increase of temperature.

Experiments were made in the Physical Laboratory of Cornell University by Mr. Arthur Herschel on the hysteresis at high temperature of a cast iron ring, 12.3 cms. in diameter, that furnished a closed magnetic circuit, the length of which was 38.5 cms. The ring was wound with 80 turns of No. 8 wire cable that had a mica insulation. The highest temperature to which the ring was subjected was 360°C. The results of these experiments are represented graphically in Fig. 7.

One interesting thing about these results is that for degrees of magnetization below 2,000 lines per sq. cm., the variation of temperature below 360°C. does not change the magnetic character of the iron by an observable amount. Now, if wrought iron behaves in a similar manner then the decrease of energy dissipated

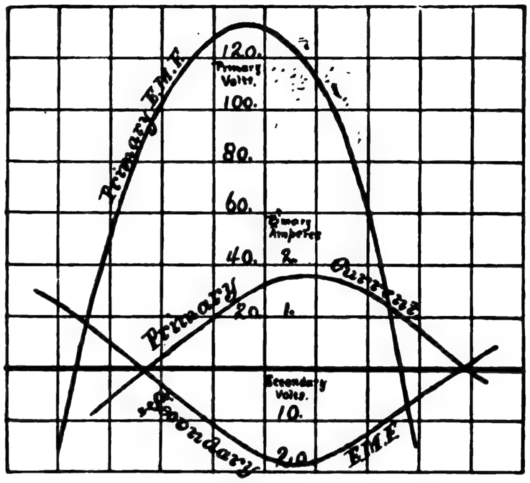

Fig. 6.

in the apparatus of Mr. Marks was not due wholly, nor in part, to a diminution in the hysteresis of the iron. It was, therefore, due entirely to the diminution in Foucault currents, caused by the change of the resistance of the iron. A liberal estimate for the hysteresis of the core is 20 watts, whence the Foucault energy dissipated by the core at 100°C. and 90 volts was 102 watts, and at 270°C. and 90 volts it was 60 watts.

The range of temperature that produced this change was 170°C. The magnetization for each condition is the same, so that it is fair to assume that the E. M. F. setting up the Foucault currents is the same, and that, therefore, the energy dissipated by Foucault cur-

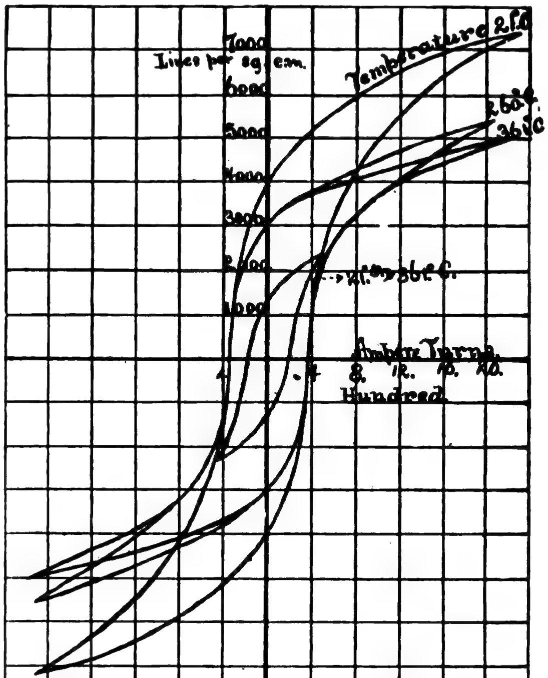

Fig. 7.

rents will diminish as the resistance of the iron is increased by the elevation of its temperature. This gives us a rough determination for the temperature coefficient of the iron to .4 of 1 per cent. per degree centigrade, which agrees with Matthiessen's determination and furnishes a fair check upon the conclusion just arrived at.

The second interesting feature about the performance of Mr. Marks' apparatus lies in the fact that the ratio of primary to sec-

ondary turns was 3.2, while the ratio of primary to secondary E. M. F. varied from 4 to 8. In this it exhibited exceedingly bad regulation, so that by examination of the diagrams, Figs. 2, 4, 5 and 6, we can see in exaggerated form the trouble it is so hard to get rid of in transformers to be used for incandescent lighting. Any one of these diagrams shows that a large portion of the lines of magnetization that was set up about the primary were not set up about the secondary. That is to say, the counter E. M. F. that

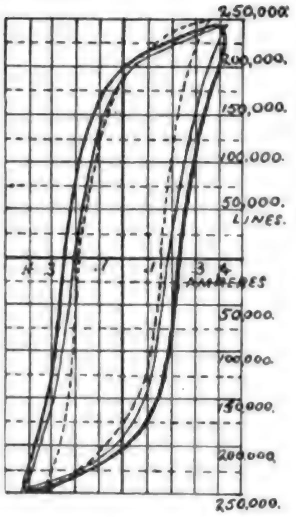

FIG. 8.

is produced in the primary is due to the magnetization through it that also took place through the secondary, plus the variation of magnetization that was set up in its own air space, and that leaked by the secondary through the air. When the transformer furnishes current this difference becomes greater and greater because of the increased current in the primary, and the setting up of a counter-magnetization by the secondary current in its own air space that still further reduces the magnetization through it.

Fig. 1 shows the primary disposed on one side and the secondary on the other side of the annular core. The insulation was

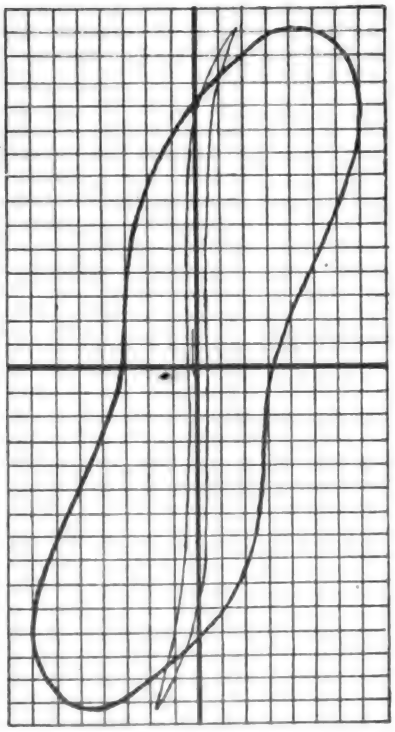

FIG. 9

produced by thick asbestos paper that produced large air spaces between the turns in which magnetization was produced.

In Fig. 2 E. M. F. curve b is the counter E. M. F. in the primary produced by the magnetization through it that also took place through the secondary, and which is obtained by multiplying the secondary E. M. F. by 3.2, the ratio of the turns. E. M. F. c. is the curve of counter E. M. F. in the primary that was produced by magnetization through the primary that did not take place through the secondary. This is obtained by subtracting E. M. F. b from E. M. F. a. E. M. F. c. is seen to be approximately proportional to the rate of change of the primary current, which suggests magnetization that is set up through the primary that is proportional to the primary current, or that which is set up in the air, or, in a magnetic circuit compounded of iron and air.

In the same figure the curves of magnetization a and b are obtained graphically from the curves of E. M. F. a and b by the method shown in Fig. 3. This method is found to be fully as accurate and requires much less time and is more simplified than the analytic method making use of Fourier's theorem.

By substracting b from a we obtain c, the curve of magnetization that was produced through the primary and not through the secondary. This curve of magnetization c is seen by the diagram to be of about the same form as the current curve, but to lag behind the latter, which indicates that it was magnetization that was produced through air and air and iron.

During the discussion, at a recent meeting of the Institute, the question was asked whether measurements of Foucault currents

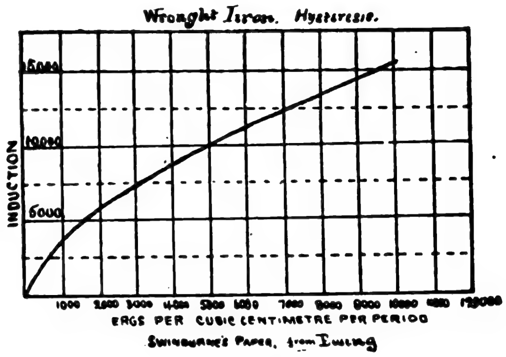

FIG. 10.

and hysteresis as separated from each other had ever been made.

There can be no doubt but that we do have separate determinations of those quantities when we have determined the energy dissipated in a magnetic circuit of iron by rapid cycles of magnetization and demagnetization, and the energy dissipated by static hysteresis for the same rapidity and degree of magnetic changes as determined from a Ewing card observed through slow magnetization and demagnetization.

The diagrams Figs. 8 and 9 are two good illustrations of such determinations. In Fig. 8 the outer card represents the card ob-

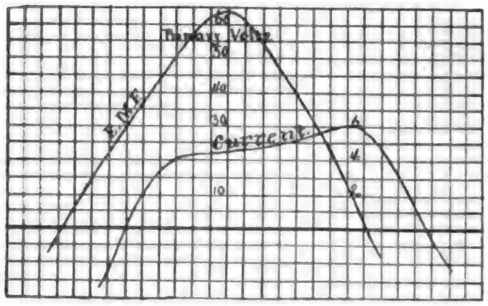

FIG. 11.

tained from the exciting current and magnetization curves taken carefully at 138 reversals per second from the ten-light transformers upon which the tests were made, that were communicated to the Institute by the writer at the last December meeting. The inner card drawn in a full line in Fig. 8 is the Ewing card of static hysteresis. This transformer, on being taken apart, was found to have its discs insulated with paper, so that the statement made by the writer in December with regard to the lamination of this transformer was erroneous in this particular. Foucault currents should therefore be found to be quite absent, as the diagram in Fig. 8 indicates. A study of these cards does not reveal that which can be recognized as a trace of viscous hysteresis, and they differ only by an amount of Foucault current energy that is represented by a small current lagging approximately an eighth of a period behind the primary impressed E. M. F.

In Fig. 9, the outer card is deduced from the current and magnetization curves that are represented in Fig. 12. These curves were obtained with 195 reversals per second from a cast iron ring 8.6 cms. in diameter, and 2.7 sq. cms. in cross-section, wound with 200 turns of wire that had a negligible resistance.

In Fig. 9. the inner card is the card of static hysteresis. In Fig. 12, the lower broken current curve is that of the exciting

current curve drawn in from the inner card of Fig. 9. By subtracting this current from the one that was observed, we obtain the upper broken current curve, which is the current that exists

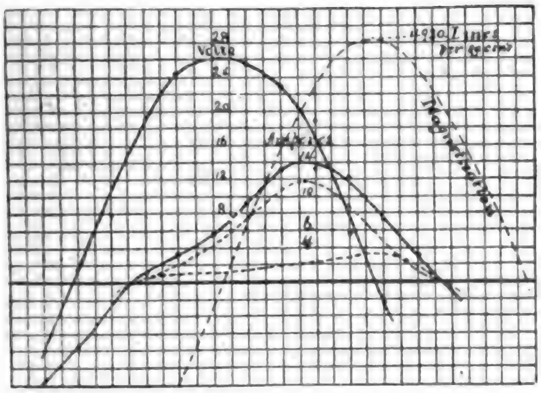

FIG. 12.

to supply the Foucault current energy in the core. The point to be noticed from the two extreme cases here taken up is, that in each case the curve of current supplying the Foucault current

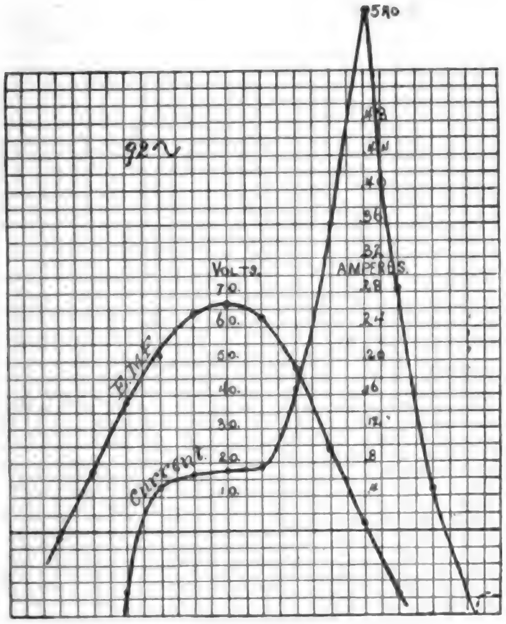

FIG. 13.

energy is about one-eighth of a period behind the impressed E. M. F. Messrs. Forhenbaugh and Sawyer, students in electrical engineering at Cornell University, made determinations, the results

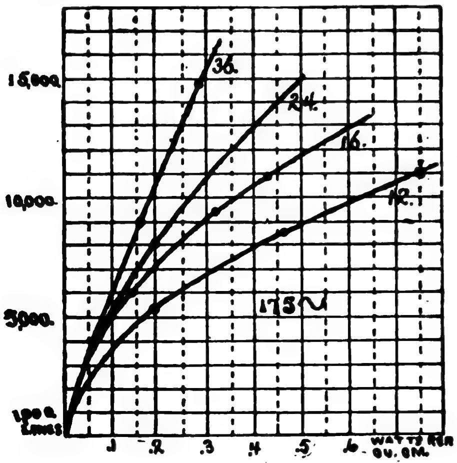

FIG. 14.

of which are given in Table III, of the amounts of energy that are taken up per cubic cm. in wrought iron wire cores of different degrees of lamination, at various degrees of magnetization, and at different periodicities, in which the oxydized surface of the iron was depended upon for insulation. They made use of four iron wire rings the mean diameter of each of which was 8.9 cms. and on each of which are wound 200 turns of wire that had a negligible resistance. Figs. 11 and 13 are given for illustrating the extreme variation in the character of the exciting current in going from the lowest to the highest degree of magnetization.

The result shows, on account of the presence of Foucault currents to a larger extent for the higher degrees of magnetization, a variation in losses as the square of the periodicity and the square of the magnetization. The results obtained with the several cores at the periodicity of 175 reversals per second have been plotted in Fig. 14.

Diam. 3.5 × 2.54.

The card of No. 36 wire agrees closely with Ewing's determination of static hysteresis for moderately soft wrought iron, and is therefore entirely free from Foucault currents. It is interesting to note that for the cores of No. 36, No. 24, and No. 16, there is but little difference in the losses for degrees of magnetization below 4000 lines per sq. centimetre.

Likewise, for the higher degrees of magnetization, it is seen that the loss is proportional to the magnetization, as Ewing's results on static hysteresis, given in Fig. 10, indicate they should be. Fig. 13 shows the effect of compelling the magnetization to be carried above the bend of the characteristic curve of the iron.

ELECTRIC RAILROADS FOR THE SOUTH.

Street railroads in Georgia appear to be a good investment, says the *Baltimore Manufacturers' Record.* Not long ago some capitalists from Kansas City, Mo., headed by Mr. S. M. Jarvis, of the Jarvis-Conklin Mortgage Trust Co., which has headquarters in that city, and Mr. D. B. Dyer, purchased the Augusta Street Railway and immediately began to make preparations to convert it into an electrical line. They are now pushing work very rapidly, and Augusta bids fair to have as complete a street railroad system as any city of her size in the South. The Augusta & Summerville Railroad has also decided to adopt electricity as a motive power. This will give Augusta some 25 miles or more of electrical railroad. Savannah is just now the scene of a large street railroad deal. Nashville parties, among whom are I. T. Rhea and T. W. Wrenne, the latter being interested in a street railroad in St. Augustine, Fla., have purchased a considerable amount of street railway property in the "City by the Sea." It is not known definitely just what these men propose doing with their new acquisition, but it is supposed that they will convert it into an electrical line in about the same manner as has been done in Augusta. These same Nashville capitalists are rumored to have made large purchases of street railway property in Charleston, S. C.

A GERMAN ELECTRIC TARGET.

An electric target is one of the latest German ordnance inventions. It consists essentially of two parts, one the target itself and the other the electric registering apparatus. The target is made in sections. When struck by a bullet the particular section hit is forced back, together with its spring, by the force of the impact. The spring strikes a vertical lever and causes it to fall into a horizontal position. By this means electrical communication is established through contacts and a battery with the registering apparatus placed at the firing point, and an electric bell is rung simultaneously. To interrupt the circuit and stop the bell a cord is pulled and a brush passes over the face of the target, removing the bullet mark. At the same time the lever is restored to its original position.

EFFICIENCY OF THE TRANSFORMER.[1]

BY CALVIN HUMPHREY AND WILLIAM H. POWELL.

In pursuing this particular line of investigation it has been our endeavor to throw some light, if possible, upon the general subject of transformers and upon the action of iron when magnetized and demagnetized by an alternating current of high periodicity. And in order that the results obtained might have a practical bearing, the conditions of working were made to conform as closely as possible to the conditions under which transformer systems are operated in this country.

The question of the economy of the commercial converter as a transformer of energy has been frequently taken up, both from practical and theoretical standpoints, but with widely varying and conflicting results. The losses in the transformer of the closed circuit type have been considered large and inevitable, so much so, in fact, that Mr. Swinburne has introduced in England a new form of open circuit transformer known as the "hedgehog." It has been Mr. Swinburne's endeavor to obviate the dissipation of energy in hysteresis and Foucault currents in a part of the magnetic circuit, by having that circuit closed through air. But as will be seen later, the perfection of the transformer is to be met in a better grade or iron, rather than in any radical change in design.

The results presented in this paper are of especial interest as being supplementary to the work of Prof. Ryan and Mr. Merritt in the same line, which was presented to the Institute last December. The 10-light transformer which they tested was found to have a remarkably heavy loss on open circuit, which was shown to be due almost entirely to hysteresis in the iron. The transformer gave an efficiency of 86% at normal load and an "all-day" efficiency of about 40%.

In our work on a 40-light transformer of the same design,—the two coils placed side by side in a core of laminated plates, Fig. 1,—but of more recent manufacture, the loss on open circuit was found to be about one half as great as in the 10-light transformer. Its efficiency reached 96.2% at normal load, and the "all-day" efficiency would be about 90%.

The method employed in the work is substantially Prof. Ryan's method. The instantaneous values were obtained by means of a commutating device attached to the alternator. This device consisted of a wooden disc, mounted rigidly on the shaft of the alternator, with a steel contact at one point in its periphery, which made contact with a small piano wire brush once every revolution. The holder carrying the piano wire brush was attached to a second wooden disc carrying a pointer which moved over a scale and indicated the position of the brush for a given reading. By means of a clamp screw this second wooden disc carrying the brush and pointer could be conveniently set at any point. Now since the steel contact in the wooden disc is fixed relatively to the armature, it must share the ever varying E. M. F. of the armature. Then evidently if the brush which completes the circuit through the contact be altered in position, values can be obtained for different points on the curves of E. M. F. and current.

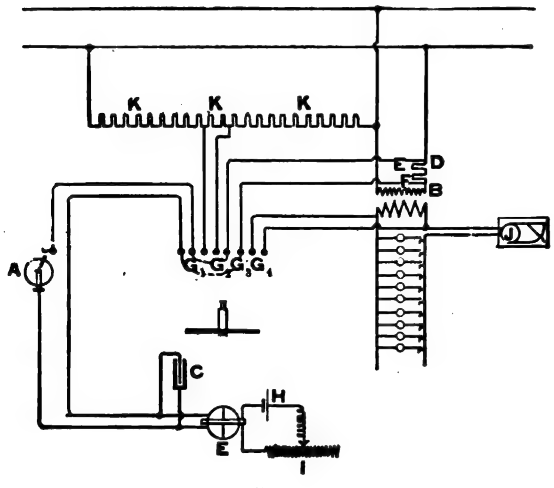
The Ryan quadrant electrometer was used to measure the primary E. M. F., secondary E. M. F. and primary current. A condenser was connected in multiple with the electrometer. The primary current was measured by the fall of potential through incandescent lamps placed in series with the primary of the transformer. These lamps were carefully calibrated with the standard instruments of the laboratory in order to know their resistance at different temperatures. Then knowing the resistance of the lamps, and the potential difference at their terminals, the current flowing at once becomes known.

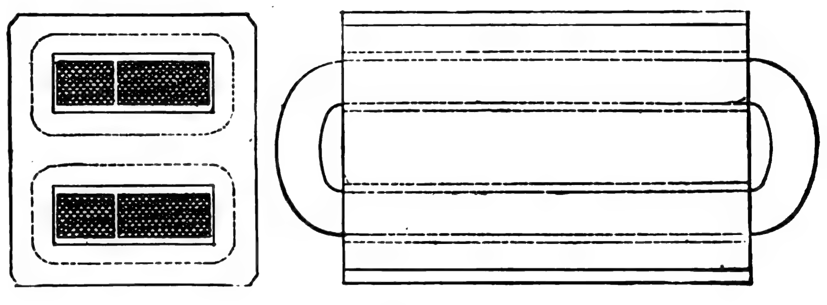
To measure the E. M. F., twenty-two 50-volt lamps were placed in series across the primaries. The electrometer was connected around two of these lamps, and the whole number calibrated in order to know just what part of the total impressed E. M. F. was measured. The secondary E. M. F. was measured direct. The secondary current was measured by means of an electro-dynamometer, which was carefully calibrated both before and after the experiments and was found to be constant. The commutating device was placed in series with the electrometer. Wires were run from the terminals from which the measurements were desired to a convenient switch-board.

In obtaining the Ewing card of hysteresis of the iron core of the transformer, current from a storage battery was sent through the secondary circuit, and the magnetization set up in the core was measured by the "kick" on a ballistic galvanometer in the primary circuit. The current in the secondary was gradually increased until the intensity of magnetization corresponded with the maximum magnetic density of the transformer when working on a 100-volt circuit. The current was then decreased, gradually, until zero was reached. It was then reversed and the method continued until a complete cycle of magnetization had been covered.

It is worthy of mention that this method which gives something so definite and fundamental in the treatment of the alternating current has only come into use within the past year, and the task of getting true instantaneous values of the complete waves of E. M. F. and current which has always been considered too tedious for ordinary patience to deal with was accomplished with ease in this work in forty-five minutes. A calibrated scale for the electrometer readings added very much to the facility with which observations could be taken.

The marked improvement of the 40-light transformer over the 10-light is due, we believe, to an improvement in the magnetic properties of the iron and a fewer number of turns in the coils, made possible by the better grade of iron. In the 10-light transformer Foucault currents were very effectually weeded out by the interposition of sheets of paper between the laminated sheets of iron; in the 40-light, the oxide of iron on the surface of the plates was the only safeguard against Foucault currents.





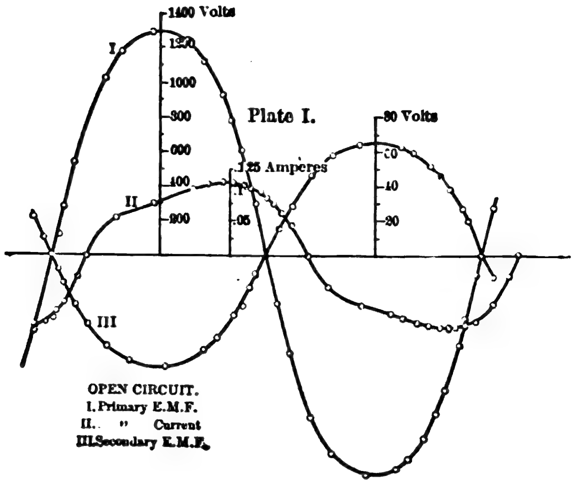
Figs. 1 and 2.—Humphrey & Powell on the Efficiency of the Transformer.

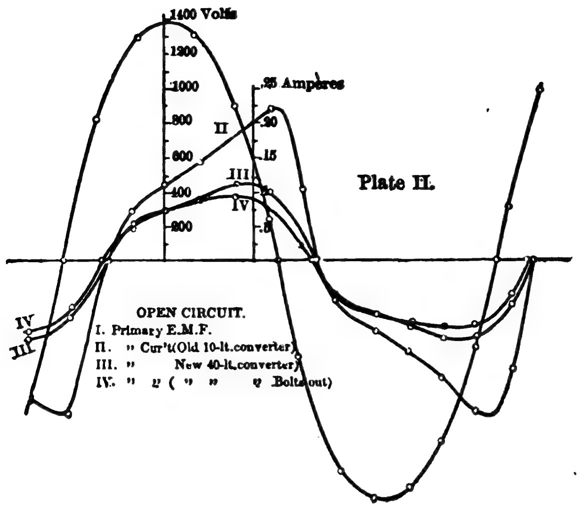
The form and extent of the open circuit curves show the loss due to hysteresis and the slight loss also due to the Foucault currents. The presence of Foucault currents is indicated by the fact that the maximum of the primary current wave does not occur simultaneously with the zero of primary E. M F., but a little before. It is found upon analysis of the primary current curve into its elements, hysteresis and Foucault currents, (see plate XIII.), that the Foucault current component occurs 120° in advance of the theoretical magnetization curve, and not 90° in advance, as has generally been assumed. Therefore, when superimposed upon the hysteresis curve, it introduces a component in advance and thereby decreases the lag of the primary current.

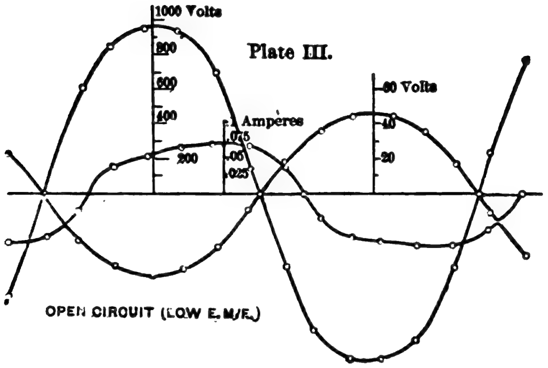
The primary current curve was again taken with the laminated plates loose and free to vibrate. The loss was about 10% less than in the former case (Plate II.) This is thought to be brought about by the decrease in the hysteresis loss, due to the increase of mechanical shock arising from the free vibration of the plates. The vibration was very perceptibly increased. The curve obtained is more regular in form indicating less hysteresis loss.

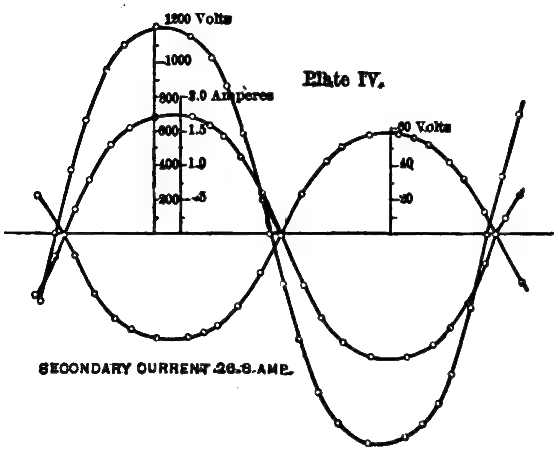
The lag of the primary current behind the primary E. M. F. is seen to be greatest when the secondary circuit was open and decreases as a non-inductive load is introduced into the secondary circuit. This tendency of the lag of the primary current to de-

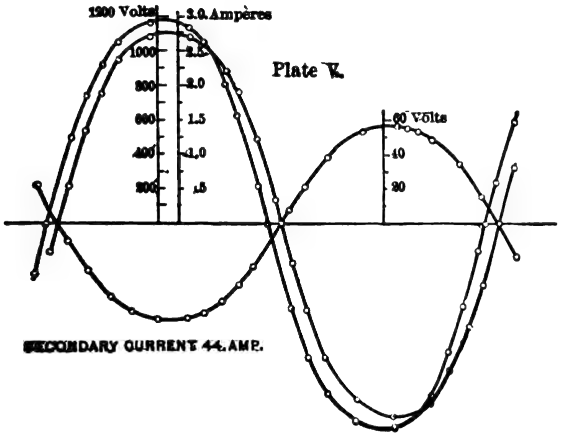
1. A paper read before the American Institute of Electrical Engineers, June 17, 1890.

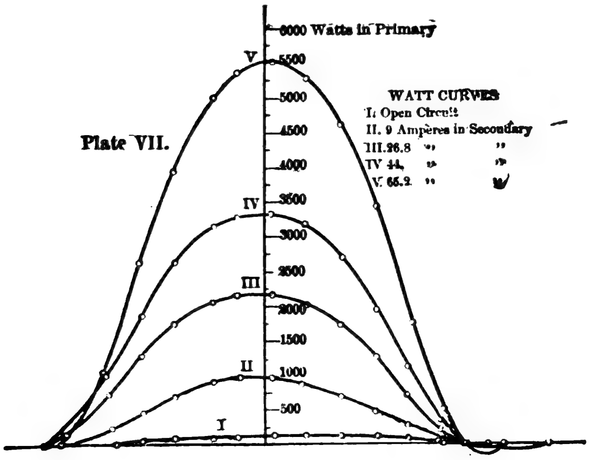


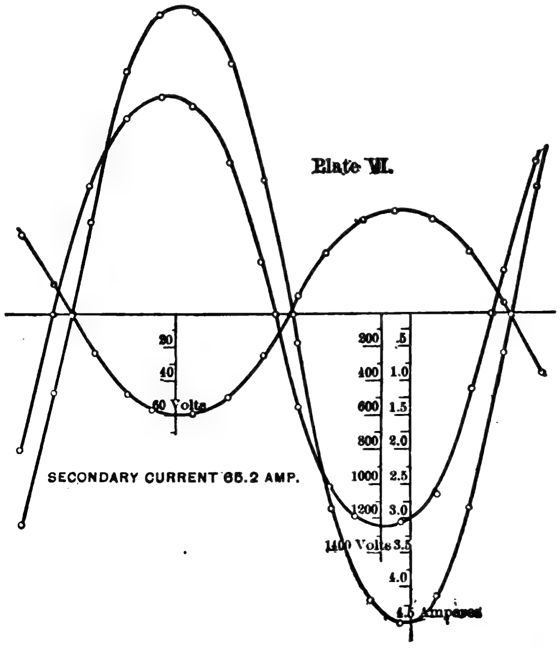












HUMPHREY AND POWELL ON TRANSFORMER EFFICIENCY.

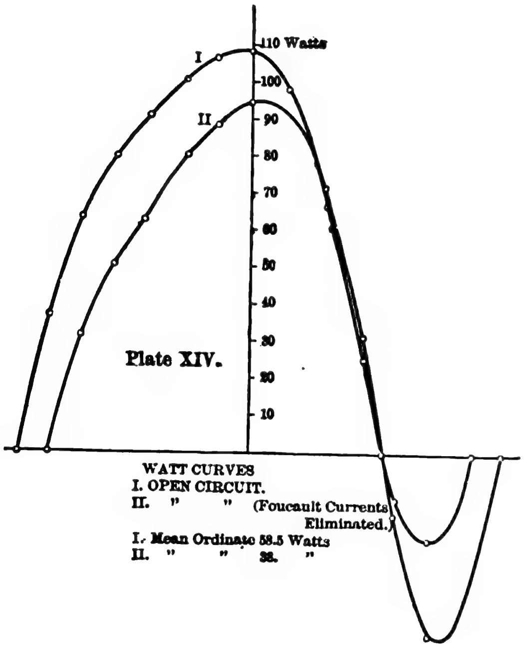
crease with increase of load, continues until the curve of primary current comes into unison with the curve of secondary E. M. F.

The secondary E. M. F. is in unison with the primary E. M. F. on open circuit and gradually falls behind as the load increases on the secondary. This is doubtless due to the leakage of lines of force arising from the enormous magnetizing forces at work in opposition to one another in the primary and secondary circuits.

When an inductive resistance is introduced into the secondary circuit, the lag of the primary current is greatly increased, as shown by the set of curves in Plate X. The inductive resistance used in this case was due to a small alternating current motor. The curve of secondary current was also taken and found to lag behind the secondary E. M. F. and to be in unison with the primary current. About 5.5 amperes flowed in the secondary and yet the lag of primary current is as great as on open circuit.

Plate XI shows the relation of primary current and primary E. M. F. when the secondary was closed through the secondary of a 20-light transformer whose primary remained open. The current curve shows a distinctive lag from the inductive resistance and is altered in form to a great extent.

The outside loop in Plate XII is the loop of total loss in hysteresis and Foucault currents, deduced from the open circuit curves in the following manner. The current which flows to maintain the counter E. M. F. of the transformer on open circuit obviously includes the losses due to Foucault currents and hysteresis. If then a megnetization curve whose maximum has been computed, be drawn in 90° behind the curve of primary E. M. F. and of the same form—since it is a function of the E. M. F.,—and a curve be plotted using ordinates of primary current as abscissae, and corresponding values of lines of force from the theoretical magnetization curve as ordinates, the outside loop in Plate XI is obtained.



The inside loop is the ordinary Ewing card of hysteresis loss found by carrying the iron slowly through a complete cycle of magnetization. The lines of force were computed from the "kick" on a ballistic galvanometer. This card has in it no Foucault current effects. If then we reverse the above method, and from the Ewing card and the magnetization curve deduce a primary current curve, we shall have a curve representing hysteresis loss for this iron. This was done, and it is of especial interest to note that the form of curve obtained in this manner is identical with the open circuit curve of the 10-light transformer in which Foucault currents were suppressed by the interposition of sheets of paper (see Curve III, Plate XIII.) Having then two curves plotted to the same scale, one representing total loss and the other hysteresis loss, if we subtract ordinates of the latter from corresponding ordinates of the former, a curve representing the component due to Foucault currents will be obtained (curve IV, Plate XIII.) It was in this manner that the analysis before referred to, was made. The position of the Foucault current component accounts for the round corners in the outside loop of Plate XII.

From Plate IX will be seen the watt curves for open circuit loss, one for 990 volts and the other for 740 volts. From the value of the mean ordinates it is seen that the loss varies strictly as the square of the impressed E. M. F.

In Plate II is plotted to the same scale the current which flowed on open circuit in the case of the 10-light transformer and the 40-light transformer.

Plates IV, V, and VI show the curves of primary E. M. F. and current and secondary E. M. F. for different loads, from which the watt curves of Plate VII. are computed by taking the product of corresponding ordinates of primary E. M. F. and current.

The efficiency curve shown in Plate VIII. is the ratio between the energy of the primary circuit as indicated by the mean ordinate of the watt curve, and the energy of the secondary circuit as expressed by the product of the $\sqrt{\text{mean}^2}$ readings for E. M. F. and the current. The coercive force is equal to .8 C. G. S.

These consideration go to show that the loss due to the reversal of polarity of the iron, which perhaps must always be present, may be reduced almost indefinitely by a proper study of the magnetic properties of the iron used.

The watt curves in Plate XIV show the relation between the total loss on open circuit and the loss if Foucault currents were eliminated.

ELECTRIC ADHESION DEMONSTRATED BEFORE THE RAILWAY MASTER MECHANICS.

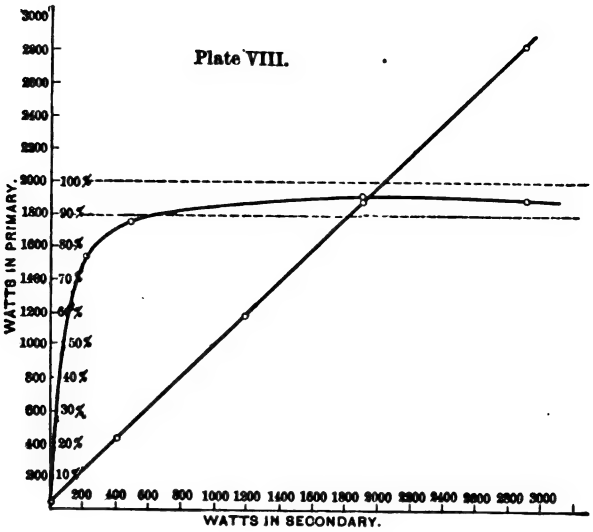
At the recent convention of the American Railway Master Mechanics' Association, held at the Hygeia Hotel, Old Point Comfort, Va., there was exhibited a small working model illustrating the operation of the Ries electric traction increasing system as applied to steam locomotives. This exhibit attracted considerable attention and was the occasion of no little astonishment among those of the master mechanics who hitherto believed that there was nothing to equal sand as a traction increaser. The passage of a low tension quantity current between the driving wheels and rails enabled the locomotive to readily ascend grades varying from 20 to 45 per cent. in steepness, whereas without this current the revolving driving wheels were unable to make any headway on grades considerably less severe than the one first mentioned. The pulling capacity of the locomotive on a level track was very greatly increased by the passage of the current, and it was also shown, much to the surprise of the expert master mechanics, that the increased tractive adhesion resulting therefrom was not diminished when the rails were wet or coated with oil. The remarkable efficiency of the traction increasing current as a braking agent was likewise exemplified by its promptness in arresting the momentum of the locomotive on a steep down grade while sliding rapidly from the top toward the bottom of the latter.

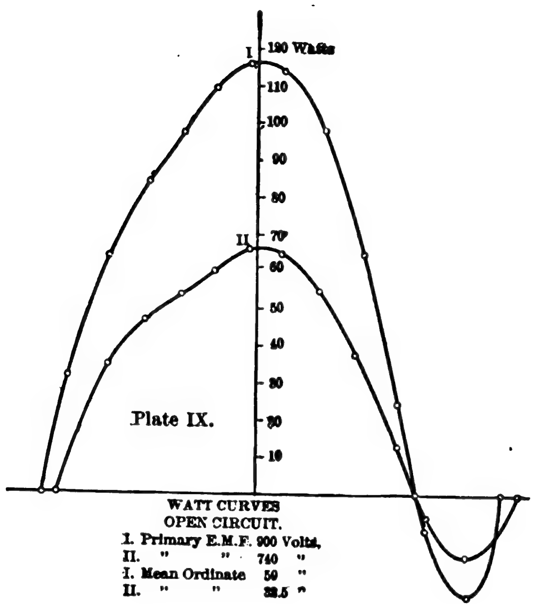
The performance of the apparatus was a revelation to those who witnessed it, and elicited much favorable comment. Drawings showing the application of the system to full sized locomotives were exhibited, and were critically examined. The apparatus was in charge of Mr. Elias E. Ries, who was kept busy in explaining its operation. The system has already been successfully applied to railway locomotives, and further experiments in this direction are now being made.

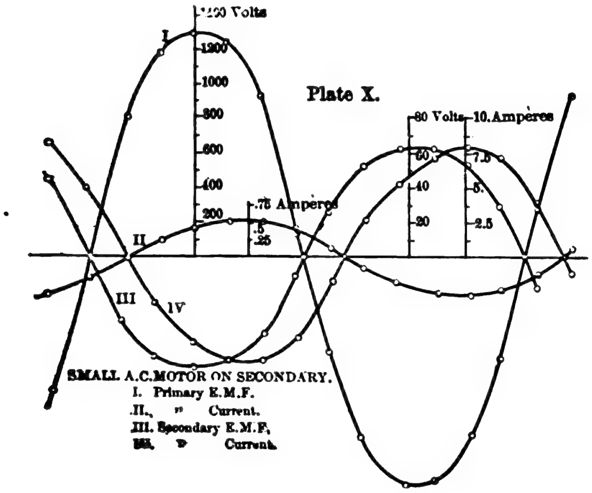
It is claimed that by means of this system the traction power of locomotives may be increased fully 25 per cent. over what it is at present; that engines thus equipped will be enabled to draw longer and heavier trains, to mount steeper grades and to make better time; that the wear and tear upon the wheels and rails due to slipping and the use of sand is avoided; that light locomotives having sufficient steaming power can do the work of heavier engines, thus avoiding the increased strain upon rails, road-bed, bridges, etc., and in many instances rendering the reconstruction of the latter for heavier traffic unnecessary; that the condition of the weather cannot affect the schedule time by reason of lessened tractive adhesion, as at present; that trains may be brought under headway and stopped more quickly by reason of the absence of slipping of the drivers due to the action of the current; that the consumption of fuel for generating the traction current is considerably less than the saving in fuel effected by the absence of slipping alone; that in many cases the running of passenger and freight trains in separate sections may be avoided, as well as the expense and delays to traffic occasioned thereby; that a passenger or freight train drawn by a locomotive equipped with this system is safer and under more perfect control on steep grades, and, finally, that the earning capacity of a line of road having its engines so equipped can be very largely increased.

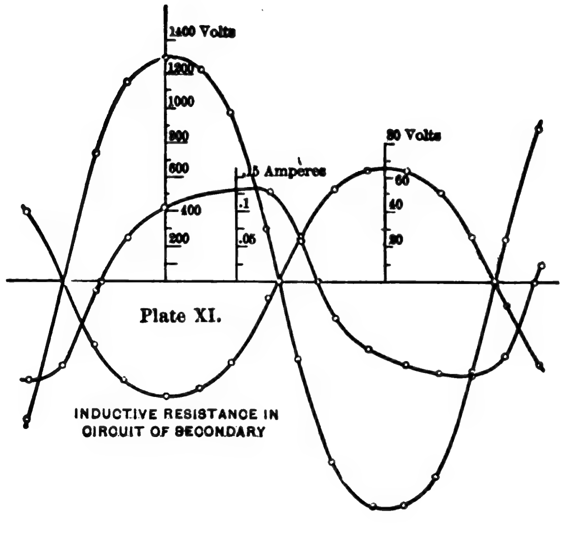
FIRE ALARMS IN NEW YORK CITY.

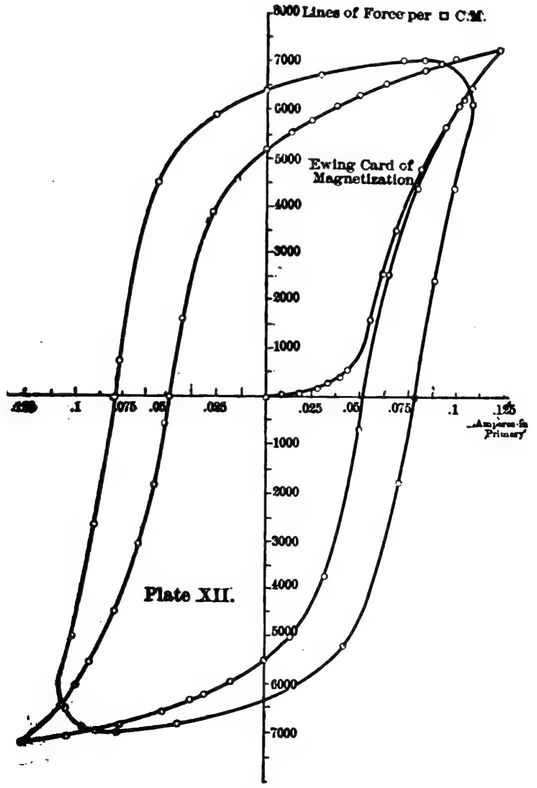
New York city is to have a new system of fire signals. Chief Hugh Bonner has devoted nearly all his spare time for more than a year to the new code, and J. Elliot Smith, the Superintendent of Telegraph at Fire Headquarters, has aided him as electrical expert. The new code is necessary because the city has outgrown the old signal box, and districts which were important have become unimportant, and vice versa. The aim of its compiler has been so to cover the city with signals that the number 999 should not be passed or reached, as beyond that number four figures would have to be employed, which would not only be troublesome but perilous. When it becomes necessary to have more than 999 signal stations a new system—probably one of districting—will have to be devised.



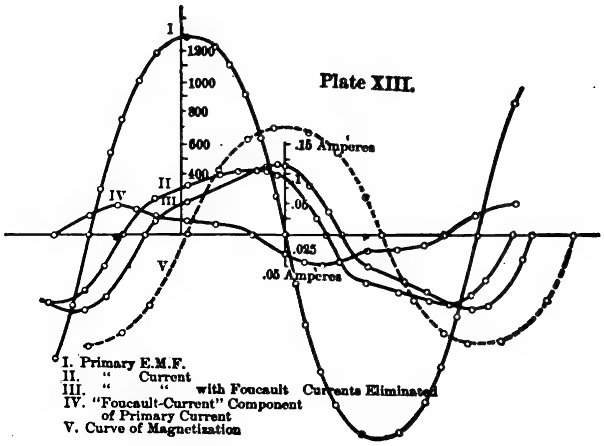








Ordinates should be multiplied by 0. 64.



HUMPHREY AND POWELL ON TRANSFORMER EFFICIENCY.

CORRECT TIME—HOW SHALL WE MAINTAIN IT?[1]

BY H. S. PRITCHETT,

Sup. Time Service and Watch Inspection, Wabash Railroad.

The problem of furnishing and maintaining correct time has become within the past ten years relatively much more important than it was during the earlier history of railroading in the United States. Under the present system of train dispatching, requiring the movement of numerous trains of different classes over a single line of track, as is generally the case on our American roads, an exact and uniform time system is a necessary part of the safe and efficient operation of any railway. It may be stated here that a long step in the right direction was taken when the plan of uniform time over large areas, now in use, was adopted.

It may be stated at the outset that the matter of time service as it is involved in the practical operation of railroads will naturally come under the following heads:

1. The distribution of time signals to all stations.

2. The regulation of certain time pieces at division points, train dispatchers' offices and other important points, to serve as secondary time standards during the 24 hours intervening between the sending of time signals.

3. Even after providing for uniform and exact time in this manner, it is still desirable to provide by a judicious system of inspection that the time so furnished is actually kept in the pockets of the employees engaged in the movement of trains.

Assuming that the time can be thus obtained from some satisfactory source, the problem in which the telegraph department of the railroad is immediately interested, is the distribution of time signals. On our American railroads two plans of giving time to all offices have been in use. It may be stated in passing, that in this matter of time service our American roads are far beyond those of England or the Continent.

The first of the methods alluded to consists in obtaining time from some observatory by a central office, and then distributing by hand to all stations in accordance with an agreed programme. The other consists in an automatic service directly from the observatory to all stations. As nearly as can be ascertained, about 115,000 of the 160,000 miles of railway of the United States are being furnished with an automatic distribution of time signals direct from observatories. The advantages in favor of a direct automatic service are very great, and experience show that the value of such a service increases with time. These advantages may be stated as follows:

1. The automatic clock-beats direct from an observatory give the time with a precision which can be gained in no other way, and it is astonishing to see how quickly employees see and appreciate this. Many of the employees in the railway service now carry watches of high grade and watch the time with the utmost care. A time standard which varies, even by so little as two or three seconds, first one way and then another, will quickly lose their respect and attention. Experience has shown in a very conclusive way that nothing conduces more to the maintenance of correct and exact habits in employees than the furnishing of an absolutely exact time standard.

2. Again the automatic beats, if properly put on the wires, coming as they do with regular, rythmical contacts, can be transmitted in bad states of the wires when nothing else can.

At times there have been objections to the automatic observatory service. I believe it to be essential in any programme of time signals that the actual clock signals should be preceded by some warning, and that the plan of sending should be as simple as it can be made, and that the time consumed be as short as is consistent with giving several opportunities for identifying the minute and second.

The following programme of sending has been in use at the observatory of Washington University, St. Louis, for some years. It is largely the result of the practical experience of Mr. Hammond and Mr. Kinsman, and combines, I believe, all the qualities of simplicity and brevity mentioned above.

The entire programme occupies three minutes. The first minute is taken up in calling the word "Time." This necessitates, of course, the presence of an operator at the observatory and in fact makes the observatory one of the offices of the company, and the time service a part of the regular business of the railroad.

After calling "Time" for a minute the automatic signals are begun by the standard clock at two minutes before the hour, sending double beats each second for 50 seconds. The circuit is then opened for 10 seconds, and at one minute before the hour single beats begin and continue for 50 seconds, when again the circuit is opened for 10 seconds, followed at the exact hour by a single beat which is purposely prolonged to nearly a second in length to make sure of synchronizing clocks along the line of the road.

The apparatus in use in putting signals upon the wires is of an original design and has been found to work well in the transmission of signals over long distances. It consists of a platinum arc attached to the end of a second's pendulum clock, which swings through a narrow mercury contact. As long as the mercury is in contact with the platinum the circuit is closed. The circuit is broken by a small opening in the wheels of the arc. This opening is adjustable. The special advantage of the device is that the signals so produced are not instantaneous contacts, but hold the circuit closed an appreciable fraction of a second, so that there is no difficulty in repeating in this way over long lines.

Under such a system we find it entirely practicable to distribute observatory time signals to all stations with all the certainty that can be desired. Operators at all stations where time is received are required to be on hand and acknowledge the receipt of time by signing their office call. These signatures are recorded on a form by the train dispatcher of each division and by him are turned in to the superintendent of telegraphs at the end of each week. It requires only a glance at these to see how each man has looked out for time.

This regulation of requiring operators to be on hand to set clocks and acknowledge the receipt of time has proven to be of excellent practical value not only in creating and maintaining a careful attention to the matter of correct time, but also indirectly in the inculcation of exact and accurate habits. Furthermore it is often convenient to have each man at the key at a certain hour of the day.

The question of the proper hour at which time should be sent has been discussed for some years at various railway gatherings. Some years ago the General Time Convention recommended the hour of 4 o'clock, P. M. as that best suited for the distribution of railway signals. In accordance with that recommendation we began at St. Louis the distribution of time signals at that hour to a number of roads. After a trial of one or two years, however, nearly all these roads have gone back to the hour of 10 o'clock A. M. as being most convenient and best suited to railway purposes.

There are good reasons in favor of both the morning and afternoon hour, but on the whole I am of the opinion that 10 A. M. is as good an hour as can be selected for this purpose.

The consideration of the subject has so far been devoted entirely to the consideration of a practical system of distribution of time signals. It is necessary, however, in any system of railroad time service to provide at certain important points, such as train dispatchers' offices, fixed time-pieces to be regulated by the time signals, and which shall serve as secondary time standards during the 24 hours intervening between the sending of time.

The regulation and means of correcting these secondary standards would necessarily form a part of any practical time service which should be adopted. In the observatories the standard clocks are not corrected at all, but are allowed to accumulate their errors from year to year, the correct time being deduced at any moment from the known error and rate. In railroad service it is necessary to keep all time pieces within a very few seconds of exact time. The problem is to do this efficiently and practically without introducing too complicated apparatus.

The plan in use on most of our American roads is to have a clock of moderately good make, which is set right from the time-signals daily by the operator in charge. Such a time-piece should be capable of an easy and accurate setting of the hands. For this reason a chronometer is a very poor investment for a railroad company, since it is not only high priced but very difficult to set, and requires the services of a practical watch maker to look after it, in order to keep close to correct time.

The objection to this plan of regulating important time-pieces is that, unless orders are strictly enforced, operators allow a considerable error to accumulate before setting the clock, and then pull it up all at once like a run-away horse, the effect of which is to make employés lose confidence in the whole system.

For some years past various synchronizing devices have been in use on a number of roads for the purpose of setting clocks automatically by the time signals. The best known of these are the Self-winding Clock Company's synchronized clock and the Gardner synchronizer, which is now also owned by the Self-winding Clock Company. The former of these is wound by a small motor each hour, the power being furnished by two cells of Leclanché battery. Beside this self-winding attachment the clock has also a synchronizing device for setting the minute and second hands. The Gardner device, on the other hand, is applied to an ordinary clock, and the clock is dependent on the electricity for a correction only.

The problem of synchronizing a series of clocks by either of these devices is entirely easy and simple. In the system of time-signals which I have described the circuit is opened for 10 seconds just preceding the exact hour. During this interval the operator in charge of the clock to be synchronized needs simply to turn a switch, and the single beat coming at the exact hour sets the hands. This beat is purposely made nearly a second in length to insure a firm and decided closing of the circuit.

On the Wabash Railroad we have a synchronized clock at all train despatchers' offices. A careful record is kept daily by the operator in charge and turned in to me at the end of each month. It seldom happens that a clock fails to set, and they are rarely

1. Abstract of a paper read before the 9th Annual Meeting of the Association of Railway Telegraph Superintendents, Niagara Falls, June 19, 1890.

more than five seconds off from correct time at the end of twenty hours' run.

In spite of all this, however, there are many things which go far to neutralize the benefits to be derived in railroad work from the easy and accurate setting. We have for three years given these devices a very extensive trial, using both the self-winding clock and the Gardner device.

Both of these devices are excellent in their way, and can be used with perfect success in a large city where a considerable plant is maintained, and where a skilled man is on hand to remedy any trouble that may arise, either in the motor part of the clock or in the synchronizer. But when one comes to place these clocks at isolated stations scattered along several thousand miles of a great railway system the problem is of an entirely different sort.

A railway furnished with good ordinary clocks at important points can, by careful instructions to despatchers, keep these clocks within the limit of error attained by the synchronized clocks, and if the clocks are carefully rated they will not need to be set more frequently than two or three times a week, but their errors in seconds should be posted on a slip prepared for that purpose each day. If properly furnished with accurate time-signals the synchronized clocks are, in my opinion, of secondary importance in the practical operation of a railway time service. Even after furnishing exact time to all stations, and providing clocks at important points to serve as secondary standards, experience has shown that it is still necessary to follow this up and see that the time so provided is actually kept in the watches of employees that are engaged in the movement of trains.

LIGHTNING CONDUCTORS FROM A MODERN POINT OF VIEW [1]

BY PROF. OLIVER J. LODGE.

A LIGHTNING conductor used to be regarded as a conduit or pipe for conveying electricity from a cloud to the ground. The idea was that a certain quantity of electricity had to get to the ground somehow; that if an easy channel were opened for it the journey could be taken quietly and safely, but that if obstruction were opposed to it violence and damage would result. This being the notion of what was required, a stout copper rod, a wide-branching and deep-reaching system of roots to disperse the charge as fast as the rod conveyed it down, and a supplement of sharp points at a good elevation to tempt the discharge into this attractive thoroughfare, were the natural guarantees of complete security for everything overshadowed by it. Carrying out the rain-water-pipe analogue, it was natural also to urge that all masses of metal about the building should be connected to the conductor, so as to be electrically drained to earth by it, and it was also natural to insist on very carefully executed joints, and on a system of testing resistance of conductor and "earth" so as to keep it as low as possible. If ever the resistance rose to 100 ohms it was to be considered dangerous.

The problem thus seemed an easy one, needing nothing but good workmanship and common sense to make accidents impossible. Accordingly, when, in spite of all precautions, accidents still occurred, when it was found that from the best-constructed conductors flashes were apt to spit off in a senseless manner to gun-barrels and bell ropes and wire fences and water butts, it was the custom to more or less ridicule and condemn either the proprietor of the conductor, or its erector, or both; and to hint that if only something different had been done—say, for instance, if glass insulators had not been used, or if the rod had not been stapled too tightly into the wall, or if the rope had not been made of stranded wires, or if copper had been used instead of iron, or if the finials had been more sharply pointed, or if the earth-plate had been more deeply buried, or if the rainfall had not been so small, or if the testing of the conductor for resistance had been more recent, or if the wall to which the rod was fixed had been kept wet, or &c., &c.,—then the damage would not have happened. Every one of these excuses has been appealed to as an explanation of a failure; but because the easiest thing to abuse has always been the buried earth connection, that has come in for the most frequent blame, and has been held responsible for every accident not otherwise explicable.

All this is now changing or changed. Attention is now directed, not so much to the opposing charges in cloud and earth, but to the great store of energy in the strained dielectric between. It is recognized that all this volume of energy has somehow to be dissipated, and that to do it suddenly may be by no means the safest way. Given a store of chemical energy in an illicit nitroglycerine factory, it could be dissipated in an instant by the blow of a hammer, but a sane person would prefer to cart it away piecemeal and set it on fire in a more leisurely and less impulsive manner. So also with the electrical energy beneath a thundercloud. A rod of copper an inch or a foot thick may be too heroic a method of dealing with it; for we must remember that an electric discharge, like the recoil of a spring or the swing of a pendulum, is very apt to overshoot itself, and is by no means likely to exhaust itself in a single swing. The hastily discharged cloud, at first, suppose, positive, over-discharges itself and becomes negative; this again discharges and over-discharges till it is positive as at first, and so on, with gradually diminishing amplitude of swing, all executed in an extraordinarily minute fraction of a second, but with a vigor and wave-producing energy which are astonishing. For these great electrical surgings, occurring in a medium endowed with the properties of the ether, are not limited to the rod or ostensible conduit; the disturbance spreads in all directions with the speed of light, and every conducting body in the neighborhood, whether joined to the conductor or not, experiences induced electrical surgings to what may easily be a dangerous extent. For not only is there imminent danger of flashes spitting off from such bodies for no obvious reason—splashes which, on the drain-pipe theory, are absolutely incredible—flashes sometimes from a perfectly insulated, sometimes from a perfectly earthed, piece of metal; but, besides this, remember that near any considerable assemblage of modern dwellings there exists an extensive metallic ramification in the gas-pipes, that these are in places eminently fusible, and that the substance they contain is readily combustible.

On the drain-pipe theory, the gas-pipes, being perfectly earthed would be regarded as entirely safe so long as they were able to convey the current flowing along them without melting; but, on the modern theory, gas-pipes constitute a widely spreading system of conductors able to propagate disturbance underground to considerable distances, and very liable to have some weak and inflammable spot at places where they are crossed by bell wires or water-pipes or any other metallic ramification.

Above ground we have electrical waves transmitted by the ether, and exciting surgings throughout a neighborhood by inductive resonance. Below ground we have electrical pulses conveyed along conductors, leaking to earth as they go, but retaining energy sufficient to ignite gas, whenever conditions are favorable, at considerable distances.

The problem of protection, therefore, ceases to be an easy one, and violent flashes are to be dreaded, no matter how good the conducting path open to them. In fact, the very ease of the conducting path, by prolonging the period of dissipation of energy, tends to assist the violence of the dangerous oscillations. The drain-pipe theory, and the practical aphorisms to which it has given rise, would serve well enough if lightning were a fairly long-continued current of millions of amperes urged by a few hundred volts, or if there were no such thing as electromagnetic inertia; but, seeing that the inverse proportion between amperes and volts better corresponds to fact, and seeing that the existence of electromagnetic inertia is emphasized by multitudes of familiar experiments, the drain-pipe theory breaks down hopelessly, and only a few of its aphorisms manage to survive it.

What, then, are we to set up in place of this shattered idol? First of all we can recognise what was virtually suggested by Clerk Maxwell, that the inside of any given enclosure, such as a powder magazine or dynamite factory, can, if desired, be absolutely protected from internal sparking by enclosing it in a metallic cage or sheath, through which no conductor of any kind is allowed to pass without being thoroughly connected to it. The clear recognition of the exact, and not approximate, truth of this statement is a decided step in advance, and ought to be satisfactory to those who have to superintend the practical protection of places sufficiently dangerous, or otherwise important, to make the aiming at absolute security worth while. Similarly, for wire-covered ocean cables absolute protection is possible. But not for ordinary buildings, any more than for ordinary land telegraph offices, is such a plan likely to be adopted in its entirety. Some approximation to the cage system can be applied to ordinary buildings in the form of wires along all its prominent portions; and such a plan I have suggested, and I understand it is being carried out, for the entrance towers and part of the main body of the present Edinburgh Electrical Exhibition, Mr. A. R. Bennett having asked me to recommend a plan to the Committee as a sort of exhibit. For chimneys a set of four galvanized iron wires, joined by hoops at occasional intervals, and each provided with a fair earth, seems a satisfactory method; but it is to be noted that a column of hot air constitutes a surprisingly easy path, and that it is well to intercept a flash on its way down the gases of a chimney by a copper hoop or pair of hoops over its mouth. Mr. Goolden tells me that he has just applied this method to a new chimney at his works in the Harrow Road. For ordinary houses, a wire down each corner and along the gables is as much as can be expected. At many places even this will not be done; a couple of vertical wires from the highest chimney stacks on opposite sides must be held better than nothing or than only one.

Earths will be made, but probably they will be simple ones, entailing no great expense. A deep, damp hole for each conductor, with the wire led into it and twisted round an old harrow or a load of coke, may be held sufficient. And as to terminals, rudely sharpened projections, as numerous as is liked, may be arranged along ridges and chimney stacks; but I have at present no great faith in the effective discharging power of a few points, and should not be disposed to urge any considerable expense in erecting or maintaining them. Crowns of points on chimneys and

1. *Industries.*

steeples are certainly desirable, to ward off, as far as they can, the chance of a discharge, but a multitude of rude iron ones will be more effective than a few highly sharpened platinum cones. I find that points do not discharge much till they begin to fizz and audibly spit; and when the tension is high enough for this, blunt and rough terminals are nearly as efficient as the finest needle points. The latter, indeed, begin to act at comparatively low potentials, but the amount of electricity they can get rid of at such potentials is surprisingly trivial, and of no moment whatever when dealing with a thundercloud.

But the main change I look for in the direction of cheapness and greater universality of protection is in the size and material of the conducting rod itself. No longer will it be thought necessary to use a great thick conductor of inappreciable resistance; it will be perceived that very moderate thickness suffices to prevent fusion by simple current strength, and that excessive conducting power is useless.

In the days when the laws of common "divided circuits" were supposed to govern these matters, the lightning rod had to be of highly conducting copper, and of such dimensions that no other path to earth could hope to compete against it. But now it is known that low resistance is no particular advantage; it is not a question of resistance. The path of a flash is a question of impedance, and the impedance of a conductor to these sudden rushes depends very little on cross-section and scarcely at all on material. A thin iron wire is nearly as good as a thick copper rod, and its extra resistance has actually an advantage in this respect, that it dissipates some of the energy, and tends to damp out the vibrations sooner. Owing to this cause a side flash from a thin iron wire is actually less likely to occur than from a stout copper rod.

The only limit is reached when the heat generated by the current fuses the wire, or runs the risk of fusing it. But in so far as oscillations are prevented, the mean square of current strength on which its heating power depends is diminished. Accordingly, a fairly thick iron wire runs no great risk of being melted. Its outer skin, may, indeed, be considerably heated, for these sudden currents keep entirely to the outer skin, penetrating only a fraction of a millimetre into iron, and they make this skin intensely hot. But the central core keeps cool until conduction has time to act; and, consequently, unless the wire is so thin as to be bodily deflagrated by the discharge, its continuity is not likely to be interrupted. Thickness of wire is thus more needed in order to resist ordinary deterioration by chemical processes of the atmosphere than for any other reason.

But the liability to intense heating of the outer skin should not be forgotten, and care should be taken not to take the wire past readily inflammable substances for that reason. For instance, it would be madness to depend on Harris's notion that a lightning conductor through a barrel of gunpowder was perfectly safe, especially if said conductor were an iron wire or rod.

In the old days a lightning conductor of one or two hundred ohms resistance was considered dangerously obstructive, but the impedance really offered by the best conductor that ever was made to these sudden currents is much more like 1,000 ohms. A column of copper a foot thick may easily offer this obstruction, and the resistance of any reasonably good earth connection becomes negligible by comparison. A mere wire of copper or iron has an impedance not greatly more than a thick rod, and the difference between the impedance of copper and iron is not worth noticing.

But although, in respect of obstructing a flash, copper and iron and all other metals are on an approximate equality, it is far otherwise with their resistances, on which their powers of dissipating energy into heat depend. It is generally supposed that iron resists seven times more than copper of equal section, and so it does steady currents, but to these sudden flashes its resistance is often 100 times as great as copper, by reason of its magnetic properties. This statement is quite reconcilable with the previous statement, that in the matter of total obstruction there is very little to choose between them; the apparent paradox is explicable by the knowledge that rapidly varying currents are conveyed by the outer skin only of their conductor, and that the outer skin available in the case of magnetic metals is much thinner than in the case of non-magnetic.

Questions about shape of cross-section are rather barren. Thin tape is electrically better than round rod, but better than either is a bundle of detached and well-separated wires—for instance, a set of four, one down each cardinal point of a chimney; but it is easy to over-estimate the advantage of large surface as opposed to solid contents of a conductor. The problem is not a purely electrical one—it is rather mixed. The central portion or core of a solid rod is electrically neutral, but chemically and thermally and mechanically it may be very efficient. It confers permanence and strength; and the more electrically neutral it is, the less likely is it to be melted. Its skin may be gradually rusted and dissolved off, or it may be suddenly blistered off by a flash; but the tenacity of the cool and and solid interior holds the thing together, and enables it to withstand many flashes more. Very thin ribbon or multiple wire, though electrically meritorious, is deficient in these commonplace advantages.

There were two functions attributed to high conducting power in the old days—first the overpowering of all other paths to earth second, the avoidance of destruction by heat. The first we have seen to be fallacious; on the second a few more explanations can be made. In so far as fusion by simple current strength is the thing dreaded, it must be noticed that a good conductor has no great advantage over a bad conductor. It is a thing known to junior classes that when a given current has to be conveyed less heat is developed in a good conductor, but that when an electromotive force is the given magnitude less heat is developed in a bad conductor. The lightning problem is neither of these, but it has quite as much relationship to the second as to the first. There is a given store of energy to be got rid of, and accordingly the heat ultimately generated is a fixed quantity. But the rise of temperature caused by that heat will be less in proportion as the production of it is slow; and though by sudden discharge a quantity of the energy can be made to take the radiant form, and spread itself a great distance before final conversion into heat, instead of concentrating itself on the conductor, yet this cannot be thought an advantage. For, just as in the old days a lightning rod was expected to protect the neighborhood at its own expense by conveying the whole of a given charge to earth, so now it must be expected to concentrate energy as far as possible on itself, and reduce it to a quiet thermal form at once, instead of, by defect of resistance and over-violent radiation, insisting on every other metallic mass in its neighborhood taking part in the dissipation of energy.

The fact that an iron wire, such as No. 5 or even No. 8 B. W. G., is electrically sufficient for all ordinary flashes, and that resistance is not a thing to be objected to, renders a reasonable amount of protection for a dwelling-house much cheaper than it was when a half-inch copper rod or tape was thought necessary.

A recognition of all the dangers to which a struck neighborhood is liable doubtless prevents our feeling of confidence from being absolute in any simple system of dwelling-house protection; but at the same time an amount of protection superior to what has been in reality supplied in the past is attainable now at a far less outlay; while, for an expenditure comparable in amount to that at present bestowed, but quite otherwise distributed, a very adequate system of conductors can be erected.

Only one difficulty do I see. In coal-burning towns galvanized iron wire is, I fear, not very durable, and renewal expenditure is always unpleasant. It is quite possible that some alloy or coating able to avoid this objection will be forthcoming, now that inventors may know that the problem is a chemical one and that high conductivity is unnecessary.

ON THE TREATMENT OF ORES BY THE ELECTROLYTIC METHOD.

A well-known writer says in his work on metallurgy and in reference to the electrolytic treatment of ores: "During the past forty years many attempts have been made to extract metals from their ores by electrolysis, and many ingenious processes have been devised, but few of these, so far as we are aware, have proved successful. Some of the earlier investigations of Bunsen, Sainte-Claire Deville, and Becquerel are of special importance as indicating the general principles upon which such electrolytic operations may be conducted; there is little doubt, however, that much has yet to be done before the separation of the metals from their ores will attain the position of a really practical branch of electro-chemistry. We have noticed in the cases of copper refining by the wet way, that many attempts were made in this direction long before a commercially successful application of the electrolytic method was arrived at, and we still hope and believe that electricity will be practically employed in extracting metals from their ores; indeed, some trials which we have recently made in this connection are at least of a very hopeful character." This paragraph could now well be eliminated from his work. Electrical engineering firms for the past three years have given this branch of the profession great attention, and with the result that their efforts in constructing dynamos especially adapted for this work have been successful. The United Edison Company, with their unusual facilities for the manufacturing of generators, promptly exploited this field, and are now turning out dynamos to develop any amount of current requisite for the capacity of the works treating the ores.

Many mine owners and operators of existing plants treating ores in the old method have, from time to time, been considerably exercised in their minds in reading and hearing reports and marvellous statements about the out-put of the establishments already provided with plants for treating copper ore electrolytically. These points are:—

1. The pureness of copper deposited.
2. The recovery of the gold and silver obtained by no other method.
3. The cheapness of production.
4. The ready sale of the product.

These statements are so far true, but the mine owners, on investigating the matter, have had great obstacles thrown in their way, getting no information as to the construction of the plants, and being told that the method is altogether conducted in a secret

manner. This consequently has dampened their ardor and they have returned to their old system of conducting their operations. But it may be at once stated that there is no real secret process. Owners of electrolytic plants have only adopted the ordinary wise and business caution when they have a good thing, of keeping it, as far as possible, to themselves. The United Edison Company, with a thorough knowledge of the whole system, now inform us that they will contract with parties to furnish them with a complete plant, including motive power and generators, baths, pumps, and with all the necessary information for conducting, with financial success, the operations of treating any ores by the electrolytic method.

CORRESPONDENCE.

BOSTON.

Marriage of Mr. H. C. Spaulding.—Anniversary of Boston Electric Club.

THE many friends of Mr. Hallon Curtis Spaulding, general manager of the Thomson-Houston Motor Company, are congratulating him upon the occasion of his marriage to Miss Lucille Brisbine, of Nashua, N. H. The ceremony took place on Tuesday afternoon, the 24th inst., after which Mr. and Mrs. Spaulding departed for a month's trip in the west. The ushers were Mr. G. W. Mansfield, T. W. Sprague, Frank Codman, H. C. Glover, F. L. Locke, of Boston, and Dixi Crosby, of New York, with Mr. H. B. Prindle, as chief usher. The ceremony was at the Church of the Good Shepherd, Rev. W. H. Moreland, rector, officiating. The music was very elaborate, being sung by a vested choir of 40 boys. The church was decorated, and filled with admiring friends. Fred. B. Lovejoy, of Boston, was best man, Miss Sophia Walton, of New York, maid of honor, and six young ladies served as bridemaids. Mr. Spaulding enjoys the good wishes of a host of friends among the electrical fraternity.

THE Boston Electric Club celebrated its third anniversary by a delightful outing on Saturday last, to the Nanepashemet House, on Marblehead Neck. Members and guests took the 12.30 train to Marblehead, reaching the Nanepashemet House by barges about 2 o'clock, where a sumptuous fish dinner was served at once.

President Cram presided at the table, and after dinner said a few words congratulating the members upon the continued success of the club. His remarks were quite brief, however, as members were more anxious to be out enjoying themselves in the open air than to hear speeches, however interesting. A photograph of the group was taken on the balcony of the hotel, and a subsequent view of this picture impresses one with the idea of how many stalwart, handsome men there are in the club; not a few of them, moreover, evidently being keen sportsmen. A unique game of base ball then attracted attention, good, bad and indifferent players all alike vieing with one another to emulate a Kelly or a Ward. Without mentioning any names we may say that there were a number of the members who showed their prowess in the game, and "home runs" were of frequent occurrence, the happy hitter being rewarded by getting his arm nearly shaken off by his associates. At the close the score stood 24 to 16, and the game was gracefully awarded to the winners with a rousing cheer. The party left for Boston at 6 o'clock, and indulged in songs and speeches, and made things merry till Boston was reached, when everyone agreed that a most enjoyable time had been spent.

THE investigation into the charges of improper influence alleged to have been employed at the legislature to secure the passage of elevated railroad bills is concluded. The committee will probably report early next week and the session will then be brought to a speedy close.

BOSTON, June 28, 1890.

PITTSBURG.

Printing by Electric Motor.—The Allegheny City Municipal Plant—Electric Railway Work.

The Western Democrat is the first newspaper in the state of West Virginia printed by electric power. The first issue brought out with the aid of the electric motor appeared on the morning of June 23d.

The citizens of Allegheny have now decided not to start with the operation of their electric light plant until July 18. This change has been made for the reason that on that day the city will hold its semi-centennial celebration, and it is proposed to have the electric lights play an important part in the festivities. Arrangements have been made to light the entire plant on the evening of the celebration, and in order to make the effect more brilliant, all the incandescent and arc lamps will be covered with colored globes of various hues and shades.

The Wilkins and Braddock street railway company and the Pittsburg, Braddock and Turtle Creek street railway company received their charters at Harrisburg, Pa., a few days ago; capital, $36,000.

A large corps of workmen were started last week on the lines of the Pittsburg, Allegheny and Manchester railroad company for the purpose of putting down new tracks. This is the road which, at a meeting held not long ago decided to change its motive power and adopt an electric street car system. The councils of Allegheny city passed an ordinance granting the company the right to do so, provided the company would begin making the change before the first of July. It was in conformity with this ordinance that the workmen were set to work last week. The P., A. and M. passenger railway company controls the Western avenue line, the Union line, the Rebecca street line, the Troy Hill line and the Allegheny Transverse line, running 100 cars every day. The contract for the electric equipment of the road has not been let yet, but a decision will be made in this direction very shortly.

PITTSBURG, June 27, 1890.

CHICAGO.

Bids for City Underground Cable.—The People's Electric Light Co.—The Cicero and Proviso Street Railway Co.

BIDS were opened last week by Controller Onahan for thirty miles of electric light cable for underground use. It is understood that the contract for the same will be placed with the Cobb Vulcanite Wire Co., of Wilmington, Delaware, who were the lowest bidders.

The backers of the People's Electric Light Company are demanding that the city carry out the provisions of the contract entered into between that company and the old Town of Lake for the maintenance of 200 arc electric lights at $12.50 a lamp per month, and the city will probably refuse to do so on the ground that one corporation can not bind a succeeding similar corporation to a contract. The contract has been submitted to the city officers. It is dated July 13 of last year, and is specific as to lamps, their location, the rate, and the time of the contract, a period of four years.

The Cicero and Proviso Street Railway Company has applied to the public works department for a permit to lay tracks for an electric street car line in that portion of the city formerly a portion of Cicero. The franchise of the company is dated April 18, 1889, and the promoters say it was pending several months before that. A power-house has been erected, the company says, and they wish a permit to go to work on the streets named in the franchise: Madison, from Fortieth street to Harlem avenue; Lake and Forty-eighth streets to Harlem avenue; Harlem avenue and Forty-eighth street, from Lake to Madison. No permit has yet been obtained from the Cicero authorities. The law department is looking over the ordinance.

CHICAGO, June 27, 1890.

SOCIETY AND CLUB NOTES.

THE CHICAGO ELECTRIC CLUB.

The banquet of the Chicago Electric Club, held at Kinsley's, Friday evening, June 27, was a decided and magnificent success notwithstanding the abnormally high temperature under which the city has been suffering for the past few days. The attendance was large among both the club members and their friends, and the fair sex, without whom an occasion of this kind would be but a tame and uninteresting event, were well represented. A magnificent repast was served in Kinsley's handsome banqueting hall and ballroom. The tables were beautifully and tastefully decorated with flowers, and the viands were enjoyed to the accompaniment of the delightful music of the harp and the tinkling strains of the mandolin, which was by no means the least attractive feature of the entertainment. After dinner the gentlemen retired for a short time to the club room, where two highly interesting papers were read, one by Prof. J. E. Siebel on "Thermo Chemistry in Relation to Electromotive Force," and the other by J. K. Pumpelly, on "The Storage Battery in Traction Work."

After this, dancing was the order of the evening, and a delightful entertainment appreciated by all was brought to a close about 1 P. M. The following prominent in Chicago and neighboring electrical circles were among those present:

Alexander Kempt and ladies; John Barton Payne; J. B. Carney and wife; J. K. Pumpelly; W. B. Pearson; Ernest Hœfer; W. A. Kreidler; A. C. Durborow, Jr.; J. W. Dickerson and Frank L. Perry; G. M. Smith; Geo. Buckley; Thos G. Grier; B. E. Sunny; Fred. DeLand; W. A. Hovey; R. E. Lee; H. A. Armstrong; Geo. Cutter, wife and lady; Chas. G. Armstrong; H. R. Hinson; Edwin R. Crolius; Gus A. Harter; Wm. H. Harding; C. M. Spaulding; Myron A. Knapp; W. J. Buckley and lady; F. E. Degenhardt and wife; Geo. C. Bailey; Chas. E. Gregory; D. B. Dean; W. S. Boyd; F. M. Ireland; S. J. Keese and wife of Los Angeles, Cal.; K. McLennan and wife; H. L. Reiwitch; A. Scheible; W. W. Nicholls and W. Forman Collins of and many others. Much praise is due the entertainment committee who so ably carried out all the arrangements and made the evening most agreeable and one to be remembered by all present.

LITERATURE.

Brown's Directory of American Gas Companies. Compiled by E. C. Brown. *Press of "Progressive Age."* New York, 1890. Price, $5.

THIS is one of the most useful and accurate publications of its class, and has now made its third annual appearance. It is something more than a mere directory list, there being given very full statistics in regard to each company. It appears that there are now 1,048 gas companies in America, or about 500 short of the number of electric light companies, and as 304 gas companies are doing an electrical business, the proportion in favor of electricity as an industry is, on this basis, fully two to one. Mr. Brown has included also the natural gas companies and a full list of the members of the American Gas Light Association, Ohio Gas Light Association, Western Gas Light Association, etc. There is also a very interesting little section giving explanations of the various "processes" mentioned in the work. Another section shows graphically the growth of water gas lighting, the total of plants being no fewer than 367. The work is prefaced by a large, clear map on which are the names of all the gas towns of the United States. The work is clearly typed, the information desired can be gathered at a glance, and the volume is rendered thoroughly substantial by being bound in cloth boards.

The Electric Railway of To-day. By H. B. Prindle, 55 pages. Illustrated. Boston, Mass: *E. B. Stillings & Co.* 1890. Paper, 50 cents; cloth, $1.

This is an excellent work, for which there should be a very general demand. Mr. Prindle gives not only a popular description of electric railroading, but enters into a clear and intelligible discussion of the technical points involved, and offers a number of shrewd suggestions as to the lines along which progress may be expected. The illustrations are excellent, many of them being very useful and interesting details of construction and operation. Any person can form an idea as to the methods adopted, even if he has never seen an electric road running; and we can readily imagine that to some railroad superintendents the diagrams would be very helpful. The book concludes with a list of electric roads building or operating May 1. We congratulate Mr. Prindle on his neat and timely little book. He should now repeat the experiment with the stationary motor.

REPORTS OF COMPANIES.

AMERICAN BELL TELEPHONE CO.

The American Bell telephone statement of instruments for the month to June 20, records a net increase of 1,414, or more than 50 per cent. of the increase for the half year, as see the following :—

Month June 20.	1890.	1889.	Increase.
Gross output	7,758	6,511	1,247
Returned	1,927	2,094	*169
Net output	5,831	4,417	1,414
Since Dec. 20.	1889-90.	1888-9.	
Gross output	33,577	30,216	3,361
Returned	12,104	11,281	823
Net output	21,473	18,935	2,538
Instruments in use June 20	466,334	430,476	35,858

*Decrease.

THE INTERNATIONAL OKONITE COMPANY (L'T'D.)

The announcement is made of the formation of the International Okonite Co., Limited, to handle the large business in Okonite wires and cables that has grown up under the spirited and enterprising management of the Okonite Company of this city, and to develop a similar business in England. The capital of the new company is represented by 17,000 preference shares of £10 each; 17,000 ordinary of £10 each, and 1,000 six per cent. debentures of £100, being a first charge on the whole undertaking. The preference shares are entitled to 8 per cent. preferential dividend, and to a bonus of 2 per cent. additional out of surplus profits every year after the ordinary shares receive 15 per cent. From the remaining profits the ordinary shares will then be entitled to a bonus of 5 per cent. It is stated that the net profits of the Okonite Company in 1887 were $37,601; in 1888, $51,207; in 1889, $115,802; and that in 1890 they bid fair to reach $200,000. The property acquired in England is that of Shaw & Connolly, the wire and cable manufacturers at Manchester, who will add the manufacture of Okonite specialties to their existing business.

It is stated that 5,500 preference and ordinary shares have been applied for by the directors, besides those applied for by their friends; and that 11,300 preference and ordinary shares will be allotted in part payment of the properties. The businesses are to be taken over as going concerns from January 1, 1890.

The negotiations have been carried through chiefly by Mr. F. Cazenove Jones, of the Okonite Co., and Mr. F. L. Rawson, of Woodhouse & Rawson United, Limited. The directors of the new company will be Lord Greville; Samuel Pope, Esq., Q. C.; Major Jones, R. A.; Sir Alex. Armstrong, K. C. B., F. R. S.; H. Dobree, Esq.; J. H. Cheever, Esq.; J. L. Martin, Esq.; H. Durant Cheever, Esq.; F. Cazenove Jones, Esq., and W. L. Candee, Esq.

The price to be paid by the company for the businesses to be acquired as going concerns (all debts being paid and received by the Okonite Company and Messrs. Shaw and Connolly up to 1st January, 1890), including the leases of the buildings, the plant and machinery, stock in trade, patents, licenses, trade marks, processes, contracts, and good-wills, has been fixed by the vendors, Woodhouse and Rawson United, Limited, who are the promoters, at the sum of $1,576,201, of which $549,650 is payable in Preference and Ordinary Shares and $161,505 in Debentures, and the balance in cash; the vendors pay all preliminary expenses up to the first allotment of shares. The present issue of capital after payment of the purchase money will leave over $533,500 for working capital.

Winslow, Lanier & Co. are the bankers to receive applications for shares and debentures in this country.

DIVIDENDS.

THE INTERNATIONAL BELL TELEPHONE CO. has declared a semi-annual dividend of 3 per cent., payable July 1.

THE CONSOLIDATED ELECTRIC LIGHT CO., of New York, has declared a quarterly dividend of 1¼ per cent., payable July 1.

STOCKS AND BONDS.

THE EDISON ELECTRIC ILLUMINATING CO, of this city, has made application for the listing of $2,000,000 first mortgage 5 per cent. convertible gold bonds.

THE CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY has filed notice of an increase of capital stock from $5,000,000 to $6,000,000. The stock is to be given to the holders of the $1,000,000 construction certificates, issued in the early part of the year for the extension of its cable to Valparaiso, Chili. The cable will be finished Jan. 1, 1891.

REJECTING THE NEW YORK LIGHTING BIDS.

All the bids made by the electric light companies for street lighting were rejected last week by the Gas Commission. The proposals put in last April showed that the companies, as though by arrangement, had united in asking about 25 per cent. more than last year's prices. The companies allege that the increase was necessary because of the rents of the subways and the removal of the overhead wires. The Gas Commission, however, decided that the bids were altogether too high, and if the contracts were granted the appropriation which was made on the basis of the old rates would be exceeded.

The commission ordered advertisements for new proposals and decided to go back to gas for street-lighting purposes if the bids are not low enough to bring the charges for electric lighting within the appropriation.

THE PLANT OF THE HALIFAX, N. S. ILLUMINATING AND MOTOR CO.

A very fine station has just been started at Halifax, N. S., by the Halifax Illuminating and Motor Co. The electric station is erected on Moren's Wharf, which is situate very centrally at the south-eastern portion of the city. This property was purchased by the company some time in the month of November, and consists of a lot with a frontage on Water street of about fifty feet and runs eastwardly to the harbor about 230 feet, where the width for about one hundred feet is over eighty-five feet. The water lot is 80 by 300 feet, and has upon it a new and capacious wharf, while the depth of water is ample for all kinds of shipping. The station is a substantial two-story brick building. The boiler room is about forty feet square and the engine and dynamo room is 40x50 feet. The boiler room is furnished with four tubular boilers six feet in diameter and 16 feet in length, made of half inch steel and so constructed as to stand a pressure of at least 120 pounds to the square inch. Each boiler connects from the top by an eight inch steam pipe with a twelve inch pipe running the whole length of the engine room, about three feet from the second floor. In the engine room nearly beneath this pipe are set four compound engines, one of the Armington & Sims type and three of the McIntosh & Seymour engines, for which John A. Grant & Co., of Boston, are the agents. These engines were all made to order and specially designed in all their running parts for the special work of this company. The dynamos belt direct from the fly wheels of the engine. The engines are all high speed and are run at the rate of about 260 revolutions to the minute. Their united capacity aggregated about 600 h. p.

The electrical plant consists of seven new arc dynamos, each of a capacity of fifty lights, of 2,000 of candle power, two incandescent alternating dynamos, of a united capacity of 3650 sixteen candle power lights. The switch board covers an area of about 30x12 feet, is made of black walnut and cherry and in its arrangement and construction was designed by the superintendent, R. A. Cogswell.

J. W. DeBlois is manager of the company; R. A. Cogswell, superintendent; and W. Wisdom, chief engineer.

LEGAL NOTES.

SWAYING WIRE—W. B. SHELDON vs. W. U. TELEGRAPH CO.

Judgment for $3,346.68 is affirmed in favor of Wilson B. Sheldon, who sued the Western Union Telegraph Company to recover for personal injuries received by running against a swaying wire extending from one of the company's poles in a highway in the town of Beekman, Dutchess County. The question involved was: Was it a careless and unwarranted use of the highway by the company, and this the Court of Appeals answers affirmatively.

TELEGRAPH PATENTS.—J. E. BLOOM vs. J. M. SEYMOUR AND F. J. PATTEN.

Col. John E. Bloom claims that James M. Seymour and Francis J. Patten are endeavoring to deprive him of his interest in certain patent-rights in connection with valuable multiplex telegraph inventions, and he has obtained from Judge O'Gorman of the Superior Court an order, with a temporary injunction, requiring them to show cause why they should not be restrained from parting with the patents pending his suit to establish his interest in the property. Patten was the inventor of the instruments, and, as claimed, he contracted with Bloom for the sale of them, and the contracts were duly recorded. Patten afterwards made a similar contract with Seymour. Col. Bloom in his suit demands $200,000 damages, but he alleges that both Patten and Seymour are unable to pay any judgment which may be obtained against them. The defendants, through Semple & Cahill, have demurred to the complaint. This demurrer has not yet been passed upon by the court. The system in question was fully illustrated and described in THE ELECTRICAL ENGINEER, of June 18.

TEARING AWAY RIVER CABLE—WESTERN UNION CO., vs. INMAN STEAMSHIP CO.

Judge Brown of the United States District Court in this city handed down on June 24 a decision in counter suits for libel brought by the Western Union Telegraph Company and the Inman Line Steamship Company, respectively, finding in favor of the steamship company and dismissing the libel brought by the Western Union. The litigation arose over the tearing away of twelve cables of the Western Union Company by the propeller blades of a steamer becoming entangled in them while attempting to swing out from a North River pier. The cables got so completely entangled in the blades that the vessel had to be placed on a dry dock for repairs. The steamship company's claim was for $2,000 damages, which is allowed. The amount claimed by the Western Union Company was $10,789, which was spent in repairing the broken cables, and $50,000 addition for damages sustained by the company's being deprived of the use of the injured cables during a period of sixteen days that it took to restore them to proper working order. The accident occurred on August 19, 1887.

In the suit brought by the Western Union Company, the claim was set up that it had the exclusive right to the use of the mud or silt for its cables, and that the propeller of the *City of Richmond* struck the cable while it lay embedded below the surface. Judge Brown, in his decision, says that such a right is not upheld under the language of the act of Congress relating to submerged telegraph cables. He points out that the act permits cables to "go under water, but not so as to obstruct navigation." Nothing in the act, he declares, gives any absolute right to lay cables in all cases on the very top even of solid bottom. Vessels docking near the point where the accident occurred have frequently to plough their way through navigable mud.

"There can be," he adds, "no practical difficulty in sinking cables so deeply as not to possibly interfere with the movements of vessels in any and all emergencies of navigation. The use by steamers in this harbor of the undefined margin of silt or mud between the solid bottom and clear water is necessary. Every inch that can be utilized is needed and should be scrupulously preserved for the uses of navigation against all unnecessary interference."

ELECTRICAL EXECUTION—KEMMLER vs. DURSTON.

The case of the people ex rel. Kemmler *vs.* Durston, warden of the Auburn State Prison, came up before the New York State Court of Appeals on June 23. W. Bourke Cockran argued for Kemmler on the sole question whether the Legislature had the power to legislate so as to take away any of the duties or powers of any sheriff of any county as it did in the present case and invest another officer, as in this case with that power. He claimed that the law was unconstitutional and void because it assumes to deprive the sheriff of Erie County of powers conferred on him by the Constitution. He submitted that the provision of the Constitution which guarantees to the electors of the various counties in the State the right to select sheriffs by popular suffrage, confers upon them the right to select an officer who shall forever execute the powers which were vested in the sheriff when the Constitution took effect, and that when such officer is shorn of any of his powers that provision is violated. Counsel argued that the act, so far as it attempts to give the custody of the relator to the warden being void, and the relator being detained by a person not having a shadow of authority, and being confined out of the county of his conviction and in an unauthorized building, it follows that he is illegally restrained and deprived of his liberty. Counsel asked that the Court should reverse the order of the General and Special Terms and make an order directing the warden to discharge the relator from custody.

Attorney-General Tabor began his argument by reviewing the course of the counsel for Kemmler in going through all the courts in the country in behalf of his clients when Chief-Justice Ruger cut him short by remarking that further argument was unnecessary, as the Court was ready to render a decision at once. The decision was in effect, that the Court believes that the Legislature had the power to make the law in question; and the decision of the lower court was affirmed.

INVENTORS' RECORD.

Patents issued June 24, 1890.

Alarms and Signals:—*Burglar-Alarm*, J. Winegarden, 430,979. *District Police and Fire Telegraph*, C. C. Drake, 430,992.

Conductors, Conduits and Insulators:—*Insulator*, W. H. Seamon, 430,696. *Composition of Matter*, F. N. Boxer, 430,766. *Insulating-Joint*, E. P. Gennert, 430,846.

Galvanic Batteries:—*Galvanic Battery*, J. H. Davis, 430,990.

Distribution:—*Regulation System for Electric Circuits*, C. O. Mailloux, 430,868.

Dynamos and Motors:—*Regulator for Dynamos*, W. H. Elkins, 430,634. *Dynamo or Magneto-Electric Machine*, T. A. Edison, 431,018.

Lamps and Appurtenances:—*Electric-Lamp Support*, James Chase, 430,622. *Incandescent-Lamp Hood*, J. Heath, 430,645. *Arc-Lamp*, J. J. Wood, 430,722. *Manufacture of Incandescent Lamps*, T. A. Edison, 430,932. *Filament for Incandescent Lamps*, T. A. Edison, 430,933. *Electric Lighting System*, T. A. Edison, 430,934.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in July, 1890.

Reported for THE ELECTRICAL ENGINEER, *by* F. B. Brock, *Patent Attorney, 639 F street, Washington, D. C.*

Recorder, F. S. Baldwin, 140,340, July 1, 1873. *Printing Telegraph*, T. A. Edison, 140,487, 140,488, 140,489, July 1, 1873. *Railway Signal*, F. L. Pope, 140,536. *Gas Lighting*, A. Potter, 140,591, July 8, 1873. *Connector*, S. D. Field, 140,618, July, 8, 1873. *Railway Signal*, H. W. Spang, 140,737, July 8, 1873; F. L. Pope, 140,790, July 15, 1873; D. Rousseau, 140,953, July 15, 1873. *Printing Telegraph*, G. M. Phelps, 141,076, July 22, 1873. *Recorder*, J. C. Hinchman, 141,352, July 29, 1873. *Railway Signal*, D. Rousseau, 141,387, July 29, 1873; H. W. Spang, 141,395, July 29, 1873.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

NEW FORT WAYNE PLANTS.

Mr. H. C. Adams, the agent of the Fort Wayne Electric Co., 115 Broadway, advises us that their Mr. C. S. Knight has just closed a contract with the United Gas Improvement Co., of Philadelphia, for 600 new Wood arc lights to be run in connection with their gas works at Kansas City, Mo.

The New York office has also closed a contract with the Raritan Electric Light and Power Co., Perth Amboy, N. J., for a 600 light Slattery alternating incandescent plant.

NEW WORK OF THE INTERIOR CONDUIT AND INSULATION CO.

The Interior Conduit and Insulation Co. are now making carload shipments daily, of tube, throughout the country. The new underground tube seems to have met with a great deal of satisfaction. The company have a contract for furnishing the underground conduits for St. Paul and Minneapolis, and they have also sold several thousand feet to the Pennsylvania Railroad Company for their underground work.

They have made quite a shipment to Japan, on orders received from there, and will probably make a shipment to Germany during the coming week. The company's new and commodious quarters now enable them to turn out tubes in large quantities, although they have not as yet succeeded in catching up with the orders, but it is probable that this will be done before the middle of the coming month, as their output has been increased tenfold.

The initial job of this company, the Shoreham Apartment House, Washington, D. C., owned by the Hon. L. P. Morton, has now been in operation about eight months and never has given any trouble since the plant was turned over to the purchaser. That it is an unqualified success is evidenced by the fact that Mr. Morton is now preparing to build an extension of the Shoreham House, and it is specified by the architects throughout the entire new building. As this company is not doing any construction work, the architects desire, as a special favor, that it shall be put in under their supervision.

THREE MORE WESTINGHOUSE PLANTS.

The Merchants Electric Light and Power Company, of Frankfort avenue, Philadelphia, Pa., is an organization which has recently been established there by prominent citizens of the "City of Brotherly Love." The company has given a contract to the Westinghouse Electric Company for one of its 750-light alternate current apparatus.

Not long ago the Westinghouse Electric Company installed its alternate current apparatus in Salt Lake City, Utah, and now the report has been made that another town in the Mormon State is about to establish an electric light plant within its precincts. A company has lately been organized in Ogden, Utah, and the Westinghouse Electric Company is going to install alternate current apparatus for a central station plant of 1500 incandescent and 80 arc lights.

The streets of Rockville, Ind., are shortly to be lighted by the Westinghouse alternate current arc light system. A plant of 50 lights has already been contracted for and the installation of the machinery is to be immediately begun.

AYRTON & PERRY INSTRUMENTS.

We learn from Queen & Co., of Philadelphia, that, in consequence of the great demand for Ayrton & Perry's magnifying spring ammeters and voltmeters, they have much increased their already large stock of these instruments and can fill orders for all the regular ranges without delay. The cardinal points in these instruments, are portability, freedom from magnets, (hence they are not affected by dynamos), and direct reading scales which are at the same time proportional throughout. That the Ayrton & Perry meters are appreciated is shown from the great demand for them during the last few years. They have been and are now used very extensively on electric railroads.

TROPICAL AMERICAN TELEPHONE COMPANY.

The Tropical American Telephone Company will close its books July 1 for the annual meeting July 8. The company reports its business increasing and its field broadening every month, and the management hopes to earn 10 per cent. on its business for the past year. It starts out with an order for 500 complete sets of instruments for one sub-company, an order of 100 sets for a second, and 300 sets for a third, beside a large order for Brazil. There has been acquired, to be turned over to the Tropical company July 1, control of the Williams annunciator drop, patented April 8, 1890, used in small exchange switchboards. This will enable the company to manufacture its own switchboards and levy a royalty on all drops of the above pattern used in the United States.

SUCCESSFUL TRIAL OF A STORAGE BATTERY CAR IN PROVIDENCE.

The United Electric Traction Company, of New York, have made a successful trial trip of their new car on the lines of the Providence street railway. The car is of the same pattern as those run for a while on Fourth avenue, New York, and is very comfortable. Power is applied by two Thomson-Houston motors, and the car floor is one step above the platform. There are two iron folding gates at each end of the car. The car is lighted by six 16 candle power incandescent lamps, and weighs seven tons with all its appurtenances. The motors are 10-horse power each, and are wound for 250 volts. Underneath the seats on each side of the car there are six trays of cells and nine cells in each tray, making 54 cells on each side and 108 in the car. By what is called the elevator system, the cells may all be removed from the car on the outside and another set be substituted in the space of one minute.

THE WIGHTMAN ELECTRIC MANUFACTURING CO.

This company, which has just been organized with headquarters at Scranton, Pa., proposes to manufacture specialties and to give special attention to all kinds of electric railway repair work, as well as electrical repairs in general. They have recently brought out an improvement in the method of winding motor armatures, particularly in the connections of the winding with the commutator, by which these are preserved intact, and the troubles heretofore encountered are entirely overcome. Mr. Merle J. Wightman, the well-known electrician, lately associated with Prof. Elihu Thomson, will be the electrician of the company, which is already busy on numerous orders. The officers of the company are: President, Lathrop R. Bacon; vice-president, Merle J. Wightman; secretary and treasurer, Horace E. Hand; and general manager, Herman Bergholtz.

THE RAE-PUMPELLY STORAGE CAR.

The new storage battery car built by the Detroit Electrical Works, Detroit, Mich., made a trial trip last week from the foot of Woodward avenue to the Mack road and Gratiot avenue and return for the benefit of the city railroad officials. The car climbed the steep grade from the river to Jefferson avenue without any trouble and made the entire distance at a much higher rate of speed while running than an ordinary horse car. This was accomplished by running until the car in front was reached, and then stopping until the car behind caught up. The car started on a grade of 7½ per cent., and ran around a switch and short curve. Notwithstanding these were severe tests, they were accomplished with ease, much to the surprise of the railroad men, some 30 in number on board. Amongst the street car men present were President George Hendrie, Treasurer Strathearn Hendrie, Secretary Cameron Currie and Superintendent Hugh O'Brien. Others on the car were Hugh McMillan, Frank E. Snow, Frank B. Rae, the inventor of the motor, and Mrs. Rae, Eugene T. Hill, General Manager of the Pumpelly Storage Battery Company, of Chicago, and S. M. Heavenworth, all of whom expressed themselves as greatly pleased with the trip. The storage batteries employed are those manufactured by the Pumpelley Storage Battery Company, of Chicago, and invented by Mr. J. K. Pumpelly, who has proved in this experiment the success which he has already looked for in this line, that is, a storage cell that will stand any rate of discharge without the plates buckling or being injured, and one that will stand the rough usage entailed by car service while capable of being charged rapidly with a very large current, a very important point in railroad traction work.

Perhaps the most practical trip made with the car was on Sunday, June 15th, when one of the motor cars of the overhead system was put aside and the storage car was placed on the track to do its work on the regular trips. The German picnic of that day crowded all the cars, and for all this the storage car made a trip of 52 miles with one charge of battery, carrying very heavy loads. There was no trouble in handling the car, and as far as the public were concerned it appeared no different from the regular overhead cars. In several of the experiments a speed of 16 miles per hour was reached, and 12 miles was a fair average, although, of course, such high speed was not permitted in regular traffic. Mr. Rae has certainly succeeded in making the single motor, adapted according to his own plans for traction work with storage batteries, a great success. In fact, it is stated, the car shows a better average of work for the weight carried in batteries than shown in any of the recent data given by Mr. Anthony Reckenzaun of European storage car fame. The car has been shipped to Middlesborough, Ky., where it will go into regular daily operation, having been ordered by the street railway company there.

Mr. J. H. Mason, of Mason battery fame, has been doing a rushing business for some time past, and during the last month or two there has been an enormous demand for the battery for light motor work. Several hundred fan motors, mostly of the Perret type have been put in all over the country to run fans or sewing machines. His employees, as a relief from their heavy work, have organized a Fourth of July excursion to West Point.

THOMSON-HOUSTON STATIONARY MOTORS.

The Thomson-Houston Electric Company have just issued a very neat and handy little pamphlet on electric power. It gives a variety of details as to the work done by their motors, and contains a number of interesting illustrations. The motors built are all of the upright, single magnet type. They are ordinarily shunt wound, and are built for constant potential circuits of 110, 220 and 500 volts.

In the tables below are given some figures on the weight, space occupied, etc., of the motors from one to seventy-five horse-power.

TABLE I.

Class.	H. P.	Pulley.		Width of Belt in inches.	Belt speed in feet per minute.	Approximate speed of Armature.
		Diam. in inches.	Face in inches.			
2	1	4	1½	1	2410	2300
3	1½	4	2	1½	2300	2200
6	3	5	3	2½	2620	2000
10	5	6	4	3	2830	1800
15	7½	8	5	4	3350	1600
20	10	8	6	5	3350	1600
30	15	10	7	6	3670	1400
40	20	13½	9	8	4600	1300
50	25	14	9	8	4400	1200
70	35	14½	10	9	4410	1170
90	45	15½	11	10	4570	1125
120	60	17	12	11	4540	1020
150	75	19	13	12	4180	900

TABLE II.

Class.	Weight in pounds.	Floor space of motor in inches.	Floor space (including sliding base) in inches.	Outside Dimensions (including sliding base) in inches.		
				Length.	Width.	Height.
2	145	16½×10½	23½×16½	19	23½	17⅞
3	300	20⅝×13½	28½×21⅝	24	28½	$24\frac{3}{16}$
6	480	25 ×16⅝	24½×25	29½	24½	$25\frac{5}{16}$
10	700	26 ×18½	30 ×26⅞	31½	30	$28\frac{7}{16}$
15	1080	31⅝×21½	33½×31⅝	37½	33½	$31\frac{9}{16}$
20	1364	34½×23⅞	37 ×35	40	37	32⅞
30	1950	37 ×27⅞	40½×37½	44	40½	36½
40	3160	47½×30½	50⅝×49⅝	58	49⅝	41½
50	—	— —	52½×62	62⅝	62	43
70	*5100	55½×36½	57½×66½	$67\frac{5}{16}$	66½	46
90	6350	63½×39½	65½×75½	76½	75½	50½
120	7050	66½×40½	69½×78½	81½	78½	54½
150	10000	73½×46½	76½×88	89⅝	88	63½

NOTE.—The motors of the higher classes, from Class 40 inclusive, are furnished with cast-iron sliding bases.

* Approximate.

ELECTRICIANS AT ASHEVILLE, N. C.

Asheville, N. C., is rapidly becoming the centre of a number of electrical enterprises, and as the key to a fine mountain region is attracting a great many electrical men, who hunt and shoot and fish. A corporation called the Western North Carolina Mining Co. has just been formed by several well known electrical engineers and has acquired a magnificent hunting territory on the Hogback Mountain. It is rich not only in game but in minerals of all kinds. Club headquarters have already been built on the property, and a large party have just been enjoying themselves there, among the number being Messrs. W. D. McQuesten, W. J. Jenks, L. Stieringer, S. E. Barton, E. F. Davis. The vice-president of the company is S. B. Eaton, and R. N. Dyer is one of the trustees. It is believed that the property will in time develop into one of great value; and in the meantime it is an ideal pleasure ground for sportsmen.

EUREKA TEMPERED COPPER FOR COMMUTATOR SECTIONS.

The Eureka Tempered Copper Co., of North East, Pa., have received the following excellent testimonial from the Card Electric Motor & Dynamo Co., H. H. Walter, general manager, of Cincinnati:—"In answer to your inquiry of the 21st, will say we are very much pleased with the tempered copper we have bought from you for our commutator sections. The sections have all been true to size and as far as we can learn are out-wearing anything we have before been able to get. Though the cost is considerably higher than the ordinary copper, we have about decided to use the Eureka Tempered Copper on all the dynamos and motors of our manufacture."

THE WALKER ELECTRIC CO.

This company is now busy filling a number of orders for the Walker meter which was described in THE ELECTRICAL ENGINEER of April 9. The latest design embodies a number of improvements which still further simplify the apparatus and make its readings accurate to the last degree. Thus a recent test made showed that the indications of the recording meter corresponded exactly to the records kept by an attendant who watched and recorded the indications of an ammeter in circuit. As the meter also indicates a drop in the voltage of the circuit, it forms not only a valuable check to the consumer but a guide likewise to the lighting company as to irregularity of the service, which can then be remedied. As announced in our advertising columns the company is now fully equipped to take orders for this meter.

THE STANDARD ELECTRIC SUPPLY CO.

The Standard Electric Supply Company has been organized under the laws of the State of Massachusetts, with a capital of $10,000. The officers of the company will be Mr. Wm. P. Fairbanks, president; Mr. W. C. Woodward, treasurer; and Mr. G. D. Haynes, clerk. The company have taken handsome offices and salesrooms on the first floor of the New England building, 180 Summer street, Boston, and have a floor space of over 5,000 square feet. They will carry a full line of all electric light and railway supplies, and will have a number of specialties which will be published later.

WATERPROOF AND INSULATING PAPERS.

The Standard Paint Company, of 59 Maiden Lane, New York, announce two new grades of building paper. One whose trade mark is the "Universal" is prepared with their P. & B. compound, is thoroughly water proof, acid, alkali and gas proof in all respects. The other new brand is called the "Giant" building paper. This paper is completely saturated with water proof, acid and alkali proof and insulating material, and the work is so thoroughly done that the paper can be cut in any way and torn into bits and no particle of it will absorb moisture. Every fibre is thoroughly impregnated. The paper is said to be more water proof than leather.

AN ELECTRICAL BLOCK SIGNAL.

An audible electric signal for railroads was tested last week at the One Hundred and Thirty-third street station of the Suburban Railroad. The power of the apparatus is furnished by an electric battery, which operates a relay in the railroad station. From this relay wires run to the railroad tracks, the joints of which are insulated with leatheroid. When one train is on a block of track protected by the contrivance and another enters, the engineer of the latter will be warned by the falling into sight of a flat iron disc painted a bright red and the simultaneous ringing of a gong. Both are parts of the signal box, which is arranged within the locomotive cab. They are operated by an electric current which is formed at the track joint along a wire, one end of which is attached to the body of the locomotive and the other to the front truck of the first car. The circuit is made as the locomotive wheels touch one rail at a magnetized point and the car wheels another. The invention is designed to be of special use in snow storms, fogs, and cases of color blindness. Twenty signals will be placed on the Suburban road.

THE "NICKEL-IN-THE-SLOT" PHONOGRAPH.

A nickel-in-the-slot phonograph is the latest novelty in the line of machines that are calculated to give some return for the moderate sum invested. There is only one of these machines at present in the city, says the *New York Times*, but a number of them will be placed shortly in the popular hotel lobbies, bar-rooms, etc., as well as in the railway waiting-rooms.

The working of this new machine is exceedingly simple, and the work done by the reproducing instrument is really wonderful, the sounds being so clear and distinct that it is only necessary to close the eyes to make one imagine himself in the actual presence of the musician. When the nickel is dropped in it releases a catch that holds a rod, the end of which is in plain view at the right of the upper portion of the case which carries the machine. By pressing this handle in as far as it will go the phonograph cylinder is set in motion, and then if the ear-pieces are placed in the ears the music is plainly heard.

The length of time the sounds are continued is regulated by an attachment that requires setting, and which is not automatic until set, when it is sure, however, to stop the music at the exact time required. When the nickel does its work it drops into a little receiver in plain view behind a glass, where it remains until the next nickel is dropped in, when it is pushed down to the safe, which stands in the middle compartment of the case. In this compartment will also be kept a number of spare cylinders, so that a constant change can be made in the tunes played whenever the proprietors of the instrument wish to do so. In the lower compartment is kept the battery which works the phonograph.

The appearance of the case, which stands about four feet high, is very neat, and would attract but little attention were it not for the glass top, through which the little machine and the nickel-worked attachment are plainly visible. On top of the case the words "automatic phonograph" explain what it is.

PERRET ELECTRIC MOTORS AND DYNAMOS.

The Elektron Manufacturing Co., 79–81 Washington street, Brooklyn, have just issued a very handy vest pocket brochure entitled: "Information about small electric motors and batteries." The subject of small power is taken up and discussed for the benefit of the uninitiated public, in a very clear, simple and forcible manner, and the various points about primary and storage batteries are all admirably explained. Various illustrations are shown of the Perret small motor attached to sewing machines, fans, &c. With this goes a fly sheet price list for motors, batteries, fans, guards, &c.

The company have also published a large sheet of testimonials not only as to their motors but as to their slow speed dynamos for lighting. Of one of the motors, a printing house in Philadelphia say: "We don't know how we could get along without it, and it could not be purchased from us for three times the amount we paid for it, provided we could not get another."

A NEW THOMSON-HOUSTON FACTORY FOR MINING WORK.

The Thomson-Houston Co. has secured the estate of John Welch, Berkeley street, Lynn, for which negotiations have been for a long time pending. By this purchase they will be able to run the spur track from the Saugus branch of the Boston & Maine R. R. as originally laid out to the shipping department in factory H, and thence to the new factory C extension, and the testing house now in process of erection on Federal street. A section some 20 feet long only remains to be built to connect factory H with the railroad.

The latest factory to be built has been named "Factory J." It stands on Centre street, and will be used for the manufacture of electric coal cutting machinery.

NEW ENGLAND TRADE NOTES.

MR. EDWIN R. WEEKS, and wife, of Kansas City, have been welcome visitors to the Hub, during the past week, and have been cordially received by their numerous friends in this part of the country.

MR. S. S. SIAS, treasurer of the Boston Electric Light Co., and wife, celebrated the 25th anniversary of their marriage Saturday evening, at their residence on Agassiz street, North Cambridge. The house was brilliantly decorated and illuminated, and a number of guests were present from Boston, Somerville, Brookline and Cambridge. The couple were recipients of many elegant gifts, among them an elaborate cathedral chime clock from the directors of the Boston Electric Light Co.

THE ELECTRIC GAS LIGHTING COMPANY are never behind hand, and their enterprising general manager is constantly on the outlook for good things, and no one knows better than he how to push them. The latest circular, got up in Col. Burnham's usual tasteful style, is one calling attention to the Gethins improved gravity battery, specially adapted to closed-circuit work. This battery only requires to be brought prominently before consumers to be used exclusively, as its good qualities will recommend it wherever used.

FRANK RIDLON & COMPANY, who seem to enjoy a monopoly in New England, of the second-hand electrical business, have been quite busy this month in furnishing second-hand motors and dynamos to all parts of the country. Mr. Ridlon has the happy faculty of not only finding out where second-hand electrical apparatus is wanted but, what is just as important, where it can be had. He reports the following sales:—one 25 light Ball arc plant; one 200 light "W. E.' Weston incandescent plant; one 30 light Brush arc plant; two Robinson Foster motors; one 2 h. p. Cleveland motor; six 7½ h. p. railway motors; three ⅛ h. p. Perret motors, and one Crocker-Wheeler motor. Mr. Ridlon has pleasant offices in the Estes Press building.

THE EASTERN ELECTRIC CABLE COMPANY, of Boston, are just completing additions to their factory which will give them facilities for 50 per cent. more machinery to turn out their famed Clark wire. Their sales this year have been enormous, and they are at present doing a business of over 70 per cent. more than for the corresponding period last year, having for the past few months kept two complete gangs of men at work, one in the night and one in the day time. Their "Hub" line wire, recently introduced has met with much success, and they are recently in receipt of a most flattering testimonial from the Buffalo Association of Fire Underwriters, who tested the wire for 93 days most thoroughly. The wire was immersed in salt water for 75 days, then it was allowed to dry for 28 days, immersed in salt water again for 24 hours, and tested with 1,500 volts with a delicate galvanometer and no deflection observed. No better guarantee of its thorough waterproofness could be given.

THE EVANS FRICTION CONE COMPANY, of Boston, are rapidly becoming recognized as furnishing a reliable system of frictional driving between engines and dynamos, and recently have been quite busy with all classes of work. By the use of their system, dynamos can either be driven direct from the engine or from countershafting when a large engine is used. They have recently been giving attention to equipping ship plants, as their system is specially adapted when only a limited space is available. On the S. S. "Portland," of the Portland Steam Packet Company, which is equipped with 400 lamps, they have installed their system on two "E. I." Thomson-Houston dynamos driven from the one fly-wheel of an Armington & Sims engine. The plant is situated on the keelson of the boat and occupies a total space of 7½ feet by 10 feet. The "H. M. Whitney," of the Metropolitan Steamship Company, which is equipped with a 200 light Thomson-Houston plant, with Armington & Sims engine, is also fitted with their friction system of driving, and the plant occupies a space of 4½ feet by 6½ feet. Messrs. Charles L Seabury & Company, yacht builders, of New York, are installing a Loomis plant to furnish one search light and 90 incandescent lights in one of their new yachts, to be driven by an upright engine, and the Evans system will be used. We have yet to learn of any failure in any of their installations, and the Evans system of driving bids fair to become very popular as it becomes more widely known.

WESTERN TRADE NOTES.

MR. "NED" FOX, the representative of the Phœnix Glass Company, is in town at the Tremont House. He intends remaining in the city for a couple of weeks. The Phœnix Company have recently produced some very fine novelties in their line.

THE PUMPELLY STORAGE BATTERY CO., 129 La Salle street, are showing some very handy surgical batteries, 2 cells in one case, for cautery purposes, weighing complete about 12½ lbs. and having a capacity of 25 ampere hours. These cells are readily and conveniently charged by a battery of 5 bluestone or other primary cells.

SHAY, STEPHENS & COMPANY will shortly remove from their present quarters at 154 Van Buren street, to new and larger premises on the West Side. This will enable them to carry a full line of samples, insulators, battery jars, electric light globes and all the various other specialties relating to their business. The company are replete with orders and are doing a very large and growing trade.

W. P. ADAMS & COMPANY have sold 3 compound non-condensing engines, aggregating 600 horse-power, for the new Edison South Side Central Station plant. This makes an aggregate of 1000 horse-power in all sold to this company in three weeks. During a month and a half's business this firm has sold engines to the extent of 2600 horse-power, thereby beating previous records. Mr. J. E. Wilson, the junior member of the firm, is still on the jump and, not even altogether satisfied with the present amount of business, is still looking and hustling for more.

MR. C. H. CONE, 108 Adams street, the well-known agent of the Findlay Glass and Carbon Co., of Findlay, O., has taken hold along with his other specialties of the Baxter motor, and will be the general Western agent for these machines, which are in operation everywhere and spoken of very highly by those who have used them. Both from Mr. Cone's great ability in this line and the excellence of the machine, a large business will be done; and the Baxter Electric Motor Co. could not have placed the task of pushing their motors in this section in better hands. Amongst numerous recent sales of batteries Mr. Cone reports the following: 1000 cells to the McIntosh Battery Co., Chicago, for medical work; 1200 cells to D. Fitzpatrick, Chicago; 500 cells to Miles & Hale, St. Paul; 500 cells to Novelty Electric Supply Co., Cincinnati, O.

THE WESTERN POWER CONSTRUCTION COMPANY have now got settled in their magnificent new offices in the Rookery Building, 144 Adams street The offices are furnished in a handsome and sumptuous manner, and, being located on the ground-floor, are very handy and accessible. This large corporation is the outcome of the well-known firm of W. P. Adams & Co., who, finding that their business was to be so abnormally great in handling the McIntosh and Seymour engines, have succeeded in interesting some prominent Chicago capitalists in an enterprise that bids well for success. They have, therefore, formed the above-named organization with a capital stock of half a million dollars, all of which has been already subscribed for. They have secured the agency for the famous McIntosh and Seymour engines from the Allegheny Mountains to the Pacific Coast, and as outlined in their prospectus, they are now prepared to make propositions for the complete erection of steam power plants in this territory, and where necessary, will also erect the building. Mr. Waldo P. Adams is the genial and experienced general manager of the new company and Mr. James E. Wilson, formerly representing the interests of J. A. Grant & Co. in the west will take a prominent position. They have also secured the services of Mr. Charles S. Colson, who has had an extended experience in steam engineering. They will be pleased to receive a call from their numerous friends.

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.

GEO. M. PHELPS, President. F. R. COLVIN, Treas. and Business Manager

Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. X. NEW YORK, JULY 9, 1890. No. 114

What is there so real, what is there so enduring, what is there so useful, as a new idea so stated that it can be employed and lead to a useful practical result?—J. J. Storrow.

DEPTFORD.

FOR nearly two years the electrical profession has been kept in great uncertainty by conflicting rumors regarding the state of affairs connected with the big Ferranti station at Deptford near London. At one time the public was informed that the great 10,000 volt alternating machines had proved defective, and again, that the conductors laid had succumbed to the strain, so that, in consequence, current had to be transmitted at a reduced potential. These statements, going out unqualified, naturally had a tendency to cause the Deptford enterprise to be looked upon in the nature of a failure so far as the original plans of the designer were concerned. But when Mr. Ferranti announced his intention of building and operating machines and circuits at 10,000 volts, it is safe to say that he had maturely considered the undertaking; and the courage and enthusiasm which have thus far accompanied his work may possibly be traced to the touch of Yankee blood in his veins. Whatever may be the opinion as to the advisability of operating machines of the capacity employed by Mr. Ferranti, we think it is now conceded that there is no obstacle to their successful operation, the earlier defects being mostly due to imperfect construction which has since been remedied. But the nature of the circuit to carry 10,000 volts pressure involves considerations of perhaps a higher order even than those involved in the construction of the dynamo. In the latter we may reduce the potential at two contiguous points as much as we desire by increasing the number of coils and hence decreasing the difference of potential between them. Not so, however, with the conductors of the exterior circuit, which are subjected to the maximum strain at every point in their course. Those who are familiar with the difficulties of confining currents of but a few thousand volts to their proper channel will realize that the work undertaken by Mr. Ferranti was none of the easiest and that he deserves all the encouragement which can be accorded to a pioneer, for such he certainly is. The exact condition of affairs existing to-day at Deptford is well set forth on another page and is, we think, sufficient evidence that complete success will ultimately be attained. It will be observed that even now current is being transmitted at a pressure of between 5,000 and 6,000 volts over a temporary cable, and the results already obtained with the new type of Ferranti cable are of the most encouraging character. Our readers will no doubt be interested in the constructive details of the new leads, which exhibit, to the full, Mr. Ferranti's ingenuity. Every electrical engineer who has had the good fortune to inspect the works at Deptford, will admit that Mr. Ferranti has struck out on a new path with a confidence and ability that should carry him on to success.

AFTER OPERATING, WHAT?

THE New York *Sun* published recently an interesting article with the above caption, in which the assertion was made that one-third of the operators in the country are continually preparing themselves for other professions, while the other two-thirds are continually thinking about it. Coming to particulars, it says that of the 100 men working on the regular night force in the Western Union main office at 195 Broadway, 36 of them are either studying or working at something else in the day time, as follows:—Doctors, 8; lawyers, 6; ministers, 3; brokers, 3; actors, 2; theatrical managers, 2; real estate dealers, 2; inventors, 2; book agents, 1; manufacturers, 1; civil engineers, 1; authors, 1; commercial business, 1; electrical supply agents, 1; composer of music, 1. It is probably the fact that the telegraphic business soon loses its glamor for ambitious young men, and that thereafter they turn their thoughts to other fields, where promotion and riches are likely to be enjoyed sooner. But it is a little bit striking that the above classification of emigrants from telegraphy does not include a single student of electrical engineering. In the old days, it was from the telegraphic ranks that the best recruits for telephony and electric lighting were drawn; and it would seem only natural that more of the men seeking to cut loose and better their fortunes should perfect the electrical training they have already received. But it is not so. On the contrary, a large number of the new men coming into the profession either hail from the technical schools and universities, or are attracted from non-electrical fields, in which, as the result of special bent or taste, they have secured some kind of expert practical knowledge for themselves. A great many telegraphers become connected with electrical enterprises, but that is not exactly the same thing as becoming skilled electrical engineers, able to handle not only circuits, but knotty formulæ and modern steam plants, and all with equal ease.

THE GROWTH OF THE ALTERNATING SYSTEM.

It was practically not until the spring of 1887 that the alternating current incandescent lighting system came into commercial operation in this country. At the February meeting of the National Electric Light Association in Philadelphia it was described and discussed as a thing quite rare and novel and of dubious value. Looking over the list of central stations on their alternating system just issued by the Westinghouse Electric Company, we find a detail of no fewer than 301 central stations, of a total generating capacity of 554,350 lamps of 16 c. p. or 886,960 lamps of 10 c. p. This is an enormous growth, and, of course, does not by any means represent all the alternating plants in the country. But even if it stood by itself, this list would be evidence of amazing development and would show beyond cavil that the alternating system had found a vast territory awaiting occupancy by it, and had already made a respectable start in filling that territory up. On a basis of about $30 per 16 c. p. light, this growth represents the handsome investment of not far short of $17,000,000 in these 301 central stations, for lamps, wiring, dynamos and steam or water plant.

Electric Lighting in the South.

In a comment last week upon *Brown's Gas Directory*, we noted that the electric lighting companies were in the proportion of nearly two to one, to the gas companies. It would appear that in the New South the ratio in favor of electricity is much greater. For example, during the first six months of 1886, 1887, 1888, 1889, and 1890, the number of new electric light companies in that section was 17, 33, 80, 134, and 127; as compared with new gas companies, 15, 24, 18, 12, 16. In other words, the figures are 391 to 85, or a proportion of over 4 to 1 in favor of electricity. The explanation of much of this is that there has been a considerable upbuilding of new cities and towns in the South, and that, naturally, the electric light has been preferred. The same explanation applies to electric railroads, the preference being given to electricity in the large majority of new roads.

Ohm's Law.

The science of electricity, like most of the sciences, is based upon but few fundamental laws, and among these Ohm's is unquestionably the most important. Indeed it may be said that the majority of the others are more or less directly derived from it, forming corollaries applicable in many ways. A clear understanding of this law, therefore, such as can best be obtained by actual demonstration, is highly desirable to implant in the minds of students; and the simple method described by Prof. Mayer, on another page, will be appreciated by all lovers of experimental science. The account of the history of Ohm's law evinces the remarkable penetrative powers of Ohm and the clearness of his reasoning.

The Edison Underground System.

The "solid" underground systems that have been put in up to date have, so far as we are aware, been discarded and abandoned, with one exception, which stands in striking contrast as a brilliant success. That exception is Mr. Edison's tube system, of which we were enabled to give a very complete and interesting description, with many illustrations, in our last issue. No authoritative data has been available since the Franklin Institute reports of 1881–5, and while the system remains the same in essentials, it has naturally undergone various modifications and perfections of detail in the five years that have elapsed since then. Unless the behavior of the New York subways improves soon, there will be a choice only between some such system as this and the large open tunnel; although some of the leading subway experts say we would be in as much danger from gas explosions even with the tunnels as we now are with the "ducts." It may be noted, in passing, that the recent pamphlet issued by the United Edison Manufacturing Company contains a number of interesting testimonials as to work done with the Edison system at the other extreme—using overhead bare copper conductors.

Watering a Station Under Difficulties.

One of the features of interest and importance in the newer stations is the provision for water supply. Of course where the station is planted on the river bank, the superintendent is exempt from any thrill attendant upon a little "tank drama" of his own; but we have known of instances where the worry of maintaining water supply was enough to turn a man's hair gray in a night. One friend of ours had the blissful experience, when the city water works went wrong, of keeping up his water supply for several weeks by means of oil tanks which the railroad brought in daily from a distance. His fear lest those tanks should get side tracked, and his delight when the precious supply ran in safely on time can be readily imagined. By all means let stations provide against shortness of water.

Mr. J. P. Barrett and The World's Fair.

We print elsewhere in this issue a copy of the petition asking for the appointment of Mr. J. P. Barrett, the electrician of the city of Chicago, as director of the electrical department of the World's Columbian Exposition. This petition is most influentially signed, and, as will be seen, carries with it the approval of all the leading men and houses in Chicago. While the matter is not one that concerns Chicago alone, it is evidently one in which that city has a deep interest, warranting a step of this kind; and we believe that the nomination will meet with general acceptance. Mr. Barrett is a public official, without commercial alliances, and should, from his long, practical experience, prove himself to be just the man for the post. We hope the appointment will be made.

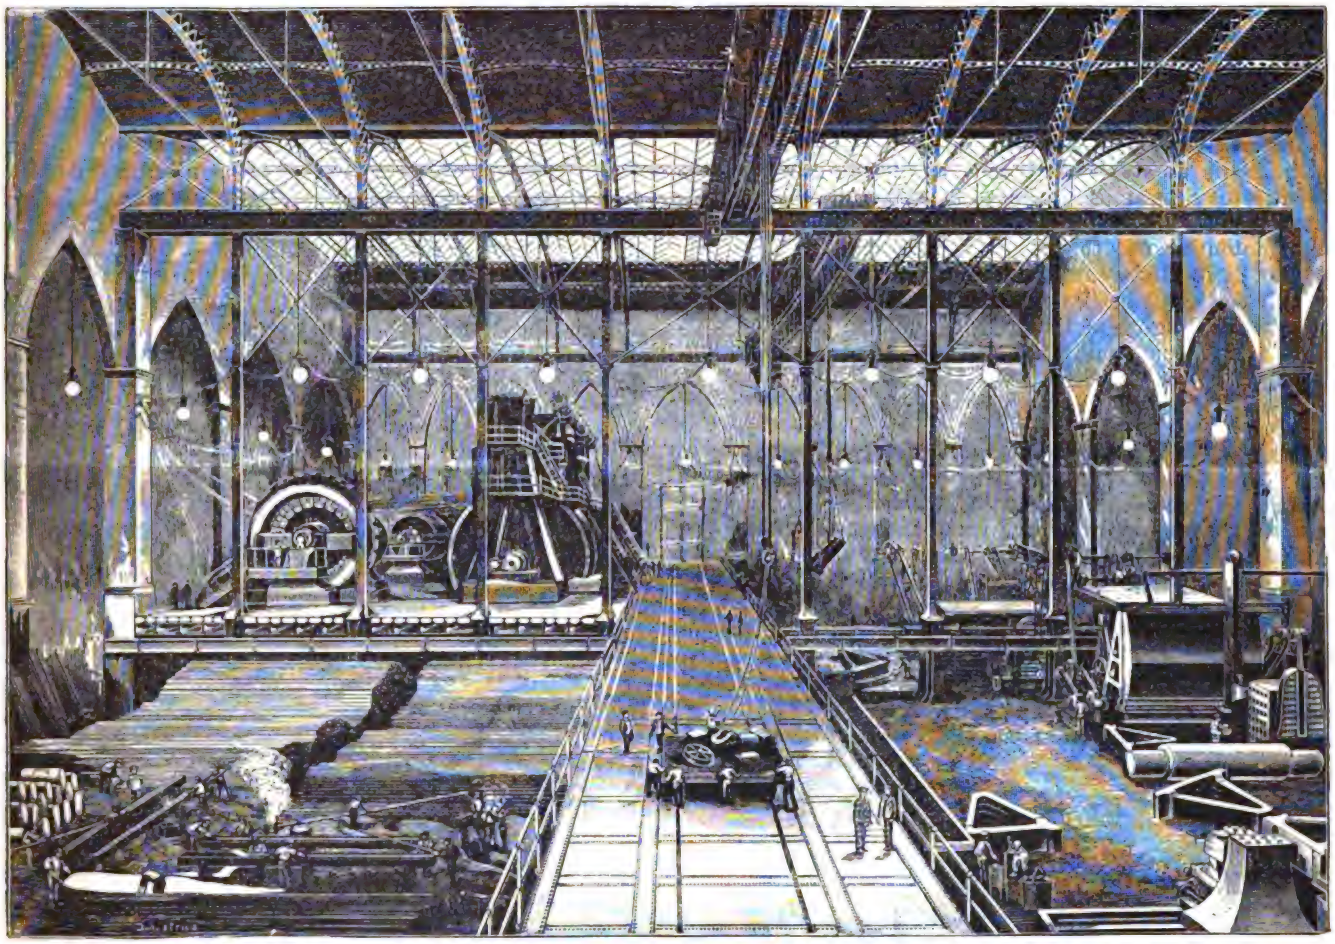
English Telegraphers.

Many of our American telegraphers are apt to imagine that a Government control of the telegraphs would bring them relief from all the unfavorable conditions under which they now labor. The state of affairs in England shows this idea to be unfounded. In fact, the telegraphers there are in a chronic condition of discontent, and just at the present time their feelings are so wrought up that they seem likely to go on strike again. It is even rumored that the authorities may send to America for men. Possibly there may be a few who would go, but if they did, it is hardly likely they would find America a pleasant country to live in on coming back.

THE DEPTFORD FERRANTI STATION.[1]

The Deptford station is, as is well known, anything but completed, as far as erection of the plant goes, but in one sense it may be said to have been complete before it was begun, because every detail was planned out with the greatest care and forethought before the actual work was commenced, and a description of this station now will probably give a fairly exact idea of what the finished station will be like, and will be more interesting to our readers, as the Deptford scheme is exciting so much attention at present.

The visitor on entering the building, which is illustrated in the accompanying engraving, is struck with its enormous size. At first one is lost in admiration of the pluck and enterprise shown in setting up business on such a scale, but the feeling is soon qualified by an uneasiness as to whether the pecuniary risk is not unnecessarily great in proportion.



INTERIOR OF THE DEPTFORD, ENGLAND, FERRANTI STATION.

The present position of the corporation as regards mains is this:—They have made and put down a mile or so of their own mains, but they are not in use. They have, therefore, to depend on the Fowler-Waring concentric mains. These mains are too small, and with the load now in use the loss over them amounts to over 1,200 volts. The outer conductor is only lightly insulated, and would not stand this, and the leakage all along the line from it to earth has given considerable trouble to the telephone companies. The corporation has therefore been obliged to use only the inner conductors of the cables, leaving the outer conductors idle. The action on the telephones due to the use of separate cables is avoided by crossing the leads frequently.

One engine and dynamo is now taking the Grosvenor Gallery work, and another engine and dynamo are ready for work. The cables now in use are Siemens' concentric for distributing mains at 2,400 volts, and Fowler-Waring for temporary trunk mains. The Ferranti concentric mains are being made, and about a mile has been put down, but they are not in general use yet. They have been officially and otherwise tested; by cutting through the outer insulation with a pick-axe until the outer conducting tube is exposed, it may be safely grasped in the hand, as might be expected. The joints are long cones, so that any leakage would have to pass along a considerable distance to get to the other conductor. No doubt the ozokerite will readily unite perfectly. In fact, ozokerite has, we believe, properties analogous to pure rubber, in the facility with which it will unite under pressure. A little warmth would certainly unite it. In this point vulcanized rubber is inferior. It will never repair a leak in its substance, whereas pure rubber, and probably ozokerite, will.

It has been said over and over again that the Deptford scheme is a wild experiment, and is more or less certain to end in a dismal failure which will do incalculable harm to the industry generally. The first novelty is transmitting electrical energy at 10,000 volts. This is simply a question of insulation, but that is no small matter. The whole question of insulation for very high electromotive forces is very obscure. It would seem quite likely that it is not a question of the maximum difference of potential between the two leads—in this case two concentric tubes—but of the rate of fall of potential; that is to say, the difference of potential between the faces of each little element of insulation. For instance, we can easily imagine that india-rubber will stand a stress of say 1,000 volts per millimetre, so that a large sheet one centimetre thick would stand 10,000 volts. In this case all the portions of the rubber have to stand equal stresses. But if the rubber is

1. *Industries.*

wrapped round a cylindrical conductor, the inner layers will be subjected to a greater stress than the outer; and if the stress is near the maximum, thickening the coat of insulation can do little good. The rate of fall of potential depends on the diameter of the cylinder, so that the larger the conductor, the easier it is to insulate it so as not to break down. On the other hand, the larger the conductor the lower the insulation resistance measured in megohm miles, so that we have the paradox that a small conductor which shows a high insulation resistance may be more likely to break down than a large one with a comparatively low insulation resistance taken in megohm miles.

Then, again, there is the question of insulation conductivity; it may, or may not, follow that a material which conducts slightly, is liable to break down. It is most probable that a dielectric breaks down suddenly, and that a microscopic conduction has nothing to do with this. If that is the case, insulation resistance measurements give no indication as to safety against breakdowns, except in so far as they localize an incipient fault.

Returning to the Deptford trunk mains, there seems to be no reason why 10,000 volts is not practicable, especially with a conductor an inch in diameter; but great difficulty may be expected in the joints, even when coned, and especially if expansion and contraction have any chance of working the joints. We would again suggest that the difficulty may, perhaps, not be in making the joint to give a high insulation resistance, but in arranging it so that the fall of potential over the insulation is always gradual. The problem is, in fact, analogous to designing a static electric machine so that it has no corners to form discharge points. Ozokerite is tougher and more elastic than paraffine wax, and does not seem to develop minute cracks on solidifying.

THE FERRANTI MAINS.[1]

AMONG electrical engineering enterprises at the period of early development of the industry in England, the large central high-tension system at Deptford will remain noticeable, not only on account of the largeness of its conception, but also on account of the remarkable difference of opinion and statements of fact which have arisen about it.

We must first of all remind our readers that the scheme at Deptford comprises two engines of 1,500 h. p. and two engines of 10,000 h. p., driving Ferranti 10,000-volt alternate-current dynamos for transmission of current through mains to London, and transformation there to currents of

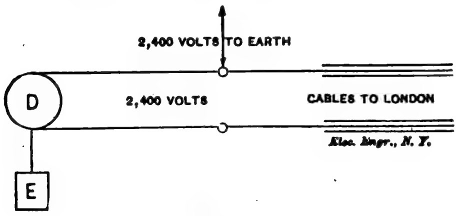


FIG. 1.

2,400 volts, as for some years distributed from the Grosvenor Gallery. Of these engines, one of the 1,500 h. p. engines is erected and has been running since November, last year. This is the only engine running at Deptford at present. A second one is already erected, but is not yet used for supply, and two 10,000 h. p. dynamos are in course of construction, and parts of the immense 42ft. flywheels, the 27-ton shaft, and the huge cranks are being turned up in machine tools erected inside the station.

It will be remembered that the Ferranti concentric mains not being ready, the company laid and ran from Deptford to Charing Cross temporary cables of special manufacture. These, however, were found to be unable to stand the high pressure of 10,000 volts, and a reduction to 2,500 was made, the inner conductors only of the two cables being used.

At this pressure current was transmitted for some time from Deptford to the Grosvenor, where it was used together with the current from the Grosvenor dynamos. The arrangement under these conditions is shown in the diagram, Fig. 1. It is hardly necessary to remark that such an arrangement reduced by half the output that could be transmitted at even the half pressure before used of 5,000 volts, and at this lower pressure the whole lighting of the present installation of 38,000 lamps could not be supplied from Deptford.

An ingenious arrangement was therefore adopted and has been running for some weeks, by which, though the

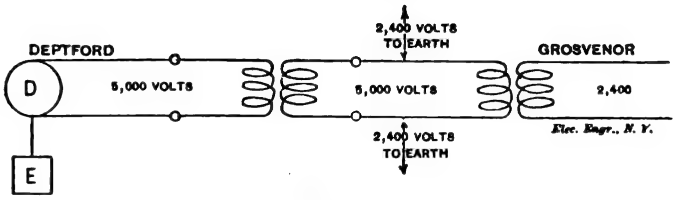

FIG. 2.

pressure to earth from the cables is only 2,400 volts, yet the total pressure of the current transmitted is 5,000 volts, under which conditions the whole lighting can be, and has been, done from Deptford, the Grosvenor acting merely as reserve. This arrangement, which will doubtless greatly interest our readers, is shown in diagram in Fig. 2. The Deptford dynamo is run at 5,000 to 6,000 volts, and one pole of the dynamo is put to earth. But instead of transmitting direct to the Grosvenor, the current is put through transformers *at Deptford*, transformed and transmitted to

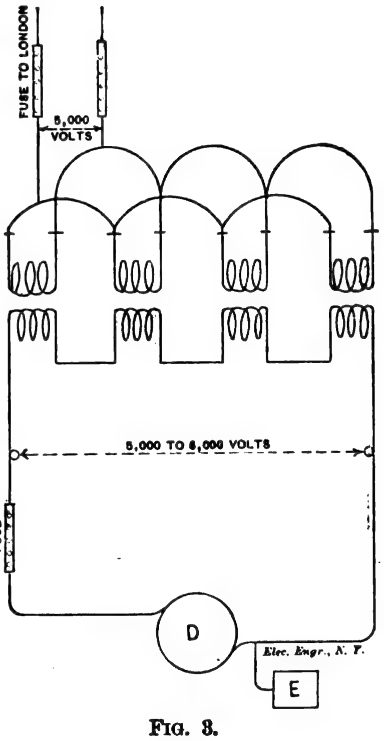

FIG. 3.

London still at 5,000 to 6,000 volts. Now, as will be seen by the diagram, though the total pressure between the mains is 5,000 volts or more, the difference of potential between each of the cables and earth (the insulation being kept the same in both) is exactly what it was before in the case of one only—viz., 2,400 or 2,500 volts. In this manner the danger of sparking to earth is overcome, and double the energy is transmitted.

The exact arrangement of the transformers is indicated in diagram Fig. 3. Four transformers are arranged with

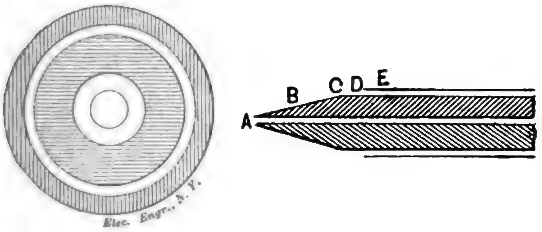
---

1. London *Electrical Engineer.*

their low-tension coils in series in the dynamo circuit with a high-tension fuse on one pole, and the other dynamo pole being put to earth. On the other side of the four transformers their poles are connected in parallel, passing through two high-tension fuses, and so into the main cables to London. So that each set of four transformers transforms from 5,000 to 6,000 volts, with three fuses in circuit, and one pole on the dynamo side of the transformer being to earth. Three sets as above are arranged at Deptford, each set with its own main switch and three fuses, so arranged that one, two, or three circuits can be thrown in at will, according to requirements at London as intimated by telephone.

These diagrams are reproduced from those kindly given to us by the company's engineers.

Accurate records are kept from day to day and from



FIGS. 4 AND 5.

hour to hour of the current and pressure registered. The amounts now registered in daily running show currents of from 30 up to 120 amperes at pressures from 5,000 up to 6,000 volts. This, it will be observed, is already nearly two-thirds the pressure of 10,000 volts ultimately intended to be run. The main laid was originally intended for this higher pressure with a loss in transmission of 8 per cent. The current, as at present sent, is at half or two-thirds only of this, and, of course, the loss in transmission is naturally somewhat higher at the lower pressure. But it

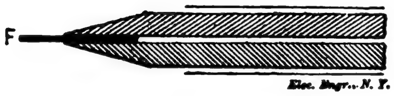


FIG. 6.

is interesting to note that, notwithstanding this extra loss at present, the actual cost of manufacture per unit delivered at London from Deptford is stated by the engineers to be considerably less than the cost of manufacture at the Grosvenor.

For the manufacture of the Ferranti concentric mains special machinery has been erected at Deptford, and is now in full working order. Some two miles or so of main are

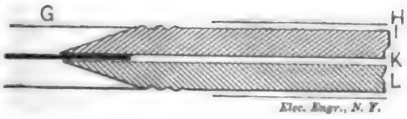

FIG. 7.

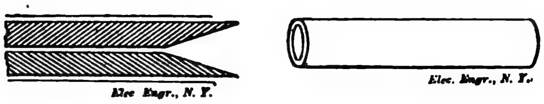
now being turned out every week, and on our visit we were shown the entire process from beginning to end.

The main is of section shown in Fig. 4; first, a small thick hollow tube of copper; then the main insulation; over this the outer hollow conductor of thin copper tube; then another thin coating of insulation; and, lastly, a steel outer casing for prevention of mechanical injury.

The first process is that of insulating the inner conductor. Copper tube of the required section (¼ square inch area) and size is cut off by a circular saw to a length of 20ft. This is taken to a long tressel and long strips of brown paper, 20ft. long and some 4ft. wide, are gummed at one edge to the copper tube. This is now taken to the covering machine. This insulating or covering machine has been specially designed and adopted for the manufacture of these mains, and works with great ease and simplicity. At one side another machine prepares specially coated paper. This machine is nothing more than a long hot-plate, coke-heated almost to the scorching point, over which long strips of brown paper, from huge rolls like that



FIGS. 8 AND 9.

used in printing newspapers, are drawn by rollers. On the hot-plate all moisture is driven out, and the strip of paper then passes down, into, and through a hot cauldron of special black oil or wax, coming out soaked in this wax, and is then dried and cut off into 20ft. lengths. These lengths are carried to the insulating machine first mentioned, and laid in heaps underneath a long metal table in front of this machine. The copper tube is slowly rotated, and six or seven sheets are then wound on till the inner tube is covered as thickly and tightly as possible.

The next process consists simply in slipping this 20ft. length of insulated tube into a second hollow tube of thin copper, which forms the outer conductor, and which is of corresponding total section to the smaller and thicker inner

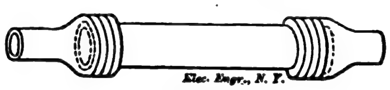


FIG. 10.

one. Then the whole is passed through a large draw plate, and the outer tube is carefully drawn down tightly over the insulation.

Next, the insulating process is repeated on the larger conductor—gummed brown paper, inserted sheets of prepared waxed paper, hot wax bath, rolling, and taping.

Finally, the first stage of the manufacture is completed by slipping on the exterior protective casing of thin steel tube. In this steel tube a small hole is drilled in the center previously, and through this hole hot wax or bitumen is forced in by a force pump, driving out all air at both ends, and forming a compact and solid mass.

Next comes the most important and interesting part of the manufacture of the Ferranti mains, the construction of the joints. When we remember that some six or seven miles of this cable are to be laid in each main; that three mains will be laid from Deptford to London at once, and

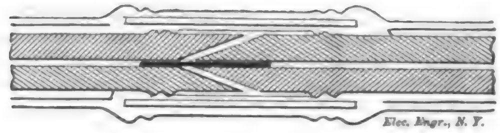

FIG. 11.

that a joint comes every 20ft., it is evident that the joint is the point at which greatest care must be taken to have perfect insulation and perfect protection against creeping or sparking of the 10,000-volt current.

The joint is made in the following neat and simple way: First, the cable, as manufactured in lengths, is taken to specially adapted turning lathes. There one end of the main is turned carefully and smoothly down in a taper of 6in. length, from the centre conducting tube backwards to the outer conducting tube, as shown in Fig. 5. This turning is carefully and accurately done to gauge, and by tools set at the required angle, and is polished off to a smooth surface.

The interior of the inner copper conductor is accurately bored out and smoothed; and then a length, some 18in. or so, of turned solid copper rod is forced into this, a tight

metallic fit, as in Fig. 6. Then a sleeve of thin copper tube, slightly larger than the outer conductor, is slipped over the end of this outer conductor, left bare for several inches for the purpose, and is there corrugated down upon it with three corrugations, as shown in Fig. 7. This corrugation is an essential part of the construction of the Ferranti main, and is a neat, simple, and effective method of securing both good metallic contact and strong mechanical juncture. The method of corrugating on is carried out with a smooth polished steel wheel and grip, and it is used, as will be seen, several times in the making of the joint. This finishes one end of the length. The end is filled up

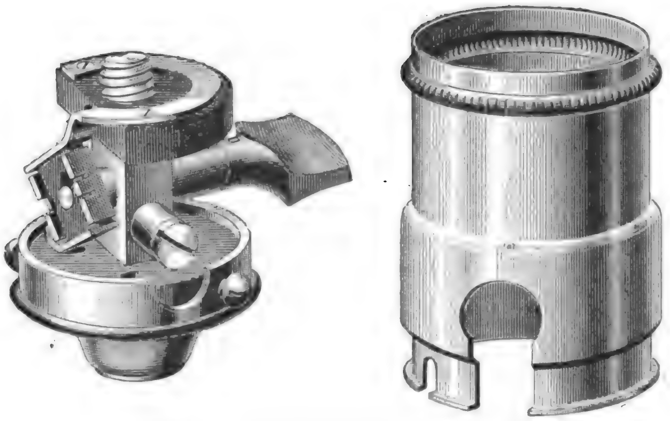

FIG. 1.—THE "H. G." KEY SOCKET.

with a piece of greased waste, and capped with a tin cap ready for transport by railway.

The other end is treated in a corresponding way to form an exactly opposite contour, into which the end of the next length can be pushed tightly. The insulation here is turned out in a hollow coned or taper form from the exterior inward for the length of 6in., as shown in Fig. 8. This turning is also carefully done with tools set at the required angle and smoothed or polished, and the ends meant to join are tested together to see that they fit.

The main is now ready for actual jointing. In making the joint the ends are pushed together, the solid inner rod, which projects from one end of each length, going into the interior of the inner conductor of the next length. Previously to the jointing, a joint-cover, composed of two pieces, Figs. 9 and 10, is slipped some distance back over the main. This joint-cover comprises a sleeve or tube of waxed paper insulating material, and a length of steel tubing formed like a reducing junction, as shown in the figure. To make the joint the ends are pushed together as mentioned, and then are forced together by hydraulic pressure till tight home. The joint is now heated, and the smooth taper surfaces of the joint stick together. After this the copper sleeve, which has now slipped forward over the joint, is corrugated down in the manner before explained upon the other side of the main outer conductor. thus forming metallic connection with this outer conductor, When this is accomplished the paper insulating sleeve, with the exterior steel protecting piece, Fig. 10, are slipped forward over the joint. Hot wax or bitumen is forced in to fill up the space, and finally each end of this steel jointing piece is corrugated down upon the steel protecting tube of the main itself, so forming a compact solid joint.

Thus the joints are made. About two-thirds of a mile of this main has been laid and practically tested since April 19. Pressure of 16,000 volts to 18,500 volts have been kept on this length, at intervals as the dynamo has been running, ever since. Since then fresh lengths have been added from time to time, each length being tested as it was put on with 18,500 volts. No breakdown whatever has occurred, even in testing. The actual working current has not actually been passed through at this pressure, owing to the evident difficulty of getting rid of, or absorbing, this enormous energy. But this length of main has been tested with 400 amperes of current at a low pressure, and immediately after this test the full testing pressure of 18,000 volts was turned on with equally satisfactory results. One part of the main, where it entered the Deptford works, has been twisted and bent into wavelike form to show that bending can be done without damage to the cable ; and also to test this method of allowing for expansion without the necessity for special expansion joints. We shall await with impatience the actual working of these mains to London, but it will be seen that the particulars we have been able to give show great promise of a satisfactory method of dealing with the enormous tensions with which Mr. Ferranti has associated his name at the Deptford central lighting station.

THE POLARIZATION OF ELECTRODES.

THE maximum polarization which metallic plates acquire when plunged in an electrolyte varies with the temperature ; when silver wires are used the variation is very regular, and tends towards zero as the temperature approaches that of the decomposition of the salt. M. L. Poincaré has investigated this matter by changing the nature of the electrolyte on the one hand and on the other by using electrodes of different metals. With different electrolytes it is stated that the polarization of the silver is nil at the temperature of decomposition. In substituting wires of gold or iron for those of silver the polarization has not the same regularity, but the final result is the same. It is therefore concluded from the experiments of M. Poincaré that the polarization of electrodes is nil at the temperature of the decomposition of the electrolyte.

A NEW INCANDESCENT LAMP SOCKET.

In the accompanying engravings we illustrate a new incandescent lamp socket invented by Messrs. A. B. Holmes and G. T. Gale, and known as the "H. G." socket. This socket, which is manufactured by the Consolidated Electric Manufacturing Company, of Boston, is extremely simple in construction and is said to contain fewer parts than those generally in use. The electrical and mechanical features have also been well worked out.

In the key socket, shown in Figs. 1 and 2, the contact springs are of phosphor bronze. They are broad and are cleaned by the working of the key in turning the light

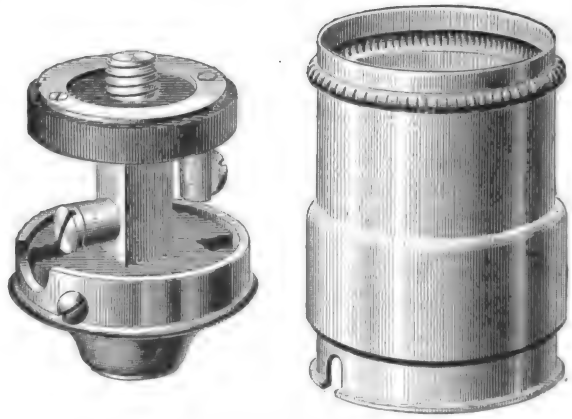

FIG. 2.—THE "H. G." KEYLESS SOCKET.

either on or off. The springs are of ample carrying capacity and make perfect contact with the connecting block. In a test lately made at the factory of the company the socket was used as a switch and would make and break the circuit carrying current for twenty-six 16 c. p. 90 volt lamps, without heating.

It will be noticed that the key is constructed so as to give a double break, thus ensuring an absolute rupture of the circuit.

The engravings, Figs. 3 and 4, illustrate the new keyless socket manufactured by the same company, which is so simple as to require no further description.

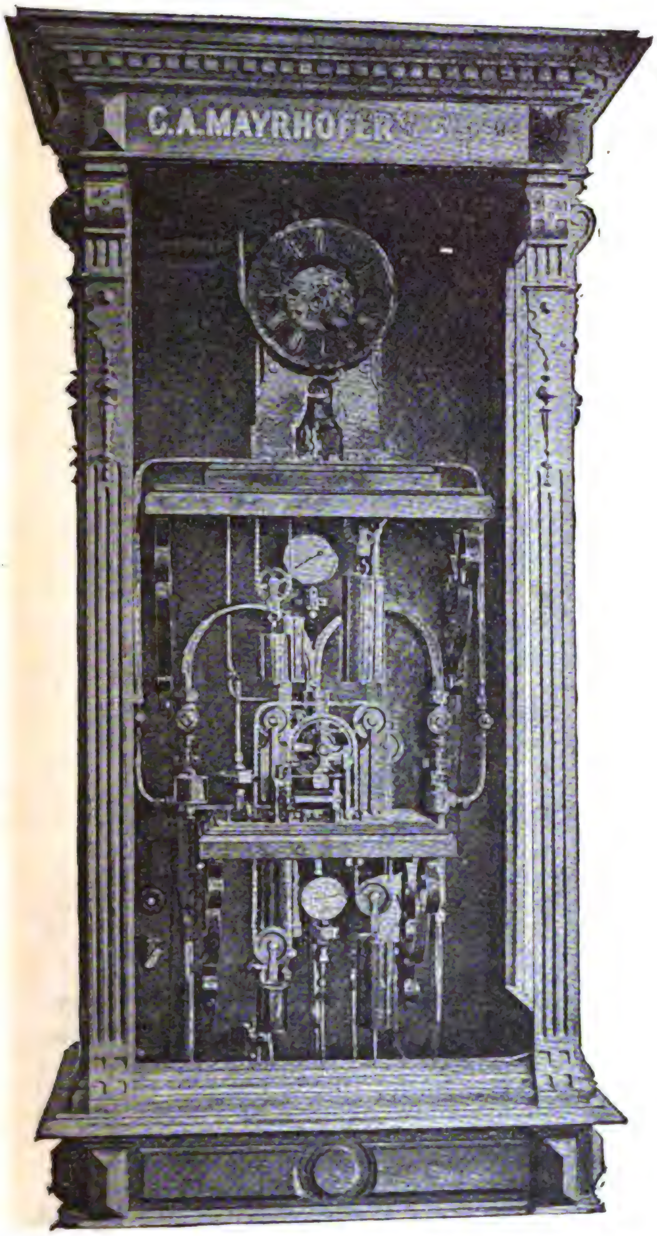
THE MAYRHOFER ELECTRO-PNEUMATIC TIME SYSTEM.

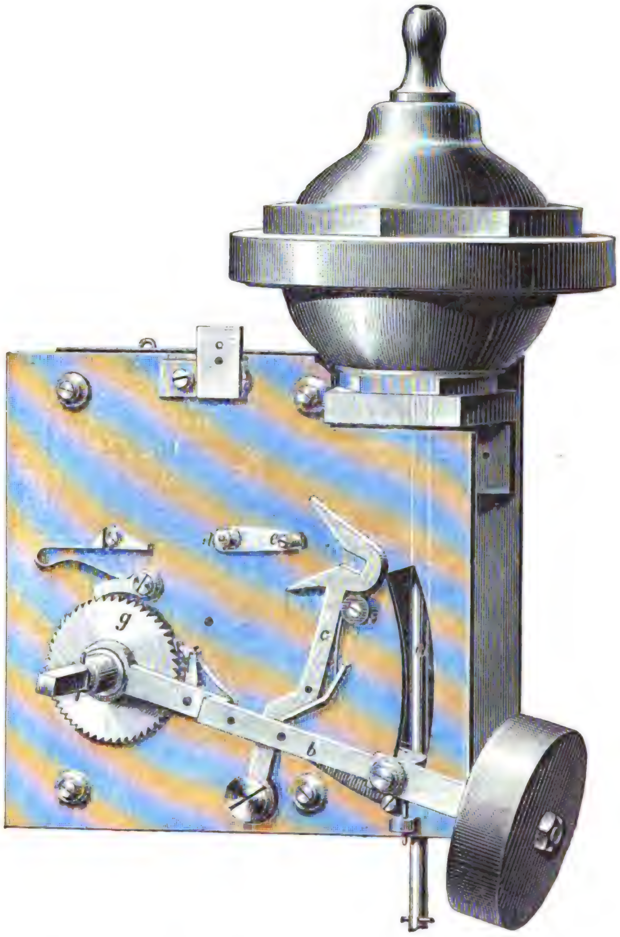
The distribution of accurate time over a large area has long been the subject of study, and not a few inventions have been the outcome of the desire to accomplish this result. The adaptability of electricity for this purpose seems obvious, and it has been employed in various ways. But we desire now to bring before our readers a system in which electricity is combined with a pneumatic system in which the results obtained have thus far proved highly satisfactory. This system, known as the Mayrhofer electro-pneumatic system for distributing standard time, is now being introduced in this city, having been in use a number of years abroad with eminent success. The system consists of a central apparatus with a master clock, or regulator, and a series of secondary clocks which are connected with the central apparatus by a system of tubing. Our illustration, Fig. 1, shows the central apparatus and the master clock.

The master-clock or regulator is in electric connection with the central apparatus, and opens at certain intervals of time, say, every half hour or hour, the supply-cock of a main pipe by which water is supplied to ejectors which are connected to the line pipes, and which produce a vacuum in the same, which vacuum is made use of for winding up and setting all the secondary clocks in the system. The connection between the master-clock and the mechanism for opening the supply-cock is made by an electric circuit which is closed at regular intervals, so as to operate an electro-magnet, the armature of which releases the driving mechanism of the supply-cock.

These clocks are each provided with an oscillating lever, *b*, Fig. 2, that is connected by a spindle with a diaphragm, located in a hermetically-closed casing or shell, which is connected to the line-pipe; so that by the lifting of the diaphragm by the vacuum produced in the line-pipes, the actuating lever is raised, and a hand-setting fork *c* operated, which engages a crank-arm *e* on the arbor of the minute-hand, so as to set the hands, while a pawl and ratchet-mechanism, operated by the main lever, winds up the spring or weight of the clock so as to enable it to run in a regular and reliable manner until the next re-winding takes place.

The system is capable of operating 500 secondary clocks from one central apparatus, which can be placed in any portion of the building for which the time service is arranged. The apparatus, it will be noted, is entirely automatic in every respect, and requires no attention whatever, owing to the joint action of the electric, hydraulic, and pneumatic forces. The clocks being of the ordinary construction it is evident that if, for any reason, the water supply should fail or an accidental break in one of the small tubes should occur, the secondary clock will continue to run until the cause of the accident is removed and the defect repaired. This system, we may add, has been successfully introduced into a number of public buildings in Vienna, in the new Stock Exchange, and the Potsdam railway station and other buildings in Berlin. We may say that the full plant is in working operation in Aldrich Court in this city at the present time, where a large number of secondary clocks are distributed in the offices.



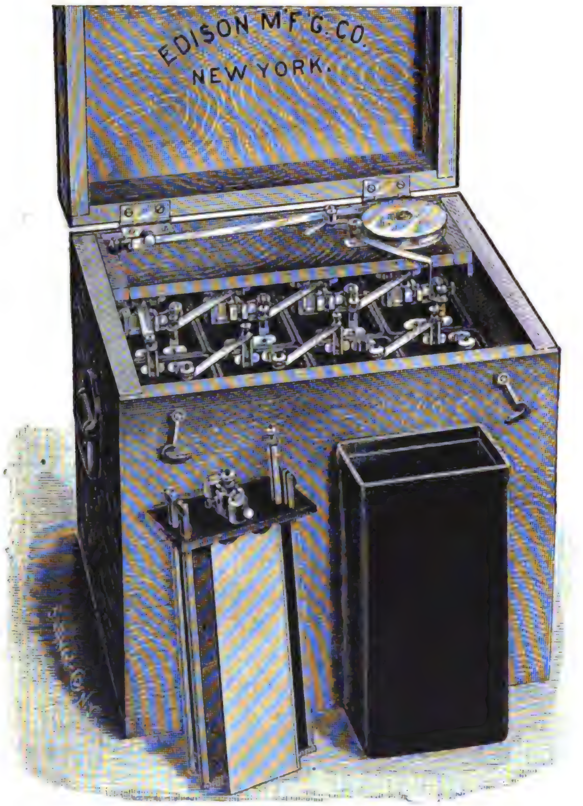


FIGS. 1 AND 2.—THE MAYRHOFER ELECTRO-PNEUMATIC TIME SYSTEM.

THE EDISON—LALANDE BATTERY FOR CAUTERY PURPOSES.

The use now made by physicians and surgeons of electric current and electric appliances is so extensive as to warrant special effort in adapting apparatus to their necessities, especially where it is evident that a number of advantages can be gained. Such is the case with the Edison-Lalande Battery which has now been brought out in a form that renders it peculiarly suitable as part of a medical cabinet or outfit. In this battery, it will be remembered, the elements employed are zinc as the positive and the black oxide of copper as the negative, the exciting liquid being a solution of caustic potash. The chief qualities of the cell are its low internal resistance and its great constancy, rendering it available equally for both open and closed circuit work.

The cell is made in various sizes, and 8 of these cells are taken and put together in hard rubber cases in a neat oak box standing 16½ x 15½ x 13 in. In this shape the battery is very handy and convenient for medical use, answering the requirements of both a portable and a stationary set.



EDISON-LALANDE CAUTERY BATTERY.

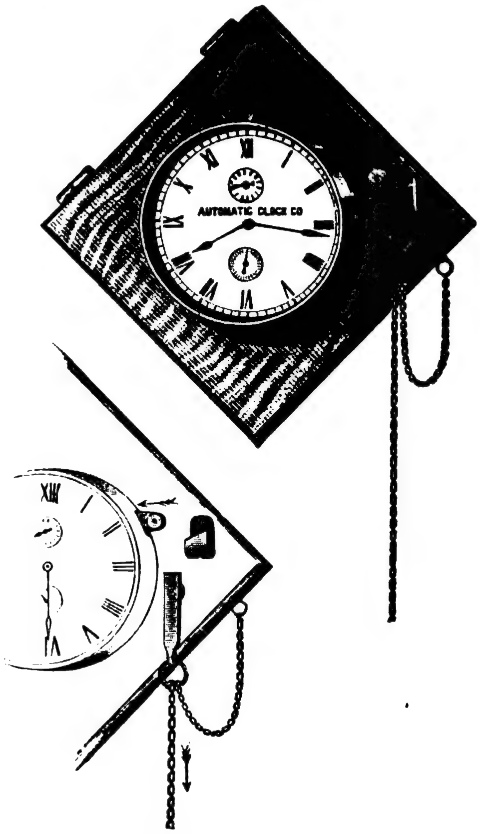
The resistance is included in the outfit, and is placed in a very novel manner in the top of the case, on a little hinged lid that can be thrown up so as to expose all the batteries clearly to view. This resistance is in the shape of metallic tape, and operates after the manner of a fishing reel or ordinary yard measure. It is pulled out to any length as required, and when the needed resistance is obtained is held at that point. As the battery falls off, it can be released and rolled up automatically, either all at once, or gradually.

As is well known the usual cautery knife requires a considerable volume of current to keep it at white heat—say 15 or 20 amperes. This the Edison-Lalande cautery battery will supply steadily for 7 or 8 hours without flagging. Even then it will not be exhausted but will give forth sufficient current to maintain the ordinary cautery made at proper heat for a great many hours.

THE AUTOMATIC SWITCH CLOCK.

In many instances in connection with electrical work it is necessary to switch on current to various devices at a set time, or to break the circuit. Thus in the operation of arc or incandescent lamps in stores usually no provision is made for turning out the lights at the hour of the evening agreed upon in the contract, and it is left either to the consumer, or, more frequently in the case of the arc light, to a lineman who turns out the lamps. But, as station managers know to their cost, the lights are not infrequently allowed to burn all night, for which the company gets no revenue whatever.

In order to get rid of this source of loss and relieve the customer as well as the company of the care of switching off lamps at the proper time, the Automatic Clock Co., of Syracuse, N. Y., have recently brought out a simple and ingenious arrangement which effects this work automatically.



FIGS. 1 AND 2.—AUTOMATIC SWITCH CLOCK.

The apparatus which is illustrated in the accompanying engraving, Fig. 1, consists of an ordinary clock with a small attachment. The motive power for operating the switch consists of a roller with a chain attachment, hung on an inclined track a little to the right of the clock and kept in place by a bar drawn from the clock and resting against the track. At the set time the bar slides into the clock, as shown in Fig. 2, and then, the track being clear, the roller drops, and operates either to open or close a switch, as the case may be.

The uses to which this simple device can be applied must be apparent. It can be employed not only in turning on and off lights but may be used also in connection with motors, etc. Another use for it is found in connection with the regulation of furnaces. Thus it may be so set as to keep the damper of a furnace closed during the night but effect its opening at a fixed time in the morning so as to warm the apartments before the rising of the occupants, and at the same time awaken the servant by closing the switch of an electric bell circuit. Many other uses will suggest themselves to our readers and the clock seems well adopted to afford convenience and effect increased economy in various directions.

THE "UNIVERSAL" ELECTRIC LIGHT FIXTURE SWITCH.

We illustrate on this page the new "Universal" electric light fixture switch just brought out by the Bergmann Electric and Gas Fixture Co., of this city, intended for all kinds of electric light fixtures, and for any system of incandescent lighting. Fig. 1 shows the switch by itself; Fig. 2 shows one manner of applying it, and gives an idea of its internal construction.

Electric light fixtures have been made hitherto without this almost indispensable appliance, and have consequently been inferior to gas fixtures in the important respect of convenience in turning on and off the light. Moreover, the best made and most ornate key sockets of any electric light system are but too often unsightly, and will disfigure the fixtures on which they are used, if these fixtures make any pretensions whatever to design and ornamental character. In fact the application of this "Universal" switch has even opened the way to some new designs hitherto impracticable or unthought of because of its absence. The key socket not being used, and the keyless sockets having been reduced to much smaller and ornamental shapes, a great gain is accomplished in the direction of style and appearance, as well as cheapness, convenience and practical qualities of fixtures.

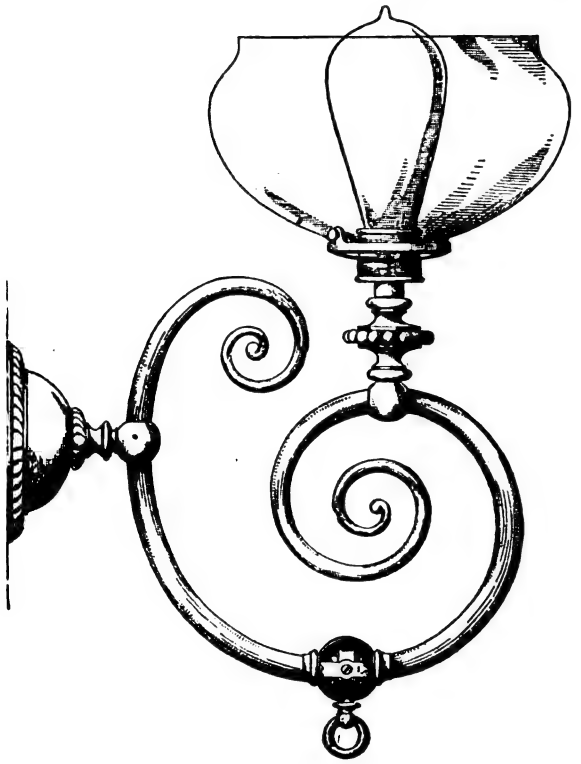


Fig. 2.—Fixture with "Universal" Switch.

To have the key for turning on and off the current in the lamp socket itself, is to have it, in nine cases out of ten, in the most inconvenient and inaccessible position. The lamp socket is generally high up on the fixture, and a special key turner is often necessary, not only because the key is beyond ordinary reach, but because it projects sideways, or at an angle, instead of downward. The tendency at the present time is toward making the lights point upward, as in gas fixtures, and where they point downward to inclose the lamp (and often the socket itself) entirely in the globe. This can only be done in a practical manner by embodying the switch in the fixture itself.

The "Universal" switch will, in most cases of course, be used for but one light, but it will easily do for several. It may be pointed out that the switch and connecting parts are separate from the supporting frame, which can be cemented, soldered or brazed into the fixture, and undergo every process that fixtures are put through during their manufacture, affording at the same time as strong and substantial a support of the parts of the fixture as a regular gas cock. The key shown in Fig. 2 is separable, and other patterns can, of course, be used as desired. The key gives a clean, quick make or break and turns either way.

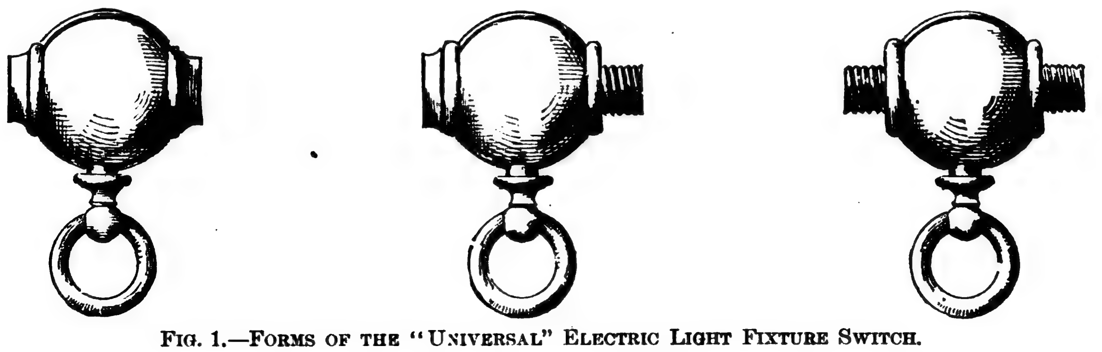

Fig. 1.—Forms of the "Universal" Electric Light Fixture Switch.

THE KOUSMINE DIFFUSION BATTERY.

The diffusion battery of M. Kousmine, which was shown at the recent Galvano-Plastic Exhibition at St. Petersburg, has been much used in Russia. By making use of the phenomenon of diffusion M. Kousmine has succeeded in overcoming the increase in internal resistance of the bichromate of potash battery due to the formation of crystals on the positive electrode. The positive carbon electrode consists of four strips attached to the lid of the battery. The negative zinc electrode consists of a circular grating, resting on the bottom of the battery. By means of a funnel a 15 deg. Beaumé solution of sulphuric acid is introduced, until it just reaches the lower end of the carbon strips. A 6 to 7 per cent. solution of bichromate of potash is next introduced. The two liquids do not mix on account of the great difference in their densities. When the battery is short-circuited it is easy to see that chemical action only takes place close to the lower end of the carbon strips, which are gradually surrounded by a violet ring 2 or 3 millimetres deep. Above this region the bichromate solution retains its original color. The bichromate solution being very weak, the chromic crystals dissolve as soon as they are formed, and the positive electrode is not covered by a deposit, as in other batteries. The solution of these crystals, having a greater density than the surrounding liquid, falls to the bottom. The sulphate of zinc also falls to the bottom of the cell, causing more sulphuric acid to rise. A cell having the following dimensions was tested by a committee of experts at the exhibition in question:—Height, 20 cms.; diameter, 15 cms.; surface of zinc, 176 sq. cms.; bichromate solution, 6 per cent.; sulphuric acid, 15 deg. Beaumé. The committee reported that after having been circuited for 8½ hours on an external resistance of .32 ohm, and then left on open circuit for 10½ hours, the cell continued to work for 4½ hours, when the circuit was again closed, and that it gave during 13 hours 36 ampere hours for an expenditure of 48 grammes of zinc.

THE PORTER AUTOMATIC ENGINE FOR ELECTRIC LIGHTING.

While the well known appliances for keeping down the coal consumption in electric light plants are well recognized, the most important factor, after all, is the steam engine itself. It is in this part of the plant that economy is obtained by the close regulation of the steam consumption to the load on the dynamos, and at the same time economy of operation in the dynamos and outside circuit by maintaining constant speed.

To effect these necessary attributes of a successful electric light plant, the Porter M'f'g. Co., L'td., of Syracuse, N. Y., have designed the automatic engine illustrated in the accompanying engraving, Fig. 1. In this engine special attention has been given to economy, perfect regulation of speed and simplicity and rigidity of parts.

The distribution of steam is effected by a single flat slide valve perfectly balanced with a cover plate, and so arranged that water may escape from the cylinder without injury to the engine.

For the regulation of the engine the Porter company have adopted the wheel governor of the Straight Line Engine Co., designed by Prof. Sweet, which gives perfectly uniform speed under a varying load and steam pressure. As shown in the accompanying engraving, Fig. 2, it consists of a single ball linked to the eccentric and spring, and so located and weighted as to counterbalance the eccentric and its attachment, and it controls the speed of the engine in the following way: When the speed of the engine reaches the point where the centrifugal force of the governor ball overcomes the resistance of the spring, it flies out, and in doing so moves the eccentric nearer the shaft, shortens the travel of the valve and reduces the amount of steam admitted to the engine. The ball is made of malleable iron, cast hollow, and loaded with lead or shot.

Being heavy and being located at a considerable distance from the centre of motion, and running at a high velocity, the ball has great centrifugal force, and requires a strong spring to resist it, thus forming a powerful governor. In the construction of the governor the aim has been to reduce it to the fewest number of pieces and have it balanced, and to make it very strong and free from friction. It takes no more power to run it than it would so much weight added to the fly wheel, and the engine cannot run away from any other cause than the breaking of the governor ball, as the breaking of the spring would stop the engine. A variation of from five to ten revolutions may be effected by putting in or taking out shot from the hollow ball.

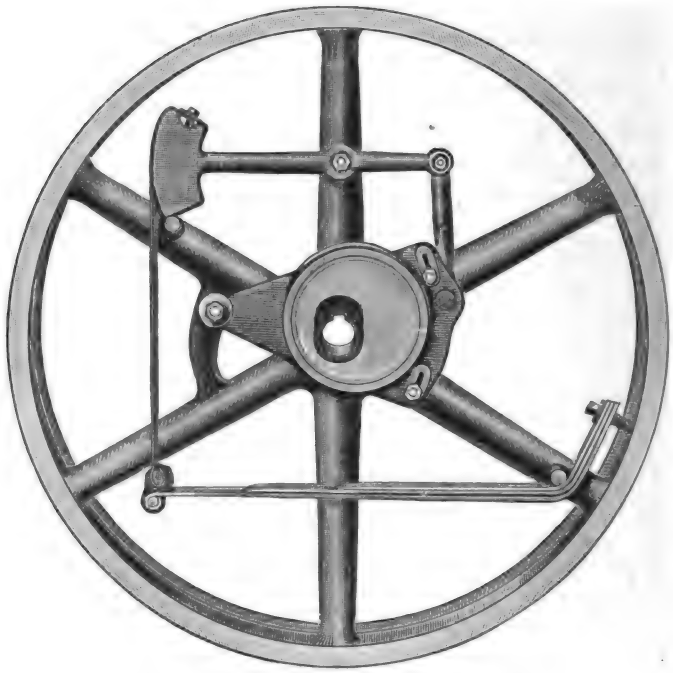

Fig. 2.—Governor of Porter Engine.

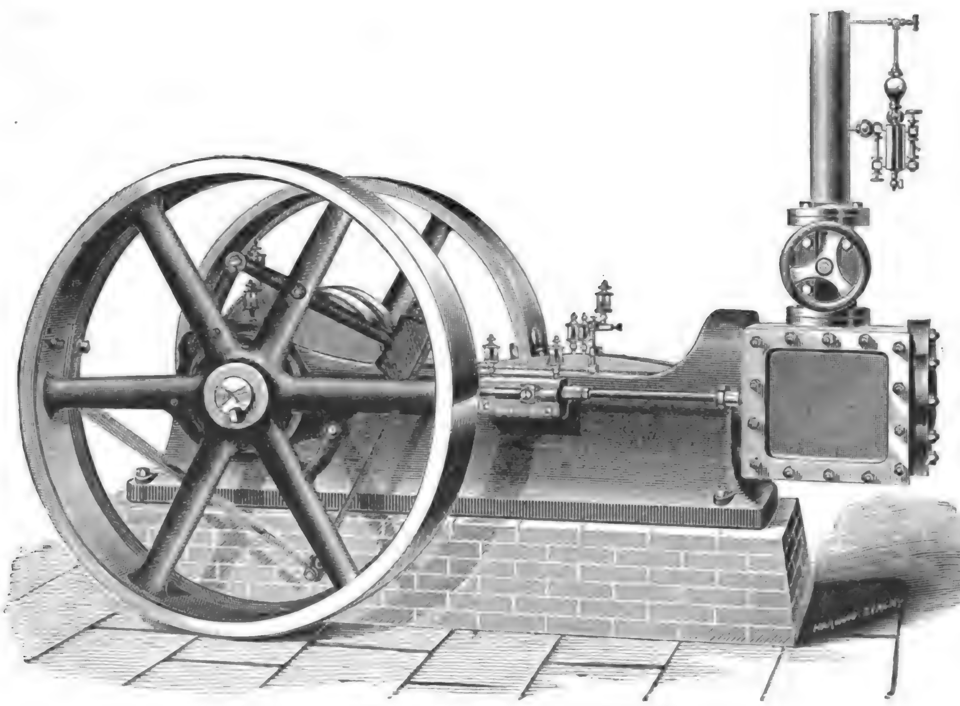

Fig. 1.—The Porter Electric Light Engine.

These engines are at present built in sizes ranging from 23 to 82 h. p., and all designed to run at a speed of 300 revolutions per minute.

The Cause of the Explosion.—In an article on the recent volcanic eruptions at Broadway and Fulton street, the *American Gas Light Journal* says that it is all "because of the infernal recklessness of the Steam Heating Company."

AN EXPERIMENTAL PROOF OF OHM'S LAW—PRECEDED BY A SHORT ACCOUNT OF THE DISCOVERY AND SUBSEQUENT VERIFICATION OF THE LAW.[1]

BY PROF. ALFRED M. MAYER.

I PURPOSE giving in this paper a simple and direct experimental proof of Ohm's law, $\left(C=\frac{E}{R}\right)$. Generally a more formal statement of this law with illustrations are given in text books on Physics, and the student is left to infer that its truth is shown by the cumulative evidence given by the immense number of quantitative relations in electrical actions which the law associates, and by the experience that deductions made on the basis of this law agree in measure with the results of experiments. The latter fact is certainly one of the best proofs of the truth of the law; but, nevertheless, the relations between C, E and R are not directly and simultaneously shown to be exactly expressed by $C=\frac{E}{R}$. It is true that some works give experiments to show this relation, but they are so difficult to perform by reason of the difficulty of maintaining constant C, E and R, that the results of the experiments only approximate to those required by the law.

Ohm was led to the conception of this law by *assuming* that the flow of electricity in a voltaic circuit is similar to the flow of heat by conduction in a rod of indefinite extent. Also, his assumptions that the actions of two electrified particles are directly as their distance and that the electricity is uniformly dense over each cross section of a conducting wire were directly opposed to the laws and facts well established by Coulomb for statical electricity. It is not surprising that scientific men were slow in adopting the views and theory of Ohm. In his memoir (Die galvanische Kette mathematisch bearbitet von Dr. G. S. Ohm: Berlin, 1827) he states:[2] "Three laws, of which the first expresses the mode of distribution of the electricity within one and the same body, the second the mode of dispersion of the electricity in the surrounding atmosphere, and the third the mode of appearance of the electricity at the place of contact of two heterogeneous bodies, form the basis of the entire memoir, and at the same time contain everything that does not lay claim to being completely established. The two latter are purely experimental laws; but the first, from its nature, is, at least partly, theoretical.

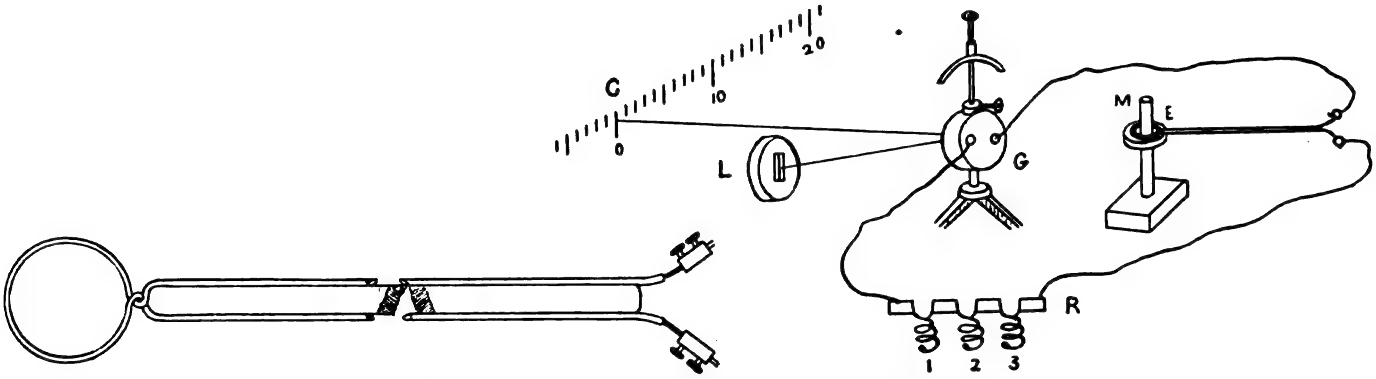
"With regard to this first law, I have started from the supposition that the communication of the electricity from one particle takes place directly only to the one next to it, so that no immediate transition from that particle to any other situate at a greater distance occurs. The magnitude of the transition between two adjacent particles, under otherwise exactly similar circumstances, I have assumed as being proportional to the difference of the electric forces existing in the two particles; just as in the theory of heat, the transition of caloric between two particles is regarded as proportional to the difference of their temperatures. It will thus be seen that I have deviated from the hitherto usual mode of considering molecular actions introduced by Laplace; and I trust the path I have struck into will recommend itself by its generality, simplicity, and clearness, as well as by the light it throws upon the character of former methods.

"With respect to the dispersion of electricity in the atmosphere, I have retained the law deduced from experiments by Coulomb, according to which, the loss of electricity in a body surrounded by air, in a given time, is in proportion to the force of the electricity, and to a coefficient dependent on the nature of the atmosphere. A simple comparison of the circumstances under which Coulomb performed his experiments, with those at present known respecting the propagation of electricity, showed, however, that in galvanic phenomena the influence of the atmosphere may almost always be disregarded. In Coulomb's experiments, for instance, the electricity driven to the surface of the body was engaged in its entire expanse in the process of dispersion in the atmosphere; while in the galvanic circuit the electricity almost constantly passes through the interior of the bodies, and consequently only the smallest portion can enter into mutual action with the air; so that in this case, the dispersion can comparatively be but very inconsiderable. This consequence, deduced from the nature of the circumstances, is confirmed by experiment; in it lies the reason why the second law seldom comes into consideration.

"The mode in which electricity makes its appearance at the place of contact of two different bodies, or the electrical tension of these bodies, I have thus expressed: When dissimilar bodies touch one another, they constantly maintain at the point of contact the same difference between their electroscopic forces (potentials).

"With the help of these three fundamental positions, the conditions to which the propagation of electricity in bodies of any kind and form is subjected may be stated. The form and treatment of the differential equations thus obtained are so similar to those given for the propagation of heat by Fourier and Poisson, that even if there existed no other reasons, we might with perfect justice draw the conclusion that there exists an intimate connection between both natural phenomena; and this relation of identity increases, the further we pursue it. These researches belong to the most difficult in mathematics, and on that account can only gradually obtain general admission; it is therefore a fortunate chance, that in a not unimportant part of the propagation of electricity, in consequence of its peculiar nature, those difficulties almost entirely disappear."

From these premises, and guided by results of experiments made by him and by Ritter, Erman, Jäger, Davy and Becquerel he arrived at the following conditions as existing in a voltaic circuit.



APPARATUS FOR EXPERIMENTAL PROOF OF OHM'S LAW.

1. In a homogeneous conductor, forming part of a voltaic circuit, the difference of the electric tensions at any two points of the conductor is proportional to their distance.
2. In different conductors forming part of a circuit, the difference of tensions at two points separated by an interval equal to the unit of length is in the inverse ratio of the section of the conductor and of its coefficient of conductivity. Hence, in different conductors, equal differences of tension correspond to lengths whose electric resistance is the same.
3. At the point of contact of two different conductors, there is a sudden variation of electric tension.
4. If A equals the sum of the electromotive forces, L the resistances, λ the resistance reckoned from a point m of the circuit to a point p when the tension is zero, the tension at the point m is given by the formula,

$$u=A\frac{\lambda}{L}.$$

Ohm eventually arrives at the formula $S=\frac{A}{L}$, which expresses what is generally known as his law. Which formula, he says, "is generally true, and already reveals the equality of the force of the current at all points of the circuit; in other words it may be thus expressed: The force of the current in a galvanic circuit is directly as the sum of all the tensions, and inversely as the entire reduced length of the circuit, bearing in mind that at present by reduced length is understood the sum of all the quotients obtained by dividing the actual lengths corresponding to the homogeneous parts by the product of the corresponding conductivities and sections."

The words "tension" (*Spannung*) and "electromotive force"

1. *American Journal of Science.*
2. See translation, published in vol. ii, of Taylor's Scientific Memoirs, p. 402, London, 1841.

used by Ohm are the equivalent of the word *potential*. He was the first to introduce this conception into the theory of the voltaic circuit and to the above words and to *current* and *resistance* he attached precise meanings and showed the relations existing between those quantities. The clear definitions Ohm gave of these terms marked a transition from vague ideas of "quantity" and "intensity" to the clear conceptions of potential, electromotive force, current and resistance. The word *energy* he also used with clear and accurate meaning as is shown in the following statement: "That the decomposing force of the circuit is in direct proportion to the energy of the current, and moreover, that it depends on a coefficient, to be derived from the nature of the constituent parts and their chemical equivalents." This was published in 1827, six years before Faraday's researches on electrolysis.

Neither Ohm nor his contemporaries were able to test the truth of the four statements given above as embodying Ohm's theory. It was reserved for Kohlrausch in 1849 to show by very ingenious and accurate experiments that Ohm's statements were true in mode and in measure. Kirchhoff [3] and Quincke [4] applied with success Ohm's theory to the flow of electricity in thin conducting plates, or bodies of two dimensions, and the same was done by Smaasen [5] not only in a plane but in bodies of three dimensions. The most remarkable confirmation of Ohm's law was made in 1876 [6] by experiments, suggested by Maxwell and performed by Chrystal in the Cavendish Laboratory, Cambridge, "in which the testing of this law seems to have been carried to the limit of experimental resources."

Though Ohm's law has thus received such ample verification that it ranks with the best established laws of nature, yet, as Maxwell says, "Ohm's law must, at least at present, be considered a purely empirical one. No attempt to deduce it from pure dynamical principles has as yet been successful. * * * The conduction of electricity through a resisting medium is a process in which part of the energy of an electric current, flowing in a definite direction, is spent in imparting to the molocules of the medium that irregular agitation which we call heat. To calculate from any hypothesis as to the molecular constitution of the medium at what rate the energy of a given current would be spent in this way, would require a far more perfect knowledge of the dynamical theory of bodies than we at present possess. It is only by experiments that we can determine the laws of processes of which we do not understand the dynamical theory."

Surely if an experiment, that is easily made, shows the truth of a law of such theoretical and practical importance as that of Ohm, even if it is one restricted in its range of C, E and R, but shows within its limitations the relations $C=\frac{E}{R}$, then it should be made by all teachers of physics so that clear physical conceptions of those relations may be given to students. As those who have seen these experiments have deemed them worthy of being more generally known, I now publish an account of them.

In the diagram, Fig. 1, the parts of the apparatus are shown, but not at their relative distances apart or in the proper proportions as to size. G is a low-resistance Thomson-galvanometer. At L is the condensing lens of a lime-light lantern, which is covered with a cap having a rectangular opening it. Across the middle of this slit is a vertical wire. The scale of the galvanometer is at C, distant 165cms from the mirror of the galvanometer. The width of the divisions on this scale are 2·5cms, and the lines are drawn 2·5mms in breadth, or $\frac{1}{10}$ the distance apart of the centers of the lines forming a unit of the scale. The scale is at such distance from the galvanometer-mirror that the image of the vertical slit just fits in the space of a scale unit, while the breadth of the image of the vertical wire is exactly equal to the breadth of a scale line. This arrangement gives the means of observing a deflection of the beam of light to $\frac{1}{10}$ and $\frac{1}{20}$ of a unit with quickness and accuracy.

The image of the slit is so bright and that of the wire so distinct that this method of observing deflections of the galvanometer may be used in broad day light and the deflections may be read throughout the room.

An incandescent electric lamp with a part of its surface (behind the plane of its filament) silvered may replace the lime-light. Thanks to this arrangement, I have been able during many years to make before my class electrical measurements, and to measure the radiation, reflection, refraction, diathermancy and polarization of radiant heat.

At M is a magnet 25cms long and 1¼cms in diameter. On this magnet slides a wooden disc. At R is box containing 1, 2 and 3 ohms of resistance, made of coils of copper wire.

An insulated copper wire wound at its middle in a circle of one coil, or in a spiral of any number of coils is placed over the magnet and rests on the top of the wooden disc. Fig. 2 shows (one-half size) how this circle of one coil is made. It is bent around a wooden cylinder 3¼cms in diameter, and then the free ends of wire are bent one-half turn on each other. The free lengths of the wire are then lashed to a light square rod of wood, as shown in figure. The wire and rod are then coated with shellac to cement them firmly together. Rings of spirals of 2, 3, 4, 5 and 6 coils are also made in the same manner, but the coils are in spiral, *i. e.* in one plane, and are then cemented together with shellac between rings of thin card-board.

The length of wire forming each of these rings of spiral coils with the portion on its handle is one meter long.

The resistance of this length of wire added to the resistance of the lengths between it and G and R, together with the resistance of the galvanometer is (for convenience) made one ohm.

It may be well here to speak of the adjustment of the galvanometer before describing the experiments, for I have noticed in some laboratories and lecture rooms galvanometers which are used not as they should be. I have noticed that the damping-magnet formed a considerable angle with the plane of the coil. This was either because the medium plane of the coil was not in the magnetic meridian or because there was considerable torsion in the suspending thread.

In these galvanometers, or, at least, in mine, the median plane of the coil is placed parallel to the faces of the drum of the instrument. The plane of one of these faces is brought in the magnetic meridian of the room, which has been carefully drawn on the table under the vertical center line of the galvanometer coil, by means of a long magnetic needle mounted like those used on plane-tables. A line at right angles to this meridian is now drawn so that its point of intersection with the meridian line shall be exactly under the suspending thread of the mirror. In the vertical plane of the line, drawn at right angles to the meridian, is placed the vertical wire in the slit of the lantern, L, and also the zero line of the scale C. The scale is parallel to the magnetic meridian. The galvanometer is now placed in the position given above and the "directing magnet" removed to a distance. The image of the vertical wire at L will now be found on the zero of the scale if there is no torsion in the suspending thread. If it does not come to zero then the head of the rod to which the thread is attached is turned till image of wire coincides with zero of scale, and then the instrument is in adjustment, and it will give deflections as the tangents of the strength of current, or, in other words, the current strength will be directly as the readings on the scale. The magnet M is now placed so that it causes no movement of beam from the zero of the scale. The directing magnet, above the coil, is now so adjusted that the time of an oscillation of the magnet of the galvanometer is above five seconds.

The coil, E, over the magnet is put in the circuit of G and R. The wires between E and G and R are twisted and tied together so that no induced current from the earth's magnetism may be caused by the motions of this part of the circuit. The image of wire is on zero of scale. Now on rapidly lifting the coil from around the magnet a deflection is produced by the magneto-electric current thus generated. It is sufficient to know that the cause of this current is the quick lifting of the ring with one coil. If we replace this by a ring of two coils we get twice the deflection, and rings of 3, 4, 5 and 6 coils give 3, 4, 5 and 6 times the deflection given by the ring with one coil. Adopting the conception of the lines of magnetic force, we say that the ring with one coil cuts a certain number of these lines, this cutting of the lines causes the current, and is *the electromotive force*. The ring with two coils makes two cuts of these same lines, or, cuts double the number of lines, the rings of 3, 4, 5 and 6 coils cut 3, 4, 5 and 6 times the number of lines and hence give 3, 4, 5 and 6 times the electromotive force.

In these experiments the resistance of the circuit has remained constant. Now take the ring with 5 or 6 coils and let us have one ohm as resistance of circuit. On lifting ring from magnet we get a certain deflection, which we may make exactly equal to a whole number of the units of the scale by sliding up or down the disc on the magnet. We now take out plug of resistance box and make the resistance of the circuit two ohms. The deflection of the galvanometer magnet now becomes one-half of that of previous experiment, and successively making the circuit with resistances of 3, 4, 5, 6 and 7 ohms we get $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{6}$, and $\frac{1}{7}$ of the deflection we got with one ohm in circuit.

When these experiments are made with the galvanometer in perfect adjustment, and with the precautions indicated below, the deflections arrive one after the other exactly as the law requires; thus showing with sufficient precision for a lecture experiment that the current is directly as the electromotive force and inversely as the resistance. Indeed generally the closest scrutiny does not detect in the scale reading any departure from the law.

Certain precautions are, however, necessary in these experiments. The resistance outside the galvanometer must be of copper wire, for such is the wire of the galvanometer. Also, the whole of the apparatus must be put together the day before we make the experiments, and the room maintained at as constant a temperature as possible, so that the temperature of all parts of the apparatus is the same. The deflections should not exceed 15 divisions of the scale. Thus, if we start with 15 divisions of deflec-

4. Pogg. Ann. t. xcvii, 1856.
5. Pogg. Ann. t. lxiv, and t. lxxii.
6. Brit. Assoc. Rept., 1876, p. 36.

tion for a resistance of one ohm we will get 7.5; 5; 3.75; 3; 2.5, and 2.143 deflections for resistances of circuit of 2, 3, 4, 5, 6 and 7 ohms; and if with a constant resistance we obtain a deflection of 2 divisions of scale with a ring of one coil, we will get deflections of 4, 6, 8, 10 and 12, with rings having 2, 3, 4, 5 and 6 coils.

It is necessary that the coils should be removed from the magnet *very quickly*, otherwise the deflections will not be as the law requires. In other words, the currents produced should be as instantaneous as can be obtained. Instead of rapidly removing the coils by the hand, I have sometimes lashed the coil and their handles to a spring-board with a hole in it which went over the magnet. By a trigger this spring-board is released. We thus get the same velocity in lifting the coil in each experiment. We have found, however, that the hand of a good experimenter gives precise results. Sometimes I have sent the coil from the magnet by the blow of a stick delivered on the under side of the handle of the coil at its center of percussion. There is no doubt some departure from the law in these experiments, for it is not possible in such experiments to obtain what is understood by instantaneous currents; and the damping of the magnet by the mirror acting on the air must come into play. Yet I have never seen any but insignificant and barely discernible departures from deflections required by the law. This follows from the small angles of deflections and low velocity of the motion of the galvanometer magnet in the experiments. It is also to be noticed that with a good magnet of the size stated, and with the galvanometer making one vibration in about 5 seconds, the coil with 5 turns passes over only 2 cms., or less, of end of magnet in order that it shall give a deflection of 15 divisions of scale. It is evident that in these conditions a very short time is occupied in cutting the lines of force. If the maximum deflection used is 15 divisions of the scale, the actual angular deflection of the magnets and mirror amounts to only 6°29'. Yet 15 divisions is quite a length on the scale, being equal to 37.5 cms. But these experiments may be as readily made with a ballistic galvanometer. Then the magnets and coils have to be of larger dimensions.

Experiments similar to those given have served to graduate galvanometers. We have here the means of sending definite amounts of currents through an ordinary galvanometer and we may thus graduate its angular reading into their relative values in current. The damping of the galvanometer has, however, to be applied to the readings, and then the results may best be put in the form of a curve.

Stevens Institute of Technology, Hoboken, N. J.

ELECTRIC LIGHTING IN THE RAILROAD SERVICE.[1]

BY M. B. LEONARD,

Superintendent of Telegraph, Chesapeake and Ohio Railway.

For many years one of the most prolific sources of injury to railroad men and loss to the company has been the switching of cars in the yards at night, with only a hand lantern to indicate the movements required. The engineer, owing to the darkness, was obliged frequently to depend more on luck than otherwise to guide him in handling his engine, the result being often a crushed hand or shoulder for the brakeman, if he escaped being caught between the bumpers; or, the engineer miscalculating his distance in the darkness, would come back too hard, and thereby break the drawheads, and smash in the ends of the cars.

The introduction of the arc light in the large yards where a great deal of switching or making up of trains at night is performed, was found, as had been expected, to work a wonderful improvement in this direction, and the use of the arc light for this purpose is now so widely extended, that there is scarcely a railroad from the Atlantic to the Pacific, which does not use the electric light in its important yards.

An extended inquiry among the men using these lights develops the general belief that they pay for themselves several times over in the single item of repairs saved to rolling stock, by enabling the engineers to do the switching more carefully, and with less damage to the cars. These arguments seem strong enough to warrant the use of electricity for this service, whereever the business is large enough to require night work. Other important features in the use of the electric arc lamp, are the greater amount of loading or unloading of cars that can be carried on at night, than with the oil lamp system, and the reduction of the number of car robberies and shortages in freight packages.

The experience of the Chesapeake and Ohio Railway Company at its Newport News, Va., terminus, affords an excellent illustration of the benefits of the electric light in these respects. Through its connections with the Old Dominion Steamship line from New York, large quantities of freight are transferred to cars at Newport News for western points. As the New York steamers arrive at night generally, it is important that the freight be at once loaded, billed and forwarded with the utmost dispatch. Under the old oil lamp system it was found impossible to get the freight billed and cars loaded and started within less than twelve to fourteen hours after the steamer's arrival. The number of claims for shortage and damage were very great, and reports of freight astray were numerous.

In the hope that this condition of things might be improved, a fifty arc light plant was put up, and the piers illuminated by electricity. Immediately a new order of things prevailed; freight was billed and loaded correctly; there being no dark corners, the shortages and damage claims began at once to diminish, and the trains were forwarded in nearly one-half of the time it formerly required, while a substantial rebate was made by the insurance companies from the premium hitherto paid, which offset not a little of the cost of the electric plant, and the reduction of the premium goes far towards paying the cost of maintenance and operation at present.

The lighting was extended to the immense coal piers of the company, and the coaling of steamships, which up to that time could be done very slowly, and only at great hazard during the night, was rendered almost as easy as in day-light. It is therefore safe to say that the Chesapeake and Ohio are satisfied with their investment, and that their experience is not exceptional, is evinced by the fact of the Pennsylvania Railroad Company using no less than eighty arc lights on its coal wharves, yards, engine houses and depots in the city of Philadelphia.

While arc lights are usually designated as of 1,200 or 2,000 c. p., experience has shown that an arc lamp will give more light in some directions than others, and that while the use of globes very much diminished the intensity of the light, in certain cases they distributed it very much better.

For these reasons it is very difficult to determine just how many lights are necessary to illuminate a certain amount of space; frequently, therefore, the best results could only be determined by a number of trials of the lamps in designated positions, changing them about until the desired results are obtained.

A series of experiments, outlined in the *Railroad Gazette*, were recently instituted in Germany to ascertain the candle power of arc lamps, in which it was found that in a Siemens differential lamp, supplied with a current of 14 to 15 amperes at from 48 to 52 volts, the horizontal intensity was about 196 candles (German, very nearly the same as the English); it increased rapidly to about 20 degrees below the horizontal, where it was 1,150 candles, then more slowly until it reached a maximum at about 42 degrees below the horizontal plane, where the light was 2,014 candles; it then began to sink rapidly until below 60 degrees there was no light, but only shadow. The average intensity was 1,228 candles, with the globes on; the actual light obtained, ranged from 510 candles downward to 1,183 in a direction inclined 40 degrees below the horizontal, with an average illuminating power of 834 candles when freshly whitened reflectors were used.

In this country the best results seem to be obtained from the 10 ampere long arc, or from 40 to 50 volt lamps set on poles 35 feet high, and from four to six hundred feet apart. The clear glass globes give the best illumination, as but few of the light rays are absorbed by the glass, but it is found that the unshaded glare of the arc is very trying to the eyes of the trainmen, and consequently the half ground globes are preferred.

In examining the systems used, it is found that the Thomson-Houston and the Brush are most preferred, though the Western Electric and the Jenney are very popular in the West, while the new alternating system of arc lighting of the Westinghouse Company, owing to the greater life of the carbon, is making rapid strides.

A new and important improvement has recently been made in arc lamps which results in an enormous increase in the luminosity of the arc, and consequently a most brilliant and economical light. This has been effected by making the lower carbon hollow and fitting it with a reservoir of oil and a wick; the oil ascending the wick by capillary attraction is converted into carbon vapor by the heat of the electric arc re-inforcing the light of the arc by luminous particles of incandescent carbon, thereby increasing its brilliancy. The tests of this lamp recently made by Dr. Hopkinson, of London, show that the efficiency of the arc in watts per candle is nearly doubled, the color of the light being changed to a clear yellowish white, while the increased cost of the hollow carbon and the oil is so small that it is not worth mentioning—a single drop of the oil lasting nearly a minute. It is claimed for this new lamp that it reduces the cost of arc lighting to such an extent that it is equal to gas at ten cents per 1000 feet. Very little or no alteration is required to utilize this improvement in the present styles of arc lamps, and it is confidently expected that its adoption will soon become universal.

ELECTRIC LOCOMOTIVE HEAD-LIGHTS.

In still another direction the arc lamp will probably prove of great value to the transportation departments of our railroads. For several years experiments have been carried on with the view to adapting the arc light for use in the head-lights of locomotives. It was quickly ascertained, however, that the constant vibration of the locomotive seriously affected the feeding mechanism of the lamp, and consequently the brilliancy of the arc;

1. Abstract of a paper read at the 9th Annual Meeting of the Association of Railway Telegraph Superintendents, Niagara Falls, N. Y., June 19, 1890.

but recently the improved feed apparatus and the adoption of a copper negative pencil, instead of the carbon hitherto used, have been found to eliminate the difficulties, and the National Electric Locomotive Head-Light Company of Indianapolis is now ready to furnish head-lights of this description, the current being generated by a small combined dynamo and engine, carried on the locomotive. The engine is about three horse-power and has four cylinders; with the dynamo, which is about 2000 watts capacity, it weighs about 700 pounds, and is placed over the smoke arch of the locomotive between the head-light and the smoke-stack.

The trials of this apparatus made last November on the Vandalia line showed that on very dark and rainy nights, the fences to the cattle guards could be seen three-quarters of a mile away; a light-colored car would show as an obstruction on the track at about that distance, while one of dark color would not plainly be seen more than half a mile off; twelve telegraph poles would be plainly visible, while a white mile post would appear as a spot of light half a mile away. At 800 feet a tie at the side of the track would be plainly shown. Horses and cattle would show up clearly 1000 feet ahead, and the colors on a switch target could be seen a quarter of a mile distant.

This shows that any serious obstruction on the track, except in case of very thick fog, could be plainly distinguished far enough ahead to stop an air-braked train travelling at a speed of 45 miles per hour, while at a reduced rate of speed during heavy storms and freshets, the liability of running into open draws, or into trestles or bridges carried away by high water would be greatly reduced.

Another method has been experimented with to some extent, in which groups of incandescent lamps are placed in the head-light; this has given good results, but the beam of light is not as penetrating as when the arc is used, and the carbon filaments in the lamps are soon broken on account of the vibration of the locomotive.

THE ELECTRIC LIGHT IN SWITCH STANDS.

On May 30th, 1887, the Southern Pacific Railway Company, owning and operating its own electric light plant at Oakland, Cal., comprising a horizontal slide valve engine, locomotive boiler, and a 65-light, 10 ampere Brush dynamo, finding it difficult to keep the oil lamps lighted in the interlocking and automatic signals in its yards at that point, on account of the variable draughts sweeping across the bay, decided as an experiment to light twelve of these lamps from its electric light circuit, wiring the lamps in multiple.

So satisfactory were the results, that the number of signals so lighted have been increased gradually until 134 lamps in the interlocking and automatic signals, switchstands, switch lights and signal towers there are now lighted by electricity. Thirty-one of these lamps are in switches and signals that have underground wire connections, sixteen of them light up four signal towers, while the balance are in signals located on posts and connected by overhead wires, all being supplied by the arc light dynamo above referred to.

The signal lamps are 38 volt, and are wired from ten to fifteen in multiple, according to the number of signals within convenient distance to form a group, so reducing the E. M. F., that the lamps use only from 20 to 28 volts pressure, thus lengthening their life and yet giving sufficient amount of light to illuminate the bulls-eye lens of the lantern.

In wiring up the lamps, for the purpose of preventing trouble in case they should break or are burned out, a simple switch is used with paper between the contact points, so that in case a wire leading to a number of lamps is broken, an arc will form at the switch, burn the paper, and thus close the circuit.

In putting up the lamps for the signals, the lamp with its socket is screwed on to a rubber nipple placed in the centre of a wooden base, made the same size as the oil lamp bottom which it displaces, wires passing down through the rubber nipple and in grooves cut in the under side of the base, connect the lamp with binding posts on the corner of the base, which makes a complete and portable device for placing it in almost any style of lantern.

For the signals on posts a tin box or case was designed 7″ x 6″ x 3″ with lens on one or both sides and with wooden bottom made to hinge or screw at one end and fastened by a thumb screw at the other end, secured to the post by a pocket constructed on the narrow side of the case and an iron bracket on the post in the usual manner.

This box is made from one sheet of tin and is soldered tightly together with no openings except a bottom which is closed by the wooden lamp base. If well painted, white inside and green outside, this lamp case will last indefinitely. Where the lamps are most exposed to the assaults of the hoodlums with their little guns and stones, a wire netting of one-fourth inch mesh is fitted over the lens in the form of a pocket open at the top so the glass can be cleaned.

After being placed in position and wires connected, no further care or attention is required beyond occasionally cleaning off the outside of the lens.

The lamp complete, including case, base, lens, socket and lamp, costs about $2 each, as compared with about $5 each for the oil lamp complete, which lasted on an average of only two years. The lamps first installed over three years ago are still in use and have required no other care or attention than renewing the underground wire to two of them.

I am informed by Mr. Slater, the Master of Signals for the Southern Pacific Company, to whom I am indebted for many of these details, that the actual expense for the installation and maintenance of these lights beyond the interest on first cost for wire, lamps and fixtures, etc., is very small, the additional amount of power required for the signal lamps being only about five horse power, though in the system of accounting in use on the Southern Pacific Railway, $90 per month is the proportion charged to the signal lights, out of the total expense for maintenance of the whole system. Of the arc and incandescent lights in use at that point, thirty arcs being required for depot passenger yard and road crossings, with 56 sixteen c. p. multiple series incandescents for depot rooms and offices, and one 65 and one 50 c. p. series incandescent lamp for outside buildings. The total expense including the cost for four attendants, fuel, oil waste, and supplies, repairs, &c.

The division of the expense seems hardly fair, as in the installation of the signal lamps nothing was added to the expense for attendance or repairs to dynamo, engine or boiler, and very little to general supplies. All of these had to be maintained on account of the arc and incandescent lights already in use.

So well satisfied have the Southern Pacific Company become with the results from their electric light plant at Oakland that they have in consideration a larger one there to light the railroad shops, coal yards, ship and lumber yards, freight yards and ferry slips—and are operating electric plants at various other points on their line.

The above mentioned plant seems to be the only one thus far installed on so large a scale, and the results obtained evidence a large economy as against the use of the oil lamp for this purpose, where a railroad company owns and operates its own electric light plant of sufficient capacity to supply the signal lamps. As an illustration, the Central Railroad of New Jersey have 45 interlocking signal lamps at their Jersey City station, which consume five gallons of No. 7 oil daily, at ten cents per gallon, or $15.50 per month, with the two lamp men at $40 and $45 per month; the total expense for the 45 lamps is $100.50 per month, as against $90 for the 134 lamps of the Southern Pacific at Oakland, without considering the cost of breakage, the trouble from lamps blowing or bursting, which is likely to occur at Jersey City.

LIGHTING PASSENGER TRAINS.

In regard to the electric lighting of trains, this subject was so fully treated by Mr. Selden in his admirable paper read at the last meeting of the Association that there is little left for me to add; however, some facts have come to my knowledge that may be of interest in this connection.

In the United States at least the system of lighting from storage batteries, charged at each end of the run, does not appear to increase in popularity. The Boston and Albany railroad, after two and a half years' trial, recently abandoned electricity on the two trains that were so lighted between New York and Boston, and substituted the Pintsch gas system. It is stated that the principal cause of this action was the cutting down of the overhead wires in New York, preventing them from charging the storage batteries at that end of the line, as the cars were not equipped with oil lamps, which could be used during that time, but it is also claimed that considerable trouble was experienced from the lamps frequently breaking, and that the expense of maintenance was too great.

The Pennsylvania Company, however, still continues to light their parlor cars from the storage batteries, using a low voltage lamp.

The Intercolonial Railway of Canada have adopted the accumulator system alone on trains between Halifax and Quebec, and now have more than forty cars fitted up with electric lamps, which are of 16 c. p., and vary from eleven to twenty-two to a car. The accumulators are charged at four different points on the line, running about 500 miles with the one charge, and the results thus far obtained are very satisfactory; but to provide for emergencies oil lamps have been retained in each car.

The combination of dynamo and storage battery first adopted by the Pullman Company is gradually being extended in this country, and is giving great satisfaction in the East and West, but, it appears, at a large expense for maintenance. The Chesapeake and Ohio vestibule train, "Fast Flying Virginian," running between New York and Cincinnati with six cars, is supplied with 118 lamps divided up as follows: Two Pullman, 30 lamps each; dining car, 26; day coach, 16; combination car, 13; and the baggage car, 3. Up to May 1st, 1890, the average cost per lamp for maintenance and renewals was $1.10 per month. Yet where the exhaust steam is utilized for heating the train the cost can be materially decreased.

With this object in view the Chicago, Milwaukee and St. Paul Railway have recently added to their equipment two independent light and heat tenders, which carry their own boilers for steam

heating and for running a Westinghouse automatic engine, attached to a No. 4 Edison compound wound dynamo, supplying the current direct for lighting all the cars in the train, thus doing away with the dynamo on the baggage car and the storage battery combination.

The results have been very favorable, and during more than six months of constant service there has not been a single failure. This company have four trains, embracing about 45 cars, lighted by electricity, and expect to adopt this system of illumination on all of their through trains. A full description of the tender, with drawings and other details of the electrical arrangements, will be found in the *Railroad Gazette* of June 13th, 1890. It is stated that the expense of building and equipping these tenders is not much greater than the cost of the storage battery, dynamo combination, with the expensive wiring required in that system.

It is confidently believed that the cost of lighting trains by electricity in the United States can be greatly reduced by adopting the method so largely used abroad of getting power from the axle.

Mr. Houghton, the telegraph superintendent of the London, Brighton and South Coast Railway, one of the patentees of the system, advises me that there are sixteen trains running on that road which are so lighted, thirteen of them local trains and three express. The speed of the express trains reaches 70 miles an hour, while the locals run from 20 to 60 miles per hour. The express trains are wired for an average of 70 lamps and the others 40; the c. p. of these lamps varies from 8 to 16, according to the speed of the train.

The dynamo furnishing current for these lamps is placed in the baggage car, and has a pulley at each end connected by belts direct with the axles of the car. No intermediate shafting being used, the slack is taken up by loose pulleys that can be pressed upon the belts. The dynamos on these trains have a maximum capacity of 5,000 watts, varying with the speed of the train, which, at 10 miles per hour, gives about 48 volts and 35 amperes, and at 60 miles, 65 volts and 75 amperes. The E. M. F. and current of the dynamo gradually increase with the speed. The brushes are mounted in pairs on a rocking frame so arranged that either set of brushes can be brought in contact with the commutator as required by the direction of the train. In the same car with the dynamo, 22 accumulators, weighing about 4,000 pounds, are placed in parallel with the dynamo for use whenever the train stops. Connected by a belt from the dynamo is a centrifugal governor which joins up the circuit at any desired speed, causing the dynamo to charge the accumulators. When the lamps are not lighted, the governor introduces resistance into the dynamo field reducing the out-put to about 40 amperes, in order not to damage the accumulator plates. When, however, it is necessary to light the lamps, the ynamo generates the full current, of which about 35 amperes pass into the lamps, the balance being stored in the accumulators.

In each lamp circuit a regulator is placed in order to keep the light in the lamps at the same power, regardless of the speed of the train, and to shunt any surplus current into the accumulators, so that 42 volt lamps may be used with a dynamo of any E. M. F., above that voltage without any variation in the light of the lamps.

The connections between the cars are made by coupling two cables together, and when the dynamo runs below a certain speed a cut-out breaks the circuit of the armature, preventing the cells from discharging themselves through it and burning it out. Should the dynamo not furnish enough current for the lamps, the accumulators supply the balance, and in doing so strengthen the field magnets and thereby cause an increase of current in the dynamos. One arrangement of the circuits of these trains, has the field magnets of the dynamo wound with two wires in opposite directions, one of which is in shunt to the armature, as if the dynamo was an ordinary shunt machine; the other is wound in the reverse direction, as if the dynamo were a compound machine, and the accumulators are in series with that wire. The lamps are also in shunt with the armature.

The trains on which this system is used, consist mostly of ten cars, which run solid, that is, are not broken up, and average forty 12 c. p. lamps to a train. By using accumulators in each car however, no difficulty would be found in splitting up the train at various points.

The figures given by Mr. Houghton are as follows:

Total weight of the plant on each train, -	3 tons.
Cost of plant on each train, - - - - -	£400 sterling.
Cost of maintenance per annum, - -	£65 "

The only attention given the trains is at each terminus, where one man inspects the apparatus, oils the pulley bearings, etc., before the train pulls out. One of these trains has been running since December 19th, 1883, without a single failure being reported. During the first eleven months of its use it made 2,352 trips and ran 27,322 miles.

The Midland Railroad of England is running three trains lighted by electricity, and has recently fitted up two others. Two of these are short trains always run solid, and the others main line trains made up at various points. The dynamo is placed in the baggage car and is also driven from the car with about the same electrical arrangements as are used on the London and Brighton road. The short trains have 85 lamps run from one set of storage batteries in the baggage car. On one train the batteries are in series, but on the others in parallel. This seems to be the most satisfactory. 8 c. p. lamps are used on this road, two to each compartment, which can be turned down, and this feature is found to be very convenient to through passengers.

This system of illuminating passenger trains is becoming very popular in England, and it is believed that all such trains on the important roads of the Kingdom will shortly be equipped in this way. The expense as shown by seven years' experience on the London and Brighton road is certainly not greater than where common oil is used, and seems to corroborate the report made by MM. Sartiaux and Weissenbruch, to the International Railroad Congress at Paris, a year or two ago, in which it was stated that for lights of the same candle power, gas supplied by the Pintsch system would cost about 11.3 centimes, and colza oil about 16.9 centimes per lamp hour as against 5.6 centimes for the electric light.

Compared with the practice on American roads, the economy of this method of generating the current, is remarkable. It has been stated, however, by various authorities, that it is impossible to secure even fair results in train lighting in this country where the power is supplied by the car axle, owing to the numerous curves on American roads, around which the wheels will often slide without turning the axle a single revolution, thus seriously damaging belts and armature, and cause constant changes in speed; while English roads are almost always tangents, and a high and constant rate of speed is maintained. The experiments made here some years ago seem to corroborate these statements.

In 1886, or 1887, Mr. Barrett, of Springfield, Mass., fitted up a train on the Connecticut River railroad, to be lighted with electric lamps run from a dynamo, obtaining its power from the car axle. A countershaft was used and a peculiar arrangement of a friction clamp transmitted the power to a pulley on the shaft. This clamp was governed by centrifugal weights balanced by stiff springs. When the dynamo ran at its normal speed, these springs just balanced the friction of the clamp, and there was no slip; any increase of speed then caused the friction to diminish and the pulley slipped upon the shaft until the equilibrium was restored; 24 accumulators were connected with the circuit as a regulator, keeping the lamps lighted when the train stopped, and a centrifugal governor broke the accumulator circuit when the train slackened its speed. The brushes were attached to a rocking arm, or lever, which was tilted by magnets in either direction in accordance with the forward or backward movement of the train.

Owing to the arrangement of the car trucks, it was found very difficult to obtain the proper speed of the dynamo, and after successive trials with belts, ropes and chains, it was finally abandoned. Since that time there have been no further experiments of this character in the United States, but it is stated that such improvements are now being made in the driving gear as will obviate the difficulties heretofore encountered, and that further trials in this direction may be looked for within the next six months.

The electric lighting of trains has been hitherto considered very much as a luxury, but its superiority has been demonstrated in so many ways that it is now being regarded almost as a necessity; yet before it can be generally adopted it must be practicable to light the cars on a large scale, and to maintain the plant on each train in good order without expert assistance; it must also be so simple, and at the same time so durable, that mechanics of ordinary ability can be utilized to make the few repairs it will require; its cost, therefore, must be reasonable as compared with other methods of lighting, and the character of trains on which it is to be used.

From the facts above mentioned, it will be conceded that all of these requirements are filled by the English system of taking power from the car axle; it is, therefore, confidently expected that the well-known ingenuity of our American engineers and inventors will be found sufficient to overcome the obstacles which now prevent us from utilizing in the same way the motion of the trains on our roads.

The successful illumination of the Hoosac tunnel in Massachusetts, by 1,250 incandescent lamps placed 40 feet apart on each of the two tracks, affords a remarkable illustration of the flexibility and superiority of the electric light over other illuminations, and the advantages of the arc and incandescent light for the illumination of our depots, waiting rooms, train sheds and offices are so apparent, and well understood, and their use so extensive, that it is unnecessary to make more than a passing notice of this branch of the subject.

In thus considering the various directions in which the electric current has been adapted for illuminating purposes in the railroad service, one is struck by the extraordinary progress that has been made in the art during a few years, and the enormous possibilities that the future opens up for the utilization of this most wonderful of nature's forces. So much has already been accomplished, and so numerous are the workers in the new field, that before another decade of years has rolled around, steam will have been supplanted by electricity, as the motive power of our railroads, and the locomotive of the future will indeed be the the fiery steed called lightning harnessed and subject to the control of man.

THERMO-CHEMISTRY IN RELATION TO ELECTROMOTIVE FORCE.[1]

BY PROF. J. E. SIEBEL.

The quantitative relations between the chemical changes taking place in a galvanic battery and the quantity of electric power generated by such battery are well understood. The amount of heat generated in the whole circuit is equivalent to the total electric power or volt amperes (electromotive force times current strength), generated by the battery, and also equivalent to the amount of heat which would be produced by the chemical changes going on in a battery had the same not been converted into electric energy. Attempts have also been made to establish relations between the electromotive force and the chemical changes going on in a battery, and, according to Sir Wm. Thomson, the amount of heat corresponding to the chemical changes going on in a battery while one molecule of zinc is dissolved is proportional to the electromotive force of such battery. This, indeed, happens to come out correct in a case of some constant batteries having a depolarizer, but it can readily be seen that it is not generally applicable.

Take, for instance, the case of several elements, each made up of zinc as the electro-positive metal, acidulated water and another more electro-negative metal, say iron, copper, silver, etc. In the case of each of the different elements so formed the electromotive force is a widely different quantity, while the heat equivalent to the chemical changes in the battery, while one molecule of zinc is being dissolved, is the same in all cases, since no chemical changes take place at the negative electrodes.

Considerations of this kind and the conviction (based upon the result of certain deliberations, the drift of which it is not desirable to enlarge upon at present), that definite relations of some kind must exist between the chemical changes in, and the electromotive force of, a battery, have led me to the elaboration of a formula, which I think covers the subject quite satisfactorily. At present I will only consider its application to batteries consisting of two metals and dilute sulphuric acid. The electromotive force of such element is, according to the inferences drawn by me, nearly proportional to the difference of the heat which a molecule of each one of the two metals could evolve by being acted on by dilute sulphuric acid independent of the battery, under favorable conditions.

In order to establish the correctness of this assertion I submit the following table which also will more readily show the import of the rule referred to. The first column in this table gives the names of the various metals, the second column, their electromotive force in juxtaposition to dilute sulphuric acid, expressed in volts. In these figures the electromotive force of zinc may be considered as a number somewhat arbitrarily chosen, yet with reference to it the other figures represent electromotive force as established by Hockin and Taylor. (See *Journ. Tel., Eng. & Elec.*, 1879.) The third column shows the relative amount of heat in calories generated by one molecule of the different metals in being dissolved by dilute sulphuric acid. It is readily seen that the heat evolved increases with the electromotive force evolved in volts, multiplied by 1,000 for each calorie produced by the combination per molecule of the respective metal with sulphuric acid and the elements of water.

	E. M. F. Volts.	Calories.	Ratio.
Potassium	3.560	196,000	0.0180
Sodium	3.460	187,000	0.0185
Zinc	1.580	106,000	0.0140
Cadmium	1.220	89,500	0.0137
Tin	1.050	not determined.	
Lead	1.060	73,800	0.0143
Iron	1.130	87,200	0.0120
Copper	0.580	56,000	0.0104
Silver	0.300	20,400	0.0147
Gold	0.280	not determined.	
Mercury	0.260	" "	
Platinum	0.150	" "	
Carbon	—0.276	—18,500	0.0148

Although the figures in the fourth column are by no means exactly alike, as they should be in accordance with the theory propounded, yet they show plainly enough that a direct quantitative relation exists between the electromotive force and the heat of combination; moreover, it should be considered that it would have been a very easy matter to make them correspond exactly to my theory by substituting the value of some electromotive forces by such as have been obtained by some other observers. Furthermore, it is also to be presumed that other atomic properties do in some measure affect the above relation; indeed, the fluctuations in column four in some measure appear to follow the fluctuations in the atomic volume of the different metals.

So far as the limited amount of observations in regard to electromotive forces and thermo-chemical phenomena have enabled me to go, I find the above relations maintained in batteries composed of other materials than the ones selected above; moreover, the applicability of the law of Sir Wm. Thomson above quoted in regard to certain batteries would seem to be a special case falling under the above generalization.

As stated, the values of the electromotive forces in the second column of the above table are based on the determination made by Hockin and Taylor. They were, however, reduced to zinc not amalgamated. In the case of sodium and potassium the electromotive force had to be corrected also, as a solution of sulphate of zinc was used, instead of dilute sulphuric acid, as in their case. Carbon not being mentioned by them, this item was supplied from the observations of Branly (*Ann. Sc. de l'Ecole Normale*, 2, p. 228, 1873). The thermo-chemical data in the third column was taken from a table in A. Naumann's "Thermochemie," 1882, page 481. The item relating to carbon, representing the heat evolved by carbon in combining with hydrogen, was taken from the same source, page 413, and it is placed in the negative, representing as it does, not an actual change, but a demonstration of an affinity or tendency acting in opposite direction to that of zinc and other more electro-positive metals, the tendency of which is to form oxygen compounds under the circumstances in consideration. It will also be noticed that the relative electromotive forces will not be changed by adding or subtracting the same number in case of each of the figures in the second column, and that by changing these figures in this manner the relations referred to may possibly be brought out more correctly.

Connected with the above subject, at least as regards the theoretical considerations involved in both, is a method of producing refrigeration by means of electricity, planned some time ago. It contemplates the creation of cold in such a manner that the heat abstracted from the medium to be refrigerated is made a source of power, instead of being wasted, as is done in the refrigerating machines of the present. This it is proposed to bring about by the decomposition of water under high pressure by an electric current produced by a dynamo or otherwise. The gases so produced, namely, hydrogen and oxygen, either singly or mixed, are used to propel engines by reason of the energy they possess being under high pressure.

After having done work in this manner and having had their temperature reduced correspondingly, the gases can be used for refrigerating purposes by being carried through the rooms to be cooled. After this the gases, by virtue of their chemical affinity toward each other, still possess sufficient energy to be utilized in the form of electricity or mechanical force for the decomposition of the water. In this manner the power of the engine in which the compressed gases expand and the refrigeration would be clearly gained. This, of course, is speaking theoretically; practically there are, of course, losses of power the extent of which I have not yet undertaken to determine. Theoretically speaking, however, I have been unable to find any great objection to the system proposed, but am very much pleased to have had an opportunity to lay the subject before a body of men, some of whom, doubtless, would be able to point out such difficulties if they really exist.

To caution those who are apt to see an attempt at perpetual motion in the above method, I will distinctly state that the above device is nothing of the kind. It is a system calculated to effect the conversion of low differences of heat potential into mechanical power; but it is not an attempt to create power from nothing, which is the essential of perpetual motion as it is popularly understood. For, although theoretically speaking, such an arrangement would keep in motion forever under ordinary circumstances, after being once set in motion on the above plan, yet it would stop at once if the difference between the temperature of the expanded gases and that of the rooms or tanks to be refrigerated should fall below a certain limit, as might indeed happen in cold weather or in a cold climate.

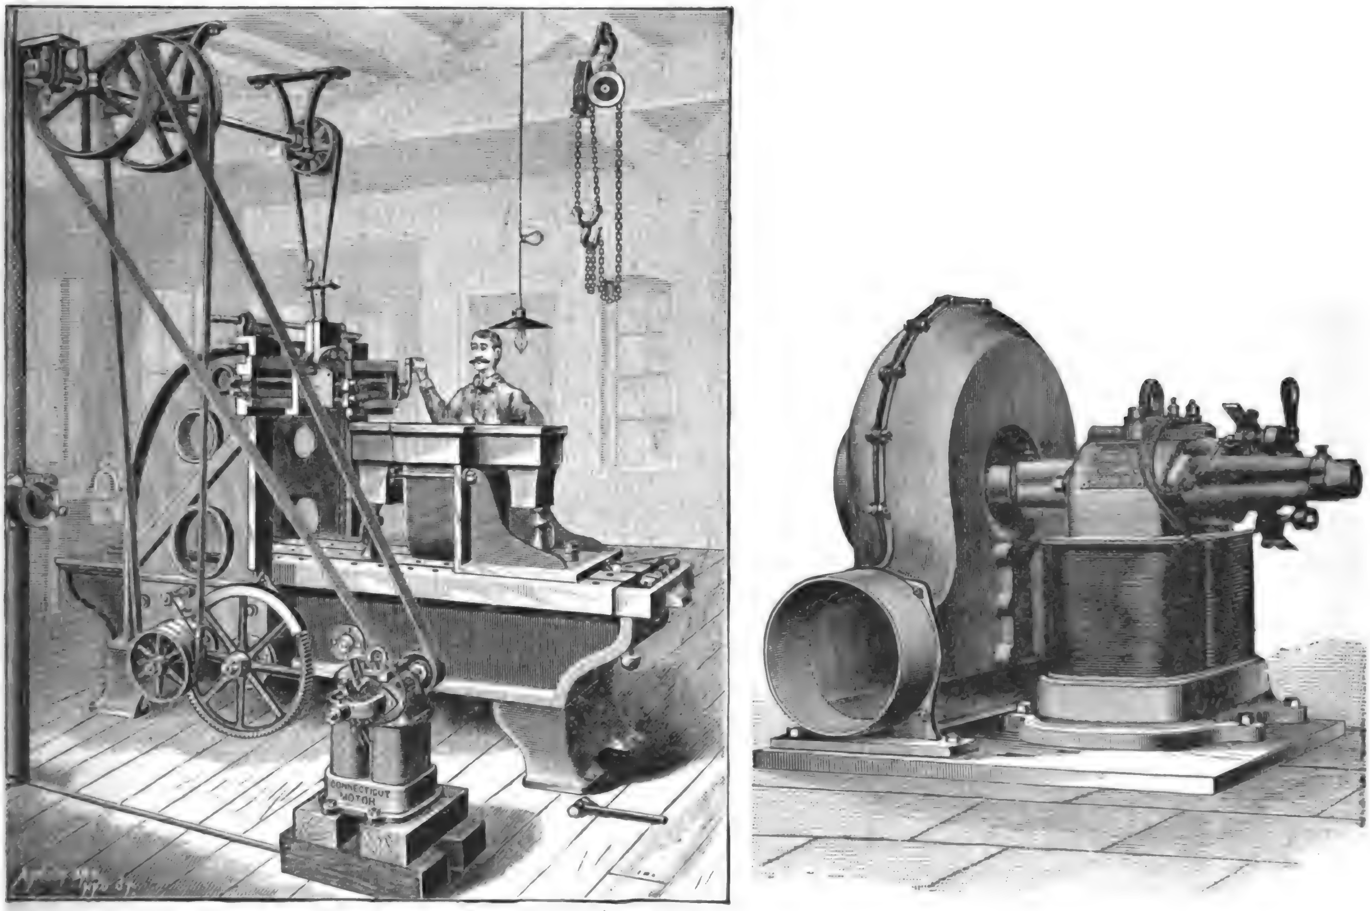
1. Read before the Chicago Electric Club at their second annual meeting, June 27, 1890.

ATMOSPHERIC ELECTRICITY IN THE TROPICS.

In order to investigate the relations of atmospheric electricity to the moisture of the air within certain limits, Herr F. Exner has made observations of the fall of atmospheric potential in countries with high relative moisture, particularly in the Indian Ocean between Aden and Bombay, in Bombay itself, and in Ceylon, both on the coast and in the interior. The measurements were made with transportable apparatus invented by Herr Exner. All the values of the fall of potential were positive. Near the coast the finely-divided spray arising from the breaking of the waves exerted an increased action on the fall of potential. On the other hand, measurements made in Cairo and the vicinity showed that there the dust of the air, exerted a lessening influence on the fall of potential, which, with a strong wind, was so marked that the sign of the fall of potential became negative.

SOME WORK OF THE CONNECTICUT MOTOR.

It may safely be claimed that for nearly all purposes where power is required, the electric motor possesses decided advantages over all other power generators; while in many cases its advantages place it far in advance. Thus there are situations where it is practically impossible to generate power, as in stamp-mills on mountain ledges, drills on quarry faces. Again there are situations where it is inconvenient to generate power, as on draw-bridges, travelling cranes, etc. There are still other situations in which it is frequently unprofitable to generate power, such as small shops requiring a few horse power to drive the machinery, and where a steam engine would entail a disproportionately heavy outlay and continual expense for maintenance. In all these situations the electric motor finds a large field for application and is now being employed.



Figs. 1 and 2.—Connecticut Motor Driving Machine Tools and Blower.

As an example of this we illustrate in the accompanying engraving, Fig. 1, a shop the machinery of which is driven entirely by a motor built by the Connecticut Motor Co., of Plantsville, Conn. Besides the shop shafting, there are eight tools, consisting of drill presses, planers, lathes, blower, etc., consuming all the way from one-quarter up to three and one-quarter horse power.

The engraving, Fig. 2, shows a motor built by the same company and directly connected to a blower.

AMERICAN NAMES FOR ELECTRICAL UNITS.

At the regular monthly meeting of the American Institute of Electrical Engineers, held June 17th, 1890, the following resolution recommended by the council was introduced by Mr. Francis B. Crocker, with the request that it be taken up for action at the next meeting of the Institute in September:

Whereas, it has been the custom in the nomenclature of electrical units to perpetuate the names of men who have contributed most to electrical science; and

Whereas, in the names thus far adopted the eminent services of Americans have not been recognized; therefore

Resolved, that in the opinion of the American Institute of Electrical Engineers, a just distribution of the honors thus bestowed necessitates a recognition of the splendid contributions to electrical science of one or both of America's great electricians, Benjamin Franklin and Joseph Henry; and

Resolved, that this Institute will gladly co-operate with other bodies in this country and abroad to secure the general adoption of these names for electrical units; and

Resolved, that the name of Henry should be given to the practical unit of self-induction, since he was the discoverer and greatest investigator of this phenomenon, and because this unit at the present time is called a quadrant, which is merely a numerical value and not a suitable name.

Resolved, that this Institute recommend to electrical societies and electrical engineers the general use of the name of Henry for the unit of self-induction as being the quickest and surest way to secure its final adoption.

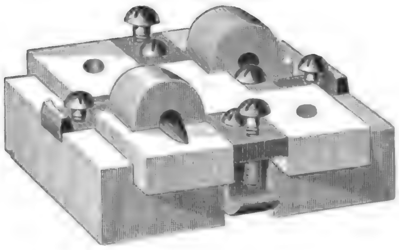
It is unfortunate that the name of Henry for the unit of induction was not adopted at the Paris Electrical Congress of 1889. If the attention of the Congress had been forcibly called to the fact that Henry discovered self-induction and that his work on both self and mutual induction was of the greatest importance, his name would probably have been adopted then. Henry's discovery of self-induction, which is, of course, the fact that gives the strongest claim, was made in 1832 and published the same year in Silliman's Journal. In this paper he describes experiments showing that the spark obtained by breaking a circuit composed of a battery and a long wire is greater than with a short wire, and that the spark is further increased by coiling the wire. He then clearly states that the phenomenon is due to the *action of the current on itself*, all of which is perfectly correct and would be a good statement of the facts even at the present time.

THE EMPIRE CITY SUBWAY COMPANY.

The Empire City Subway Company, Limited, has filed a certificate of incorporation at Albany. The company is formed for general subway work in New York City and elsewhere in the State. The headquarters of the business is in New York, and the capital of the company is $500,000. The incorporators are William T. Bouchelle, John C. Reilly, Union N. Bethell, Hiram F. Stevens and David B. Parker.

THE "CUTTER" BRANCH CUT-OUT.

Among the many specialties which that enterprising new firm, the Great Western Electric Supply Co., is putting on the market, is a branch cut-out with a number of novel features. The cut shows the Cutter branch cut-out complete. It consists of a peculiarly shaped porcelain base and four brass connecting pieces. The brass pieces are set into recesses in the porcelain, two of them clamping a reduced section of the porcelain and all four being firmly held by single screws from below. These screws go in far



The "Cutter" Branch Cut Out.

enough to admit a thick insulating coating between them and the back, so that the block may be safely set against a damp ceiling. The wires are readily fastened without removing any screws. Neither the main nor the branch wires need be cut, but are merely bared opposite the fastenings, and owing to the shape of the porcelain block the main and branch wires can never touch each other. As

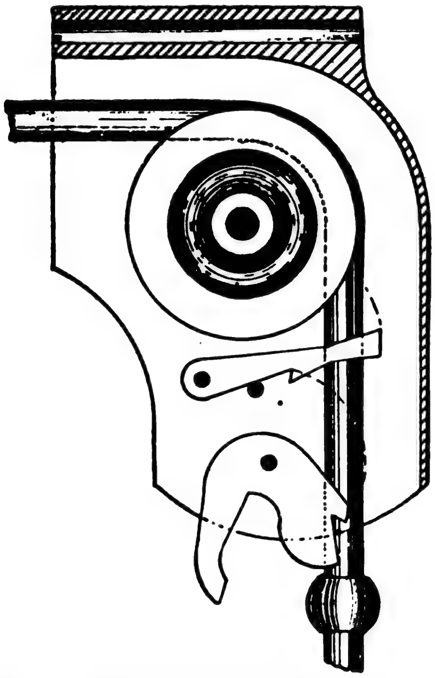


Fig. 1.—Arc Lamp Suspension Pulley.

common screws are used throughout, any lost ones can be readily replaced.

These features will commend themselves, but perhaps a still more novel one is that of a bridge covering the central portion of each fuse. The fuse is easily put in place, and when it burns out the bridge restrains the sputtering and catches the burnt metal. Thus the bridges give the effect of a cover, although fireproof, and are neater and cheaper. The whole is strongly made, nearly twice the size of the cut, and suited for 20 amperes or less.

A NEW ARC LAMP SUSPENSION PULLEY.

Among the numerous new and useful electrical devices which are being brought out by the Great Western Electric Supply Company, of Chicago, is a pulley for suspending arc lamps, which possesses some features of considerable merit. By its use the weight of the lamp is supported by the mechanism in the pulley case, and the hoisting rope is relieved of all strain. Those who have suffered from broken lamps caused by the parting of the hoisting rope will appreciate the advantages of the new device.

The accompanying illustrations show clearly the manner of operation. Fig. 1 shows the position of the parts when the lamp has been raised to nearly its proper elevation.

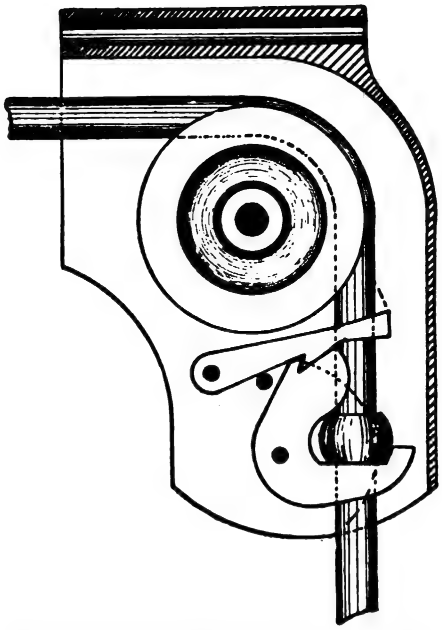

Fig. 2.—Arc Lamp Suspension Pulley.

By slightly raising the lamp, the knob upon the rope engages the nearest bifurcated end of the swinging pawl, which revolves upon its axis into the position shown in Fig. 2, the other end of the pawl swinging under the knob upon the rope. The lower, or supporting, pawl is securely held in position by the upper pawl as shown in Fig. 2. The

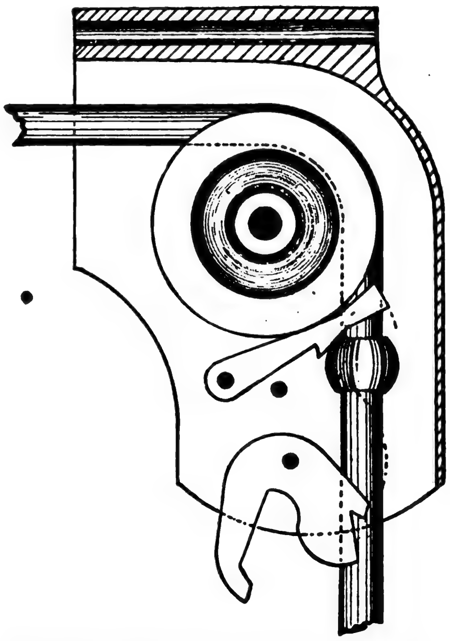

Fig. 3.—Arc Lamp Suspension Pulley.

lamp is thus supported by the knob on the rope resting upon the lower pawl.

To release the mechanism, the lamp is raised until the knob on the rope engages the end of the upper pawl, which is by this means raised enough to release the lower pawl; the latter then swings downward and permits the lamp to

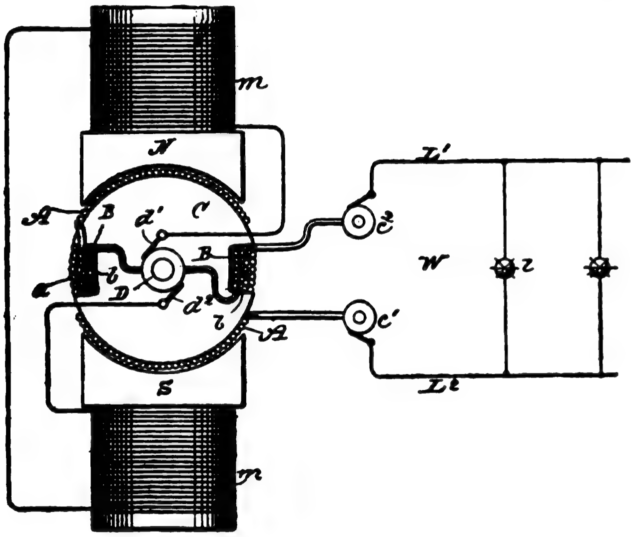
be lowered. The whole mechanism is controlled by the hoisting rope, and no auxillary cord is needed.

The mechanism is very simple and entirely automatic in its action. It is the invention of Jas. A. Lounsbury, of the National Engineering Bureau, of Chicago.

STANLEY'S SELF-REGULATING ALTERNATING MACHINE.

With the object of maintaining constant potential in alternating machines under all variations in load, Mr. Wm. Stanley, Jr., has recently designed a type of machine in which the excitation of the field magnet is automatically varied proportionately to the amount of load. He accomplishes this by the construction illustrated diagrammatically in the accompanying engraving, in which for the sake of clearness only two armature coils are shown, one supplying current to the external circuit and the other energizing the fields.

As will be seen, C is the armature-core, upon which are wound independent armature-coils, A B, at right angles to one another. The armature-coil, B, is wound in a recess, b, so that it lies within the exterior circumference of the core, and its terminals are connected with the field-magnet



Stanley's Self-Regulating Alternating Dynamo.

coils, m m, by means of a commutator, D, and brushes, d' d^2. The coil, A, is connected with the mains, L' L^2, by means of collector-rings, c' c^2. Applied to the coil, B, is a supplemental coil, a, consisting of a comparatively few turns of wire and connected in series with the coil, A.

It is evident that current from the coil, A, will flow through the supplemental coil, a, at the moment when the coil, B, is in its position of minimum electromotive force, and the flow of current through the coil, a, will develop lines of force in a direction operating to strengthen the polarity of the armature-core and increase the number of the lines of force threading the coil, B. On an increase in the current in the external circuit there will be a decrease in the difference of potential between the terminals of the coil, A, supplying current to the circuit, and in order to maintain the difference of potential constant an increase in the excitation of the field-magnets is necessary. The fall in potential is, however, accompanied by an increased flow of current in the external circuit, and consequently through the supplemental coil, a, and the number of lines of force of the magnetic field of the machine threading the coil, B, is augmented by the additional lines of force developed by the increased flow of current through the coil, a; hence there will be an increase in the potential developed in the coil, B, with a corresponding increase in the excitation of the field-magnets, and the difference of potential between the terminals of the work-circuit will be maintained constant.

Conversely, the tendency to a rise in the difference of potential between the terminals of the work-circuit consequent upon a decrease in load will be checked, since the number of lines of force threading the coil, B, will decrease with the decrease in the quantity of current flowing through the coil, a.

It is evident that the position of the coil, a, will be reversed with each reversal in the direction of the current flowing through it, and thus the lines of force developed by the current in the coil, a, will maintain a constant direction, as related to the direction of the lines of force of the magnetic field of the machine, and will always operate to assist the magnetization of the armature-core.

THE ELECTRICIAN OF THE CHICAGO WORLD'S FAIR.

We have received a copy of the following petition:—

We, the undersigned, representing electrical interests and industries, request the selection of Mr. J. P. Barrett, Electrician of the City of Chicago, by the Board of Directors of the World's Columbian Exposition, to have practical charge and control of the Electrical Department of the Columbian Exposition:

Frank A. Wunder, Western Agent Schuyler Electric Company; Frank J. Baker, Western Agent United Electric Traction Co.; F. S. Terry, Manager the Electrical Supply Co., President Chicago Arc Light and Power Co.; B. E. Sunny, Western Manager Thomson-Houston Electric Co.; F. S. Gorton, Manager the Chicago Edison Co.; W. P. Adams, General Manager Western Power Construction Co.; Herbert Wadsworth, Western Manager Excelsior Electric Co.; Jas. A. Lounsbury, National Engineering Bureau; H. F. Winston, President Illinois Electrical Material Co.; W. S. Salisbury, Electrician American Electric Motor Co.; E. M. Barton, President Western Electric Co.; C. A. Brown, Vice-President Electric Illuminating Co.; C. H. Wilson, Superintendent Chicago Telephone Co., President Chicago Telephone Co.; H. B. Stone, President Central Union Telegraph Co.; E. B. Chandler, General Western Agent Gamewell Fire Alarm Co.; L. B. Firman, General Manager the Police Telephone and Signal Co.; Francis W. Parker; George C. Bailey, Manager John A. Roebling's Sons Co.; F. G. Beach, President Chicago Electric Club; Foree Bain, Electrical Engineer, Chicago; John W. Calkins & Son, Chicago Office Rockford Electric Manufacturing Co.; E. E. Keller, Manager Chicago Office the North American Cons. Co.; E. L. Powers, Manager *Electrical Industries*; H. W. Hall, Manager the Hall Signal Co.; Edward Stockwell, Agent Ball Electric Light Co.; McIntosh Battery and Optical Co., 141 and 143 Wabash avenue; Electrical Merchandise Co., A. H. England, Secretary, 11 Adams street; J. L. Barclay, General District Agent Westinghouse Electric Co., Railway Department; B. F Stewart, President Emery Electric Mining Machine Co.; C. B. Osgood, Contracting Agent Westinghouse Electric Co., Railway Department; C. W. Barclay, 151 Van Buren street; Chas. T. Page, Secretary and Treasurer Englewood Electric Light Co.; Geo. H. Bliss; R. C. Clowry, Vice President and General Superintendent Western Union Telegraph Co.; F. H. Tubbs, Superintendent Western Union Telegraph Co.; W. J. Lloyd, Assistant Superintendent Western Union Telegraph Co.; Elbert C. Ferguson, Attorney, 94 La Salle street.

ELECTRIC WELDING AND ICE MACHINES.

The ice famine is proving a bonanza for the Thomson Electric Welding Co., says the *Boston Advertiser*. There is a great demand at present for pipe welding machines, with which to make the long coils of pipe for artificial ice machines, for brewery coils, for sugar refinery and general refrigerating purposes. The pipes originally come in lengths of from 18 to 20 feet. The coils are frequently 600 to 700 feet long. By old systems the pipe is welded together by a slow and laborious process, requiring fifteen minutes for each weld, two blacksmiths and a dozen helpers and a large space, each pipe being lifted from the forge to the anvil and a mandril inserted. There is often a serious loss of ammonia as a consequence of imperfect welding. By the electric process the welds can be made so homogeneous that there is no chance for ammonia to escape. The length of time required is two minutes for each weld, and all the help required is a man and a boy. The cost of the old process is fifteen cents each; by the new, two cents. As the coil is bent after each weld, the work can be done in a very small space. The managers of the Welding Company consider this, next to shell welding, the most important industry which has sprung up as a result of the welding invention.

A Magnet for Gold.—Mr. A. W. Chellis, has, it is stated, been exhibiting at Truckee, Cal., an "electric mineral ball," which has an attraction for gold.

THE STORAGE BATTERY IN TRACTION WORK [1]

BY J. K. PUMPELLY.

When I had the honor of addressing you a short time ago, I attempted to show how useful storage batteries could be made, and to what extent economy could be effected by them. The question was then asked, why it was that storage batteries had thus far failed to realize the predictions made concerning them. This question I propose to answer, basing my remarks upon actual tests that have been made in street car traction, the most difficult, probably, of all work they have been set to accomplish.

Why, with all this force at hand, and under control of man, has there been such failure in street car work? Let us study well the problem, and by the experience of practical, earnest men, determine whether we ought not to charge ourselves with much of the failure; we may find that the obstacles to success come from the outside, and not from the batteries themselves. We have given our young horse too much to do. Could we have understood the language of our straining, overworked street-car horse or the more patient mule, we would have known long ere this how varying is the traction work on a street car. To show this I need only cite Mr. A. Reckenzaun's very elaborate paper on electric traction.[2]

You will see by the practical notes of Mr. Reckenzaun, that the condition of the track and roadbed and the quickness, watchfulness and coolness of the switchman on the car platform, has much to do with the success of electrical traction, especially when a stored power is used. This last quality in the driver, or man who controls the out-put of current, who knows by experience what he needs and what is wasteful, can make the use of storage batteries economical, or otherwise. A car has lately been filled up with batteries at the order of the Middleborough Land Co., of Kentucky, which is completely controlled by the switchman. The batteries are connected in parallels of 25 cells each, aside from the regular series connections, and as 100 cells compose the outfit, the switch is divided into sections of four with resistance between each section to prevent flashing, when rapid changes are made under a strong current. Thus the switch acts much as does the steam throttle in the hands of the engineer.

To give the first impulses for a start, 25 cells of the battery are thrown into circuit with the motor, which is thus saved from heating or straining, and at the same time feeds the impulse of magnetization which starts the armature; the counter E. M. F. which begins to be created as the armature revolves, permits of a stronger current and the movement of the switch to the next segment, throwing in 50 cells and then 75. When the car is well in motion the counter E. M. F. allows of the entire battery of 100 cells being switched in series. Thus it can be seen that although a current of 50, 60 or 80 amperes is needed to start a loaded car, this current is divided up so that one group of batteries helps the other by dividing up the load, taking less out of each cell and also saving the motor from heating.

Still the question is asked, Why, if the success is such as represented on the above mentioned road, are not all doubts settled and the storage battery generally adopted? It is certainly the ideal method for street-car traction; each car being independent of any other, motion can be forward or backward. A car can even be run off the track, and if out of order run over the main road to the car house, if not too far away. There are two reasons for this hesitation. First, some of the batteries heretofore used are not durable enough, their mechanical building up or putting together of the plates fails to resist the jar of the railway and the sudden increased draught of current to which the battery is often subjected. In these batteries any touching of the two opposite pole plates destroys the efficiency of the entire set and nothing can be done to remedy the evil for the time, but to take out the one disabled cell and put in another. Now this tendency of the plates to get together is constant and comes very likely from the unequal expansion of the lead support which holds the active material and is a conductor for the current. There is also a tendency of the blocks of active material to flake off or to fall out under a jar, the pieces or flakes often catching between the two plates, which are never over ¼ of an inch apart, and thus short-circuiting the battery and rendering it useless. Fine crystals of lead sulphate slowly form between the plates, and in this way do the damage in the most mysterious manner, for these crystals can hardly be seen.

The second reason is to be found in the weight of the battery, and as constant efficiency depends very much on the weight of lead and lead oxide of which the battery is made to-day, it cannot be avoided unless the managers of the road look at it in the right way and arrange shorter trips and more frequent changes. For instance, suppose a six hours trip of 40 or 50 miles (like the example mentioned above), needs a battery of 150 ampere-hours capacity; to obtain this capacity we must have at least 80 batteries weighing 35, or, more likely, 40 pounds each; all this weight besides the car, motor and load must be supported and propelled by the forces excited in the battery itself. What would be the most practical and sensible way to improve this condition? Surely to shorten the trips, and as we learn by experiment that it needs a battery of 150 ampere hours capacity (and which capacity depends upon a certain weight of batteries), to run 50 miles at 8 miles an hour, then why not use a 100 ampere-hour battery, weighing say 25 lbs., and run 30 mile trips. The batteries, being lighter, could more quickly and easily be slid into and out of the car, more quickly charged, and cost less money per cell. If the trip occupied four hours to run the 30 miles, then four hours would be sufficient to charge the exhausted battery with 100 amperes, the dynamo delivering a current, in charging, of 35 amperes per hour, which would be a fair normal current for a properly constructed battery.

Most of the batteries of this size and weight will not bear a charging current of 35 amperes, and this has been one of the troubles that the experimental street railways have had to contend with. I am sure, however, that a battery is now on the market which will take such a current, will not get out of order, will not be injured by jar or heavy current discharge, in which the plates lie horizontal in the cell, and all opposing pole plates are separated from each other by intervening sheets of porous absorbing and non-conducting cellular fibre, inert and non-corroding in the electrolyte, and by reason of which the internal resistance is not increased, although it has been contended by many that this latter objection would exist.

I am also quite confident that another battery will soon appear in which faults before found in storage batteries will be overcome, not by lessening the weight of the battery, but by avoiding uncertainties caused by buckling, etc. These batteries are mentioned here merely to show that when all the arrangements are made on the road, their ability through proper construction to do the work constantly, can be depended upon. If, indeed, we have not this certainty of durability, all data, all estimates are useless and merely waste of time and money.

A word regarding the economy of traction by storage battery compared with that by means of the overhead wire. It takes an engine of at least 250 h. p. and a dynamo of the same power, constantly running, to propel seven cars over the above-mentioned route. To charge 560 batteries, that is, one set of 80 cells for each of the seven cars, would need an engine of 58 h. p., a dynamo of the same power of 1,340 volts, delivering a current of 35 amperes; and this dynamo would have to run four hours. If the trips were arranged for a change of batteries every four hours after the first set were charged, a 58 horse-power dynamo and engine would do the work, or, better, two 30 horse-power dynamos running only part of the time.

The dynamo for the overhead system must keep the E. M. F. constant, whether seven cars are running, or a less number. It must also supply such constant E. M. F. that the motor at the end of the wire, six miles away, shall receive the same electrical impulse as at the end near the source of power, and it is well-known what the drop in the line is per mile and the loss of power. We find that 10 per cent. yearly on the first cost of the batteries will make up for any deterioration in a well-made battery, and that amount will keep in order the overhead wires.

It might be of interest to mention here in closing the Patton motor system now being thoroughly tried at Pullman, in which great interest is taken by street railroad men, not only because it can be made quite independent of short stations, avoids the necessity of charging batteries and can use as trailers hundreds of street cars too lightly made or too old to support a set of heavy batteries.

The locomotive car is something like the grip car, although it carries in the centre a gas engine of 7½ h. p., with a tank sufficient to supply fuel for many hours and a dynamo of 7½ h. p.; while underneath are 60 storage cells and a motor of 15 h. p. In front there is still room to seat 20 or 30 persons.

By referring to the data on traction, just read, you will appreciate the principle and economy of this plan. We learn that an average run on the generally used lines of street railway uses 4½ h. p. of energy and only in starting, ascending grades or turning short corners is much more power needed. Hence in the Patton system a current sufficient to charge 60 cells with 15 amperes, under a pressure of 170 volts would keep the batteries charged, although part of the current, sufficient to generate 4½ h. p., was being constantly drawn out of the battery while running on a level.

Now, as the pressure is constant at about 2.4 volts for each cell, or about 170 volts, the current necessary to do the work is drawn from the battery; when the pull comes, such as ascending grades, going around curves, or starting, then the counter E. M. F. developed in the motor, which is wound to develop 20 h. p. under the pull, would lower the voltage to that of the sixty cells on discharge. The instant this takes place, the current flowing into the motor from the batteries is always sufficient to develop the full power needed, and this equilibrium is automatic. As the voltage of a battery on the first moment of discharge is always higher by .1 of a volt per cell there would be developed from the battery of 60 cells, at the moment it was called upon, a higher efficiency than could be estimated on a basis of average efficiency, and hence we

1. Abstract of paper read at the Second Annual Meeting of the Chicago Electric Club.

2. See The Electrical Engineer, June 18, 1890.

learn from varied trials that the battery thus constantly charged exerts tremendous and unestimated energy at the moment, very much as a man or a horse can exert unusual power under excitement or strain.

It is found that on a level track, two loaded cars can be drawn at the rate of 12 miles an hour, around curves and up 3% and 4% grades, and often when the longest runs have been made on a level, needing only 4½ h. p. and the cells have become so fully charged that the engine is shut off and many miles are run with the battery alone. In this case also the E. M. F. from the battery can always start the gas engine. Now if a 7½ h. p. engine and dynamo will do the work by the use of the most condensed and convenient form of fuel, seven cars would need only 52½ h. p. in engines.

It is claimed that this car, with one loaded car attached, can be run at a cost of 1¼ cents per hour. The size of the oil tank, which it would be convenient to carry, would be the only limit to the distance run. Of course, stations at proper distances apart could be made, to renew the tanks. In a short time every day work, the only real test to success, will show just how practical and economical this, like other systems, can be.

CORRESPONDENCE.

CHICAGO.

A New Conduit Railway System—A New Washburn & Moen Plant—Street Lighting—Electric Railway Work.

MR. C. K. HARDING, an inventor of Des Moines, Ia., is stated as having perfected an entirely new underground electric system for operating street cars without the use of the unsightly overhead wires. He abandons the slot idea, which has been heretofore unsuccessfully worked upon by numberless inventors, and used a tight conduit in which the main wire may be thoroughly insulated. A company has been formed with a capital stock of $600,000 to push the invention.

A rumor was recently circulated to the effect that the Washburn & Moen Manufacturing Company of Worcester, Mass., who produce an enormous amount of iron and copper wire every year at their large factories, a large portion of which output is used in electrical work, were negotiating for the purchase of a large tract of land in South Chicago for the erection of extensive works. It is now definitely understood that an arrangement has practically been completed for the purchase of fifty acres of land lying directly south of the property occupied by the Calumet Iron and Steel Company. The only step necessary to a consummation of the deal is the examination of the titles and the signing of the necessary papers.

An application for the extension of the electric lights on West Lake Street, as far as Western Avenue and around Union Park, on Randolph Street, has been favorably considered by Controller Onahan. There is plenty of room for increasing the number of arc lights now in use for street lighting, and we hope the day is not far distant when the brilliant and penetrating arc-lamp will supercede the sickly gas-lamps which now vainly struggle to illuminate Chicago's magnificent boulevards. It is time the pallid gas jets were laid away in innocuous desuetude to make place for their incomparable successor, electricity.

The Calumet Electric Railway Company has been stopped by the Street Department from proceeding with the laying of tracks on Ninetieth Street and Mackinaw Avenue, South Chicago, because the rails have not been submitted to the Commissioner of Public Works for his approval, as required by the ordinance. The representatives of the Company called upon Commissioner Purdy Wesday afternoon and informed him they could furnish a certain kind of rail, which the Commissioner said was satisfactory, and he therefore permitted them to go on with the work.

CHICAGO, July 4, 1890.

BOSTON.

Villard Deal—Heavy Traffic in Electric Roads—Governor Brackett Vetoes the Consolidation Bill.

MESSRS. COFFIN AND GRIFFIN of the Thomson-Houston Electric Company have returned from New York, and report has it that the Villard deal has not gone through. Mr. Villard has sailed for Europe and it is not expected that any further transactions will be entered upon until his return. The pooled stock can either remain, pending further negotiations, or be taken out at the option of the stockholders.

The electrical system of the West End Company has been taxed to the utmost this week, when it became necessary to transport about 10,000 people every evening to and from Oakland Garden, where the gigantic spectacular play of the Fall of Babylon is being enacted. With the exception of a few delays on the opening night, it is creditable to the management of the road that they have managed successfully to cope with the enormously increased traffic.

Governor Brackett has vetoed the bill authorizing the consolidation of gas and electric companies. His chief objections were the chance for unlimited expansion and the valuation of the new stock for taxation.

The legislative investigation as to the methods of the West End Company in procuring the passage of their bill is finished, and a unanimous report has been presented by the special committee and accepted, in which it finds that the charges of bribery are wholly unsustained, but admits that large lobbying expenses were incurred, not only in entertaining members, but in retaining such members as were deemed necessary.

As a consequence of the above report, the House of Representatives has passed the West End Bill for an elevated road to be engrossed on a vote of 97 to 72, and has also passed a bill to legalize the lobby, as suggested also by the special committee's report. The next step was to obtain Governor Brackett's signature to the West End Bill, and this was obtained at 11 o'clock on Tuesday night, and the West End Elevated bill has now become a law. Half an hour later Secretary of State Pierce announced the prorogation of the Legislature for the season.

BOSTON, July 5, 1890.

A NEW YORK GENERAL SUBWAY COMMISSION PROPOSED.

The last act of the June Grand Jury was to make the following presentment in Part I. General Sessions:—

From evidence presented to the Grand Jury we find that the contiguity of steam, gas, and water pipes, of sewers and electric subways in and under the roadbed of our principal streets, is an evil which demands immediate relief. The uptearing of the pavements caused by the laying of these pipes and their frequent repairs is an obstruction to travel and a needless expense to the city. The over-heating of the soil and the adjacent water pipes is destructive to pavements of asphalt, and makes Croton water unfit to drink. The saturation of the soil with poisonous gases and dirty fluids is damaging to health. The explosion of gases and the liability to explosion by steam are constant menances to life and limb.

These evils have increased from year to year, and will continue to increase unless some remedy is found.

As a present remedy we suggest that steam and gas companies be held to strict accountability for all damages occasioned by their neglect, that penalties be rigidly enforced against companies that delay repairs and obstruct travel, that no more permits be granted for the laying of additional steam and gas pipes in streets that are now overcrowded.

As a future remedy, we suggest the appointment by the proper authorities of a commission of strictly non-political experts who shall consider the feasibility of vesting the management of street paving and of all underground pipes and sewers, and of devising a new system by which the benefits of steam, gas, water, electricity, and sewage can be had more safely, and with less official obstructions.

REMARKABLE EFFECT OF ELECTRIC OSCILLATIONS.

A remarkable effect of electric oscillations has been recently pointed out by Prof. Minchin in *Nature*. Two metal plates attached to platinum wires are sealed in a closed glass vessel containing alcohol. One of these plates has been previously sensitised by some process not described; and it is found that, if light falls upon this its potential differs from that of the second plate by more than half a volt, and may be detected by an electrometer. A slight tap will, however, render the cell insensitive to light; a second tap will restore the sensitive condition, and so on, the two states occurring alternately, and being indicated by the movements of the needle to and from the zero position. The influence of an electric spark on such a cell is still more remarkable. If the cell is in the insensitive condition, the sensitive state can be at once restored by simply causing a spark to pass between the terminals of a Wimshurst machine or of a Hertz oscillator. The effect takes place even if the spark is caused at a distance of many feet from the cell. Prof. Minchin explains the effects by assuming that the molecular state of the surface is altered, and assumes that light energy can be taken up electrically for one condition but not for the other.

COMPLAINING LONDON TELEGRAPHERS.

The agitation among the telegraph operators for higher wages is assuming serious proportions, and is causing great delay in the service. It has even been rumored that the British Government will apply to the American telegraph companies for a large force of operators in case the dissatisfied men go on strike. The employés are indignant over this proposed action and will request their American craftsmen not to help the Government to grind them down to starvation wages. Several employés were discharged last week for participating in the indignation meetings. A wholesale strike is expected this week.

SOCIETY AND CLUB NOTES.

NATIONAL TELEPHONE EXCHANGE ASSOCIATION.

Gen. C. H. Barney, secretary, has issued the following notice:—

The next annual meeting of this Association will be held at the Russell House, Detroit, Michigan, commencing on Tuesday, September 9th, next. It is expected that the business of the Association will be concluded in two days, but the Secretary has received a hint that it will be advisable for the delegates to make their plans so as to remain in Detroit until Thursday evening at least.

The Russell House is conducted on the American plan. The rates are $3, $3.50, $4 and $4.50 per day, according to location, and accommodations desired. It is requested that members of the Association intending to be present at the meeting, engage their rooms at an early date, so that the most desirable locations may be secured. Messrs. W. A. Jackson and F. A. Forbes, of the Telephone and Telegraph Construction Company, of Detroit, have kindly consented to act as a committee on quarters, and a note addressed to either of them will receive prompt attention.

It is not too soon to commence the preparation of papers to be read at the meeting. Members of the Association are earnestly requested to send such papers to the Secretary by the first of August, if possible, so that the Executive Committee may have sufficient time to examine them.

COLLEGE NOTES.

MASS. INSTITUTE OF TECHNOLOGY.

The class recently graduated was the largest ever sent out from the institute, 108. The members are divided among the courses as follows:—Civil Engineering, 25; Mechanical Engineering, 27; Mining Engineering, 4; Architecture, 5; Chemistry, 13; Electrical Engineering, 18; Natural History, 3; Physics, 2; General Studies, 6.

Three of the recent graduates in the Electrical Department, together with one Physicist, return to the institute as assistants next year: Messrs. H. M. Goodwin, F. W. Swantor and W. L. Smith, in the Department of Physics, and Mr. H. E. Hayer to the Mechanical Department.

Mr. Harry W. Tyler, Instructor in Mathematics, who has been acting as Secretary to the Faculty the past year, has been appointed Assistant Professor of Mathematics.

HARVARD UNIVERSITY.

The *Announcement of Courses* for 1890–91 has made its appearance rather late on account of numerous changes in the different courses. In addition, the various departments have issued separate pamphlets containing a more detailed account of the instruction offered. Taken as a whole, the chief feature in the announcement is the division of the courses of each department into three groups: Those primarily for *Undergraduates*; those for *Undergraduates and Graduates*; and those primarily for *Graduates*. The courses primarily for undergraduates are open to graduates, but do not usually count toward any of the higher degrees. To the courses primarily for graduates, undergraduates are admitted only on recommendation of the instructor.

In the mathematical department the courses may be roughly divided into elementary and higher courses. The elementary courses include Trigonometry, Analytic Geometry, Elementary, or Extended Algebra, Solid Geometry, and Special Trigonometry. The higher courses may be divided into five groups; Calculus, Modern Analysis, Quaternions, Mechanics, Applications. The *Calculus* group contains besides two courses specially upon the subject, Spherical Harmonics, Theory of Functions, and a Research course. *Modern Analysis* comprises Analytic Geometry (Modern Development), Determinants, Invariants, Theory of Substitutions, Higher Theory of Equations, and Theories of Functions of Multiple Algebras, and of Qualitive and Logical Algebras. *Quaternions* includes two courses in which the subject is combined with Mechanics. *Mechanics* includes, besides an elementary course, instruction in Analytic Mechanics, Hydromechanics, Wave Motion, and various questions of importance to physicists and mathematicians. *Applications* deals with Navigation and with Astronomy.

In the Physics department the various courses are introduced by courses B and C, which give practice in accurate scientific methods. Course 1 is intended for those who wish to acquire a general knowledge of Physics. Courses 3, 4, and 8 treat respectively of Electrostatics, Electrodynamics, and the Theory and Management of Dynamos. Course 5 is a treatment of Optical Phenomena. Courses 6 and 7 are upon Thermodynamics, and upon the Theory and Management of Heat Engines. In the graduate group are courses 9 and 10 upon the Mathematical Theory of Electrostatics and of Electrodynamics. In addition there are courses of Research Upon Spectrum Analysis, Problems in Mathematical Physics, and Electromagnetism and Heat Conduction. Nearly all of these courses consist of lectures and laboratory work in the fine Jefferson Laboratory, where there is opportunity for one to become a second Sir William Thomson.

In the changes of the corps of instructors, Prof. J. M. Pierce returns to the Mathematical department from his sabbatical vacation; Messrs. Anderegg and Bailey retire from the same department; Dr. Whiting and Mr. Buckingham retire from the Physics department and Messrs. Sabine and Hooper take their places. The Electric Club has adjourned until the end of vacation.

REPORTS OF COMPANIES.

DIVIDENDS.

THE CONGAREE GAS AND ELECTRIC CO., of Charleston, S. C., has declared a semi-annual dividend of 3 per cent.

STOCKS AND BONDS.

SAN ANTONIO, TEX.—C. Guergin, Mayor of San Antonio, will receive proposals until July 19 for the purchase of 5 per cent 20-30 year $1000 bonds, including $25,000 for an electric fire alarm system.

OBITUARY—D. NAPOLI.

It is with extreme regret that we announce the death, on the 29th of May, of M. Daniel Napoli, head of the laboratory of the Eastern Railway Company of France. Born at Naples, on the 27th of April, 1840, M. Napoli came to Paris at an early age, and entered the employment of the Eastern Railway Company as an apprenticed fitter, where his intelligence and great manual skill soon attracted attention. In the field of electricity M. Napoli was the inventor of several skilful contrivances, such as electric clocks and electric alarms. To him also were due some ingenious devices connected with the Reynier-Werdermann lamp. He took an active part in organizing the first Electrical Exhibition of 1881; and his work in connection with the Association Polytechnique gave valuable aid to the popularization of science. M. Napoli was no mean sculptor, and several of his works found a place in the *Salon;* amongst which were busts of Ampère, Gramme, and Alexander Graham Bell. He was Chevalier of the Legion of Honor, officer of the Academy, President of the Société de Navigation Aérienne, and "Secrétaire-fondateur" of the Société Internationale des Electriciens.

INVENTORS' RECORD.

Patents issued July 1, 1890.

Alarms and Signals:—*Electrical Call-Box*, G. F. Gale, 431,141. *Electric Bell*, P. B. Delany, 431,181. *High and Low Water Alarm for Steam-Boilers*, J. McFarlane, 431,271.

Conductors, Conduits and Insulators:—*Protective Covering for Electric Cables*, J. H. Cheever, 431,104.

Distribution:—*System of Electrical Distribution*, L. Gutman, 431,460.

Dynamos and Motors:—*Dynamo-Electric Machine*, C. P. Winkler, 431,184. *Electro-Magnetic Drill System*, H. N. Marvin, 431,170. *Regulation of Dynamo-Electric Machines*, W. Stanley, Jr., 431,216. *Self-Regulating Dynamo-Electric Generator*, W. Stanley, Jr., 431,217. *Self-Exciting Alternating-Current Electric Generator*, W. Stanley, Jr., 431,218. *Dynamo-Electric Machine*, O. B. Shallenberger, 431,235. *Mining Machine*, J. M. Walter, 431,239. *Reciprocating Electric Engine*, C. J. Van Depoele, 431,492, 431,493 and 431,495. *Reciprocating Electric Engine System*, C. J. Van Depoele, 431,494 and 431,496.

Galvanic Batteries:—*Electric Battery*, M. W. Parrish, 431,073.

Lamps and Appurtenances:—*Ceiling-Block Connector for Incandescent Lamps*, L. W. Dillon, 431,038. *Electric Lamp Fixture*, S. Bergmann, 431,320.

Measurement:—*Electric Meter*, J. Couderay, 431,248.

Metal Working:—*Electric Soldering Iron*, C. L. Coffin, 431,439.

Miscellaneous:—*Electric Cut-Out*, L. Daft, 431,035. *Fuse-Block*, J. L. Kimball and H. C. Wirt, 431,062. *Electric Switch*, O. P. Loomis, 431,118. *Multiple Fusible Cut-Out*, L. B. Favor, 431,185. *Multiple Thermal Cut-Out*, L. B. Favor, 431,186. *Electric Connector*, H. Studte, 431,412. *Automatic Cut-Out*, A. L. Haines, 431,516.

Railways and Appliances:—*System of Electric Locomotion*, F. Wheeler, 431,092, 431,093 and 431,095. *Switches for Electric-Railway Systems*, F. Wheeler, 431,094. *Electric Motor for Railway-Cars*, W. McDougall, 431,213. *Suspended Electric Railway and Car*, F. E. Drawn, 431,256. *Electric Railway-Signal Apparatus*, W. Smee, 431,408. *Electric Railway Conductor*, E. Thomson, 431,414. *System of Distribution for Electric Railways*, E. E. Ries, 431,482. *Electric Railway*, R. M. Hunter, 431,519.

Secondary Batteries:—*Secondary Battery*, T. M. Foote, 431,341. *Secondary Battery*, T. S. E. Dixon, 431,417.

Telephones and Apparatus:—*Individual-Call Devices for Telephones*, C. H. Vincent, 431,068. *Telephone Signal Apparatus*, J. A. Seely, 431,531.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

ELECTRIC MOTORS IN NEW ENGLAND MILLS.

For a year or more electrical engineers have been trying, says the Boston *Commercial Bulletin*, to induce New England manufacturers to introduce electricity into their factories as a motive-power to run their machinery, by subdividing the power up into units. It was set forth that such a method would result in a considerable saving to the concern, as less friction would have to be overcome, therefore less power would be required. Generally, the power is centralized, even in cases where electricity is used, one motor doing all the work. By dividing the power, the expense will average less, as current can be used as needed. One or more of the motors can be shut down at will, whereas, when the electric power is centralized, the one motor used must be run for any amount of work to be done. The great hindrance to the division of power is the original cost. Small motors with the same total horse-power as one large motor will cost the most, but it is claimed the saving in running will pay for the difference in a short time. At present, many manufacturers are watching the working of the plant in the M. A. Packard & Co. Shoe Factory, at Brockton, Mass. The electric-power there is divided into 3 units, a 15 h. p. motor furnishing power for the bottoming department, a 10 h. p. motor for the sole leather department and elevator, and a 5 h. p. motor for the stitching department. Formerly, for a year and a half, 1 motor of 25 h. p. capacity run the machinery of the whole concern. By the change, it is claimed, the saving will be 6 h. p. The local electric light and power company, in view of this, have agreed to furnish power for less than when one motor was used. In this plant Sprague apparatus is used throughout.

FORT WAYNE PLANTS.

Mr. H. C. Adams, New York agent of the Fort Wayne Electric Co. advises us that their representative, Mr. A. G. Greenberg, has just closed a contract with the Ilion and Mohawk Gas Light Co., Ilion, N. Y., for a plant of 60 lights of 2000 c. p. each of the new Wood arc system.

NICKEL-IN-THE-SLOT TELEPHONY.

A novel telephone station is being introduced in Connecticut. The instrument cannot be used unless a fee is paid. There are five slots in the machine for the reception of a nickel, ten-cent piece, quarter, half-dollar and dollar, respectively. These amounts cover the rates charged for telephoning to various places in and out of the State. To use the telephone it is first necessary to call up the central, as on an ordinary telephone. The objective point is then asked for, and when this is reached the party who rings up is told to put the necessary fee in the slot. If five cents is dropped in the slot it strikes a bell of a high note, once. Ten cents strikes a bell of the same note, twice. A quarter strikes a bell of a lower note, once. A half dollar strikes that bell twice, while a silver dollar strikes a very low tone "Cathedral Gong."

The Southern New England Telephone Company, has arranged to place a large number of these instruments in Connecticut, as rapidly as they can be furnished.

REYNIER ACCUMULATORS.

M. Reynier has recently exhibited some new accumulators invented by him, which he calls elastic accumulators. The plates, prepared in special manner, are corrugated and placed one against the other, separated by a padding of silica. The elements are placed in elastic receptacles, which are all compressed together. Further details are promised of this accumulator, the gross weight of which is stated as very small for the output.

NEW WESTINGHOUSE ARC AND INCANDESCENT PLANTS.

The Brush Electric Light Company, of Baltimore, Md., having again been awarded the contract for lighting the city, is now obliged to increase the capacity of its central station apparatus. A contract for alternating current machinery for 3000 lights was made with the Westinghouse Electric Company a few days ago. This makes the Baltimore plant one of the largest alternating current central stations in the country.

One of the latest towns in New York state in which the Westinghouse alternating apparatus has been introduced is Tonawanda. The plant has a capacity of 500 incandescent lamps.

The Westinghouse Electric Company is installing alternate current apparatus for a central station plant of electric lighting in Carrolton, Mo. The plant will have a capacity of 500 lights.

The beautiful little town with the romantic name of Crystal Falls, Mich., is about ready for a large sized boom. The first visible sign of its march to progress is the establishment of a central station plant for electric lighting, for which the Westinghouse Electric Company has received the contract to furnish alternating current apparatus of a capacity of 750 lights.

The Westinghouse Illuminating Co., of Schenectady, N. Y., has been making considerable improvement in its central station plant of alternate current electric lighting. A new alternate current arc light machine has lately been added to the plant.

The Westinghouse Electric Company reports the following orders received during the month of June for alternate current central station apparatus: Moundsville, Va., 500; Valdosta, Ga., 500; Newark, N. J., increase, 1500; Cleburne, Tex., 500; Newport, R. I., increase, 500; Hamilton, O., 500; Tacoma, Wash., increase, 1500; Vinton, Iowa, 500; Hiawatha, Kan., 500; Saginaw, Mich., 750; Tonawanda, N. Y., 500; Philadelphia, Pa., 750; Crystal Falls, Mich., 750; Oconto, Wis., 750, increase; Ogden, Utah, 1500; Baltimore, Md., increase, 3000.

Arc lighting apparatus, of the new Westinghouse arc light system, was sold for central station purposes in the following towns: Valdosta, Ga., 40; Ogden, Utah, 80; Schenectady, N. Y., 50; Rockville, Ind. During the month a large arc light plant was also ordered for the Zoological Gardens at Cincinnati.

TESTIMONIALS ON THE INTERIOR CONDUIT SYSTEM.

The Interior Conduit and Insulation Company, 16 and 18 Broad street, have just issued a pamphlet containing a number of testimonials on the merits of their system of wiring. One is from Mr. Edison and another is from Prof. Elihu Thomson. A third is from Mr. F. Kitton, of Buffalo, inspector for the Association of Fire Underwriters there. Mr. Foree Bain also endorses it heartily as a whole and in detail. Mr. W. E. Burnham, of the firm of Eaton, Cole & Burnham Co., whose house has been fitted up with the system, speaks most highly of it. An extract commending the system is also given from a paper read by Prof. Thomson before the National Electric Light Association, and this is followed by extracts from the rules of the various boards of fire underwriters, indicative of the forcible way in which they approve of the system as an ideal and practical means of wiring a building scientifically and safely.

THE WILMOT & HOBBS MANUFACTURING CO.

The above enterprising concern of Bridgeport, Conn., have just issued a new price list of their gong bells. They make bell steel gongs 1¾ to 5 inches in diameter, of a special grade of metal used only by themselves, giving the bells a beautiful clearness of tone. Their bells are also furnished nickel or brass-plated. They have their own rolling mills, tool making, manufacturing, brass and nickel-plating departments, and are thoroughly equipped for putting out the best goods. They do not mount their gongs in any way for the trade, but furnish their gongs simply in the sizes desired, and with a 3-16th inch hole unless otherwise ordered. A large stock is always carried. The company invite correspondence in regard to their specialties.

BUZZING IN TELEPHONES,

According to Mr. R. Appleyard, if a microphone be delicately adjusted and mounted on a resonating box, it will be set into continuous vibration when a sufficiently strong current is sent through it.

In the experiment, the fixed carbon pieces were small blocks with rounded contact surfaces. The vibrators were of square or oblong section, in some cases grooved below, so as to form two points of contact where resting on the fixed blocks.

The time of vibration varied, of course, with the particular vibrator employed; but, by suitably choosing these, almost any rate could be attained, from a steady sway from side to side with the heavier ones, to a decided "buzz" when a slender rod was used.

There is no doubt that the motion is a Trevelyan-rocker effect. The "buzzing" is similar to that heard in a telephone when in circuit with a faulty transmitter, and this latter nuisance is probably, in part at least, produced in the same way.

DOUBLE CARBON ARC LAMPS.

A special dispatch from Pittsburgh of July 5, says:—The Brush Electric Light Company brought suit in the United States Circuit Court to-day against the Westinghouse Electric Company asking that they be enjoined from making, using or selling any electric arc lamps embodying the claims of the plaintiffs. The case is for the alleged infringement of electric lamps, using the double carbon system, designated in this case as "Indianapolis Jenney double carbon lamp," and in which two pairs of carbons are independently adjusted and controlled and burned successfully, one pair of carbons being consumed, or practically consumed, prior to the establishment of the arc and the burning of the other pair.

WESTERN TRADE NOTES.

KNAPP ELECTRICAL WORKS, 54 Franklin street, Chicago, report business as exceedingly good. During the recent hot spell the call for their motor fan outfits has been very large. There is no let-up on the quantity of Grimshaw white core and other specialties sold, and Knapp annunciators are also in large demand.

BAIN LIGHTNING ARRESTER.—A highly novel and ingenious lighting arrester has just been invented by Mr. Foree Bain, of Chicago. The principles employed in its operation are entirely new, and appear to be full of merit. It was seen in practical operation, a 100 light incandescent machine being used for the purpose, and the results were highly satisfactory.

MR. J. E. WILSON, of the Western Power Construction Company, Rookery, Chicago, who handle the famous McIntosh Seymour engines in the West, has just returned from a flying trip to Boston, whither he went on important business. He made but a very brief stay at the Hub, as he had many important matters to look after here, the company's business being unprecedented in its volume and extent, although it has been in the field but a short time.

THE L. J. WING COMPANY, of 96 Lake street, Chicago, are having quite a run on their Disc fan. These fans may be operated by any power, but an electric motor is preferable, being so adequately fitted to fill all requirements. They manufacture a very handsome disc fan and electric motor combination. The motors are built as a part of the fan and require a minimum power for driving. They do not obstruct the light and run practically noiselessly.

W. CALKINS & SON, 175 Munroe street, have opened a Chicago office of the well and favorably known Rockford Electric Manufacturing Company, of Rockford, Ill., manufacturers of the Mayo electric light and power apparatus. This company furnished all the motors for running the printing presses and other work in the *Inter-Ocean* building, and this plant is giving the best of satisfaction. Mr. Calkins has been prominently connected with the company from its start, and in the management of the Chicago office many advantages will accrue to all concerned. The company manufactures a complete system of arc and incandescent lighting and electric power apparatus.

THE ELECTRIC MERCHANDISE CO., 11 E. Adams street, are finding a large and ready market for their electric railway specialties. They are, if we are not mistaken, the only supply company of the kind in the country that confines itself exclusively to the manufacture and vending of supplies solely for electric street railways. Mr. Mason and his staff are thoroughly cognizant of the requirements in this line, and it is safe to say that to no better development in electricity could they have turned their attention, as the field is almost infinite, and success is greatly dependent on the minute details of construction and apparatus. They are completely independent and tied down to no particular system, so that all the improvements which they have and will introduce are open for adoption by all roads operating with electric power.

ROCKFORD ELECTRIC MANUFACTURING CO.—The development of the business of this company has been so rapid, that no sooner had they arrived at their maximum efficiency in the organization of their working force in their present large quarters than they found it absolutely necessary to expand and expand at once. With this end in view arrangements are now about consummated whereby they will shortly occupy two large factory buildings near their present site, where they will have room for 500 hands, or more. Another section of the town was at one time talked of as a location for their new works, and the "boomers" in the vicinity offered the company a large amount in spot cash to locate near them; however, as this would have necessitated the use of steam, they have decided on occupying a position near their present works where water power is excellent. The new factory will be equipped with the latest and most improved machinery and tools, under the direction of General Manager Eaton, and under the personal supervision of Mr. George Mayo.

J. LANG & CO., 44 Michigan street, Chicago, are remarkably busy turning out their well-known switches, gas attachments and other specialties, now so largely used by electrical companies; both their steam and electric departments are taxed to their full capacity. They are at present manufacturing, amongst other work, four switches of 1,000 amperes each for the Chicago Edison Company's central station on Adams street, where they already have in constant operation more than one hundred of these switches, ranging in capacity from 600 to 1,000 amperes; also two switches of special design for the Belding Motor Company to control two large electric motors for A. Booth & Sons, the fish packers of this city; twenty Andrews switches of 250 amperes each; three 3-pole switches, and six Andrews switches, which will be used by the Chicago Edison Co. in the Wisconsin Central depot, of a capacity of 400 amperes each. They have put out some 60,000 of their combination gas attachments in the past two years. They have a fine assortment of orders on hand for their automatic water gauges and Chicago free-seated gauge cocks, and are altogether well satisfied with the business on hand and the wonderfully bright prospects for the future.

NEW ENGLAND TRADE NOTES.

MR. DAVID DUNN, accompanied by a number of Pittsburgh gentlemen favored Boston with a short visit this week, and doubtless felt on his departure that he had been mercifully allowed to sojourn if only for a few days once more "in God's country."

THE STANDAND ELECTRIC COMPANY OF VERMONT, has recently sold a 100 light plant to the Winnipesaukee Paper Company, at Franklin Falls, N. H., and a 100 light plant to the Fibre Wood Company, Plymouth. The Standard Company have a good dynamo, and are now making preparations to push it more energetically than ever during the summer and fall.

THE GOULD & WATSON COMPANY continue to manufacture a vast number of insulators in various forms out of their successful material, moulded mica, and report business as extremely brisk. Besides these insulators Messrs. Gould & Watson do an enormous business in mica, and are selling to all the electrical companies, for various purposes, being direct importers from India, of the very best quality for high insulating properties.

MR. W. H. CLAUSEN, electrician of the Boston office of the Gold and Stock Telegraph Company, has invented a new system of winding the small motors used for running the transmitters, which operate the numerous stock tickers in brokers' offices, by which he increases the efficiency of these motors to 90 per cent. The motors will run with 36 milliamperes of current, being only about one-sixth of the current hitherto used. The principle can be applied to all small motors up to one horse-power with good effect.

THE NEW ENGLAND WIRING AND CONSTRUCTION COMPANY are wiring the Ponemah Mills, Taftsville, Conn., for a 1,000 light Thomson-Houston plant, and are installing a commercial plant of 600 lights in Groveton, N. H., doing, besides, all the outside and inside wiring. They are also engaged in wiring Dr. Burgergreen's house in Lynn, Mass.; a private residence in South Framingham, Mass., in which the interior conduit system will be used; and are also fitting up the Temple Club, Boston, and a fine residence in the Back Bay district, Boston, with the interior conduit system, wiring and fixtures.

THE NATIONAL TELEPHONE MANUFACTURING COMPANY are creating quite a sensation and boom in their business by the wholesale distribution in post office boxes of what they term a National Mail Card. They are to be congratulated on their unique scheme of advertising, and the large amount of success which has recently attended them. Their business was never so good as at present, and they are sending their non-electric telephones, which time has proved to them to be most successful, not only all over this country, but to many foreign countries, where they are received with great satisfaction.

THE HOLYOKE MACHINE COMPANY, OF WORCESTER, Mass., have just completed large additions to their factory and foundry, and have built a new office and draughting room on the second floor. They are at present engaged in a great deal of heavy work in turbine wheels and shafting, and have recently equipped the electric railway stations in New Orleans, Indianapolis and Waltham, and only a short time ago finished equipping the Worcester electric light station, one of the finest electric light plants in the country. The Holyoke Machine Company do only first-class work, and are exceptionally well prepared to execute the largest orders on very short notice.

PETTINGELL-ANDREWS COMPANY.—The business of Messrs. Pettingell, Andrews & Company has been formed into a corporate company, and will hereafter be known as the Pettingell-Andrews Company. The company has been organized with a capital of $300,000, and the officers of the company are Mr. F. E. Pettingell, President; Mr. D. A. Andrews, Jr., Vice-President; Mr. D. A. Andrews, Treasurer, and Mr. C. B. Price, Secretary. The business of the company continues to increase at a very rapid rate, but they will still handle promptly all orders for electric light and railway supplies. They retain the sole and valuable agency of the Okonite wires and cables, which are becoming more popular than ever, and have recently been appointed New England and Eastern Canada agents of the Bryant Electric Company, of Bridgeport, makers of the famous Bryant switch.

SEEING BY ELECTRICITY.

A cable dispatch from London of July 5 says:—Prof. Hughes exhibited at the Penny Postage Jubilee a novel instrument which enables people using a telephone to see the speaker at the other end of the wire while talking and listening to him. This is accomplished by the appearance of an image of each of the speakers, which looks like an animated colored photograph. It is a very curious thing, and has attracted a good deal of attention.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, JULY 16, 1890. No. 115

The most important—not to say the only—rule for the genuine investigation of nature is to remain firm in the conviction that the problem before us is to learn to know phenomena, before seeking for explanations or inquiring after higher causes. As soon as a fact is known in all its relations, it is therein explained, and the problem of science is at an end.—Julius R. Mayer.

BANISHING THE STEAM PIPES.

AN order has been issued by the Board of Health to the New York Steam Company, to suspend its service at certain points on Broadway and Wall street. This action is taken as the result not only of the many recent accidents and explosions but of the facts as to dangerous heating of gas pipe joints, bad smells, escape of steam, etc., brought out by an investigation regarding the manner in which the system is working. It does not follow that the service in question will be suspended immediately, but it is not at all unlikely that hereafter there will be a decided restriction of the company's operations.

In this matter, as in most others of the kind, there has been much unfair complaint and exaggeration. Steam distribution has not been all that fancy formerly painted it; neither has it been quite a wholesale failure. In many respects it has been a success, but to-day it is not the necessity it once was. Except in a few instances where the steam is used for heating, it could be dispensed with, and its absence would not be felt or noticed, unless for the better. In other words, all the power service that is now being given over a large area by small steam engines can be given more safely, more cheaply, more expeditiously and more conveniently by electric motor. The steam mains are everywhere paralleled by electric mains; and while a partial rupture of the steam mains means a total disablement of large sections of supply, the electric circuits now so ramify and interlace that it daily becomes more improbable that even a single block could be cut off from its central station except by deliberate choice.

Moreover, as has just been remarked, the electric motor outranks these small engines in economy. It is simply true that while efficiency is not expected in a 1 or 2 h. p. engine, it is looked for and is obtained up to a very high point in electric motors of such a size. The charges for service will also stand comparison. We know of more than one instance of late, wherein the motor has supplanted the engine with an enormous saving to the user of the power. There are, of course, many incidental advantages, but the dollars-and-cents argument is the one that receives the greatest attention and commands the most respect. New York does not claim, however, to be singular in that regard.

For such reasons as have thus been intimated, it seems to us that the days of steam supply in this city are limited. Our excellent contemporary, the *American Gas Light Journal*, says that the troubles are due to the "infernal recklessness" of the Steam Heating Company; but the service may be bad and inadequate without being either "infernal" or "reckless;" and it will lose its patronage chiefly because a better method of power distribution has been found, namely, one of confining all the nuisances of steam generation and expansion to one central station, yet delivering its power instantaneously in any quantity at the point of consumption, in the guise of harmless current that has traversed a cold and silent wire the thickness of a lead pencil.

One point, however, has yet to be dealt with by electrical inventors and engineers. We refer to the use of the steam for heating as well as power purposes. This double necessity will not escape the notice of far sighted men; and then another step in advance will have been made.

ELECTRICITY IN METAL WORKING.

WHEN, some fifteen years ago, Sir Wm. Siemens constructed a small electric furnace and succeeded in melting steel by the heat of the arc, the possibility of applying the current for smelting purposes was accepted, but its practical application to any considerable extent was considered to lie far in the future. But in less than one-half of the usual time required for an idea to become firmly established and fruitful, we find the current applied in numerous instances for smelting purposes, principally for the production of aluminium. Going but a step beyond, we note its application to heating for the welding of metals.

To the electric drills now coming into general use must be added the electric riveter, a very ingenious arrangement which is described in another column. But the inventor, going still farther, applies the current not only to obtain the finished product, but to test it as well, after its completion. The most recent application of this kind, the schiseophone, which we illustrate elsewhere, is a beautiful combination of elements, both acoustic and electric, and has already found a field of usefulness, not merely in the testing of war material, but in one of the most important details of railway construction—the rails. With such an instrument in use in every bridge shop, there would be little excuse for bridge disasters, and the present method of testing one sample bar out of 50 or 100 will be looked back upon as a barbarism and a misdemeanor.

DEFECTS IN PHYSICAL TERMINOLOGY.

With the rapid strides that science has made during this century, it ought not to be a cause for wonder if many of the early explanations of physical phenomena varied considerably from those current to-day. But, on the other hand, it cannot be denied that even at the present time much diversity of opinion, not to call it uncertainty, exists on many important facts in physics; and the confusion is such as to require a thorough revision or unification of physical terminology. This is well shown in Prof. Dolbear's article on this subject on another page, in which he quotes from a variety of authors, no two of whom exactly coincide in the definition they give of the phenomenon of heat. This diversity exists in a like manner with reference to electricity. When to this is added Dr. Lodge's dictum that the very term "electricity" may have to go, in the light of future investigation, it will be seen that physical terminology, though sadly in need of standardization, as it were, may be a subject still allowing generous and even heterodoxical latitude of opinion. While, in this issue, merely pointing out the diversities and discrepancies existing, Prof. Dolbear in the succeeding part will show in what manner considerable uniformity may be attained in physical terminology based on well recognized phenomena or established theories.

THE RAILWAYS OF TO-MORROW.

The daily papers have been busily discussing during the past week a remark said to have been made by Mr. Henry Villard just before he sailed for Europe, that it would be well to go cautiously in respect to certain expenditures for locomotives, because it was probable that within a few years the motive power of every railroad in the United States would be changed. Our newspaper friends think that Mr. Villard is cognizant either of some new process for storing current or has had his attention called to some invention for generating current directly from the heat of fuel.

But neither of these alternatives or conjectures is necessary to explain Mr. Villard's remark—if he made it. There is surely enough promise in the work already done by electricity on street railways and long rural roads to warrant the utterances quoted, or something pretty near them. Already over 25 per cent. of the street railroads of the country are electrical, and this proportion is doubled among the new roads as they spring up. Another feature of the work is that many places now lying close together have each their electric roads and are being supplied with electric links, so that practically for miles and miles there is a continuous electric service.

We have heard during the past few days of a well matured plan for an electric road between two of our largest cities about a hundred miles apart. Along the line of that road are already several existing electric roads, and much less work than one would at first suppose is necessary to complete the whole track and make the supply of current uninterrupted from one end of the road to the other. On such a road, cars would be running all the day through, every few minutes, and a man who used it would no more be the slave of a time table than he now is if traveling on the New York elevated road or the Brooklyn horse cars.

CURRENT AND FRICTION.

The publication in our columns of the experiences and results obtained by various experimenters in the effects obtained by the passage of the current between two moving surfaces has encouraged others to experiment on similar lines, and in this issue we give the results of work done at the works of the Thomson Electric Welding Co.

It may probably be taken for granted that the increased friction noted is invariably accompanied by, and is due to, the generation of heat at the surfaces in contact; and this is confirmed by Mr. Schmidt, who shows that the attraction due to the electro-magnetic action is practically negligible. But it will be noted that Mr. Schmidt's results differ in some respects from those heretofore obtained and show that considerable difference exists between the "electric friction" of repose and that between moving bodies. Thus while the coefficient increased with increasing current with the surfaces in repose, it actually decreased with the surfaces moving. This latter result is in direct variance from the results obtained by previous experimenters, but attention must be drawn to the fact that Mr. Schmidt's experiments extended over a wider range of current and surface than has heretofore been employed and that they relate exclusively to surfaces in sliding contact. While we are not informed as to the maximum strength of current employed by Mr. Ries, the latter's work has been almost entirely confined to rolling surfaces, having but a mere line of contact and in which the current density must be exceedingly high. That there may be some differences due to these different contacts is not improbable, and further investigation in these directions is eminently desirable. Mr. Schmidt's results, however, agree with the phenomenon pointed out by Mr. Ries, that the oiling of the surfaces is followed by an increase in friction.

The Demand for Small Motors.

With the thermometer a hundred in the shade, it need not be wondered at that a gasping cry has been heard all over the country for electric fan outfits. The demand during the past week for small motors and fans has been almost fabulous, and not a manufacturer has been able to keep up with the orders raining in from every quarter. An order in the morning for a dozen motor outfits has been duplicated by telegraph at midday and quadrupled at night with an humble, heartrending supplication for immediate delivery.

Series Railway Data.

The data published so far relative to the power and current required by electric street cars operated in parallel is now familiar and gives a fair basis for the estimation of the plant necessary to operate such roads. But up to the present time no such data have been forthcoming with regard to cars operated on the series system, the small number of such roads being probably accountable for this. Our readers will therefore be greatly interested in the figures presented by Mr. O. T. Crosby in another column, giving the results of some tests made on the Short series railway at Huntington, W. Va. From these it will be noted that the consumption of power does not differ materially from that required by cars run in parallel on roads of similar character as regards gradients.

THE INFLUENCE OF CURRENT ON THE FRICTION OF SLIDING SURFACES.

BY LOUIS M. SCHMIDT.

The influence of the passage of current upon the friction of sliding surfaces was recently investigated at the laboratory of the Thomson Electric Welding Company, the currents employed being higher than are ordinarily used, except for welding purposes. An ordinary welder with very few changes constituted the principal part of the apparatus employed. The secondary of the welder consisted of almost a complete circuit of solid copper. The break was in a portion that was horizontal with a V-shaped cross-section, with the sides inclined 45 degrees from the vertical. The V on one side of the opening was directly in line with that on the other side, thus forming two sets of guides in line with one another.

At each side, supported by the guides, was a block of copper, V-shaped at the base to correspond with the guides. These blocks ordinarily support the clamps which hold the stock to be welded. These two blocks were united mechanically by cords and electrically by copper conductors made of copper strip. To the block on one side was attached a

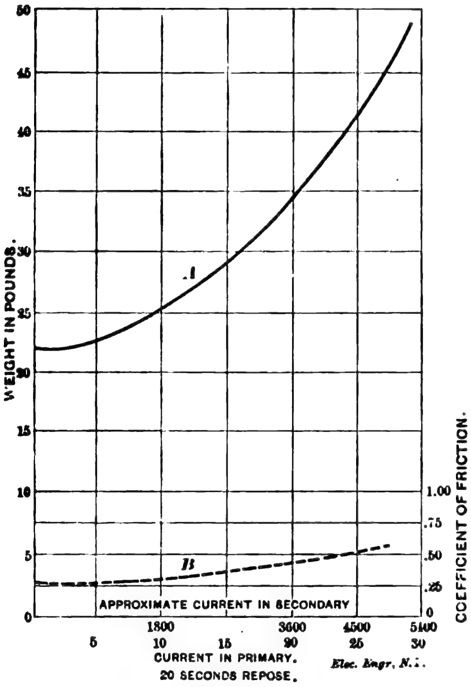

FIG. 1.

lever by a cord, by means of which the blocks could be drawn toward the corresponding end of the guides. To the other block was attached a cord which passed over a pulley. To the end of this cord was attached the weight required in a given case to overcome the friction and start the blocks in motion.

The current in the primary was read each time. The ratio of the turns in the primary to the turns in the secondary was 180 to 1. Assuming the ratio of the current in the primary to the current in the secondary to correspond to the ratio of the turns, the current in the secondary is thus approximately obtained.

Each contact surface contained 15 square inches of surface, making 30 square inches for each block, across which the total current in the secondary passed. Thus, with a current of 4,500 amperes, there would be 150 amperes per square inch of surface. The current used was of 100 alternations, or 50 periods per second.

In the accompanying diagrams the abscissæ represent current in primary or secondary as noted on the same. The ordinates for the full drawn curves, with dimensions on the left, represent the corresponding weight in pounds necessary to move the blocks. The ordinates for the broken line curves, below the full line curves, with the dimensions on the right, represent the coefficient of friction corresponding to the current as represented by the corresponding abscissæ. These values were obtained by dividing the weight required to move the blocks by the weight of the same, which was taken at 80 pounds.

Trials were made with, and without, repose, with quite different results so far as the investigation was extended. With repose of a few seconds with the current on, begin-

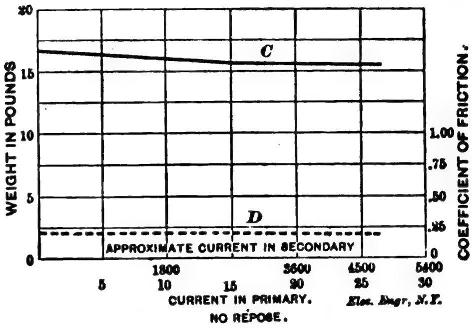

FIG. 2.

ning with the smaller currents and gradually increasing, the influence of the current at first was slight; but as the current was increased the influence increased at a rapid rate. The curve A, in Fig. 1, was plotted from results taken, allowing 20 seconds repose with the current on before the weights were applied. The corresponding coefficient of friction curve B is shown below A.

To investigate whether the influence was due to heating effects only, or was augmented by magnetic effects mani-

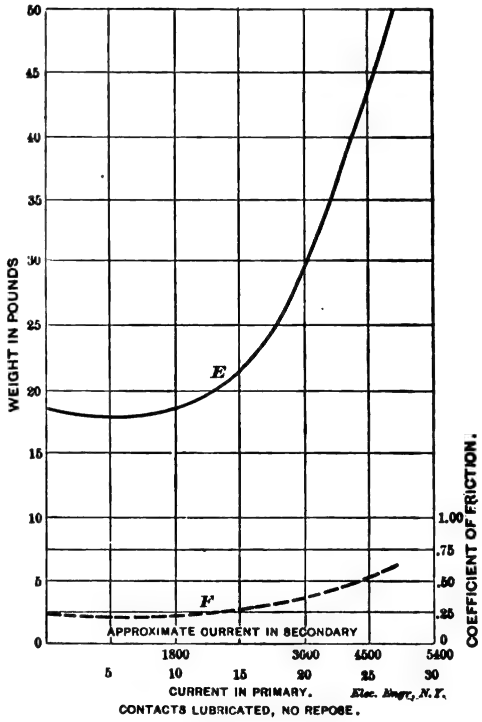

FIG. 3.

fested only while the current was flowing, a few trials were made leaving the current on during 20 seconds repose, but opening the circuit just before applying the weights. While it was found in a given case that the weight required was less than when the circuit remained closed, the difference was not more than might be attributed to loss of heating effect by the interruption of current.

Curve D, in Fig. 2 was plotted from results obtained without allowing repose. The influence of the current, so

far as tried, was slight, but, contrary to the previous case, it was found to decrease the friction.

Trials were also made with the contact surfaces lubricated. The lubricant used was mineral oil, such as is used for bearings. With comparatively small currents the influence was not appreciable. The turning point was, however, soon reached, when it was found that the rate of increase of the effect was rapid with a moderate increase of current. As the effect was quite variable, it was difficult to obtain very accurate results. Curve E, Fig. 3, however, shows very well the general tendency.

Results similar to the above were also obtained with the two blocks united by a piece of wrought iron held at the ends by the clamps which were on the blocks. Thus the iron formed both the mechanical and the electrical connection between the blocks. On account of the rigidity of the connection by this method, there was considerable liability at times that some of the surfaces might not remain in good contact even if once so arranged, for the effect of expansion of the stock due to heating and the mechanical strains to which the parts are subjected would have a tendency to throw the parts out of line. These objections are eliminated by the use of a flexible connection.

The deductions that may be made from the above results are that the influence of the passage of current upon the coefficient of friction for sliding copper surfaces is :

First, to increase the coefficient of friction of repose.

Second, to slightly decrease the coefficient of friction of motion within the limits tried, about 100 amperes per square inch of surface.

Third, that the effect of oil with other than weak currents relatively to cross-section of conducting surface would be to largely increase the coefficient of friction.

THE QUANTITY OF ELECTRICITY IN A LIGHTNING FLASH.

Assuming that a normal flash melts a copper conductor of 5 sq. mm. section, Prof. Kohlrausch proceeds to calculate the quantity of electricity involved. A metre of wire of this size weighs about 44.5 grammes, and 6,700 calories are required to raise it to the fusing point of 1,200° C. A conductor of 5 sq. mm. section and 1 metre in length has an average resistance of .01 ohm between 0° and 1,200°. A current, C, in time, t, will therefore develop in it $.24\ C^2 \times t \times .01$ calories. Now it may be assumed that t varies between .001 and .03. Assuming the quantity of heat to be 6,700 calories, we get for C 52,000 and 9,200, respectively, for the two values of t. The quantity of electricity would therefore be 52, or 270 coulombs, and would be sufficient to decompose 5 and 25 mgr. of water respectively. Or, taking another illustration, if the quantity of electricity could be stored and used to supply a 16 candle-power incandescent lamp, 35 and 7 of the flashes, respectively, would be required per hour. Palaz's investigations gave for a flash 28 coulombs.

VOLTMETER READINGS ON THE SHORT SERIES ROAD, HUNTINGTON, W. VA.

BY O. T. CROSBY.

The following voltmeter readings recently taken by me show the difference of potential between the terminals of a Brush motor, used for propelling a street car at Huntington, W. Va. This motor is in series with another similar motor propelling a second car, and in series also with a stationary motor and a special arc lamp. The current—furnished by a Brush dynamo—is nearly constant at 34 amperes. The car motor was mounted on the front platform, its horizontal plane of symmetry lying nearly in the plane of the car-floor. Spur-gearing connects the armature with the front car-axle. Rotation of the brushes around the commutator effects the desired variation of speed. Short-circuiting is resorted to for a long stop. Stopping just long enough to let one passenger get on or off quickly is effected by the brakes, the brushes being thrown into such position as to reduce torque. Readings were taken every 30 seconds with an Ayrton & Perry voltmeter graduated to 200 volts. Fair approximation can be made to 250. Occasional readings above that figure are rough estimations.

Length of run = 7.0 miles = 3.5 miles and return. Average speed = 8.4 miles per hour. Average number of passengers = 15. Approximate weight of car complete = 9,000 lbs. Maximum grade = 4% ; grades generally easy.

Track in good condition ; principally of T-rail.

Average d. p. = 155.5 volts. Average h. p. from wire to car = 7.07. H. P. hours per car mile = 0.84.

Similar figures for cars running "in parallel" have now been quite frequently presented. I have seen none for the few "series roads" in operation. Hence this communication.

THE SCHISEOPHONE.[1]

It is of vital importance in certain industries to be able to discover the flaws that exist in the interior of blocks of metal, and which, at a given moment, may put the security of a piece of work seriously in jeopardy. Hardened chrome steel shells, for example, present numerous centres of tension. The molecules, irritated against each other (so to speak) by the tempering, tend to separate and to leave spaces between them. Shells with such an internal structure are worthless, and their point breaks against the armor plate that they are intended to pierce. In most cases, there is nothing to indicate such flaws, and the human ear is too dull an instrument to perceive the differences in sounds given by the blow of a hammer, whether it be upon a perfect or a defective part. What has just been said about shells applies to all pieces of metal that are to be worked—gun tubes, axles, driving-shafts, rails, etc.

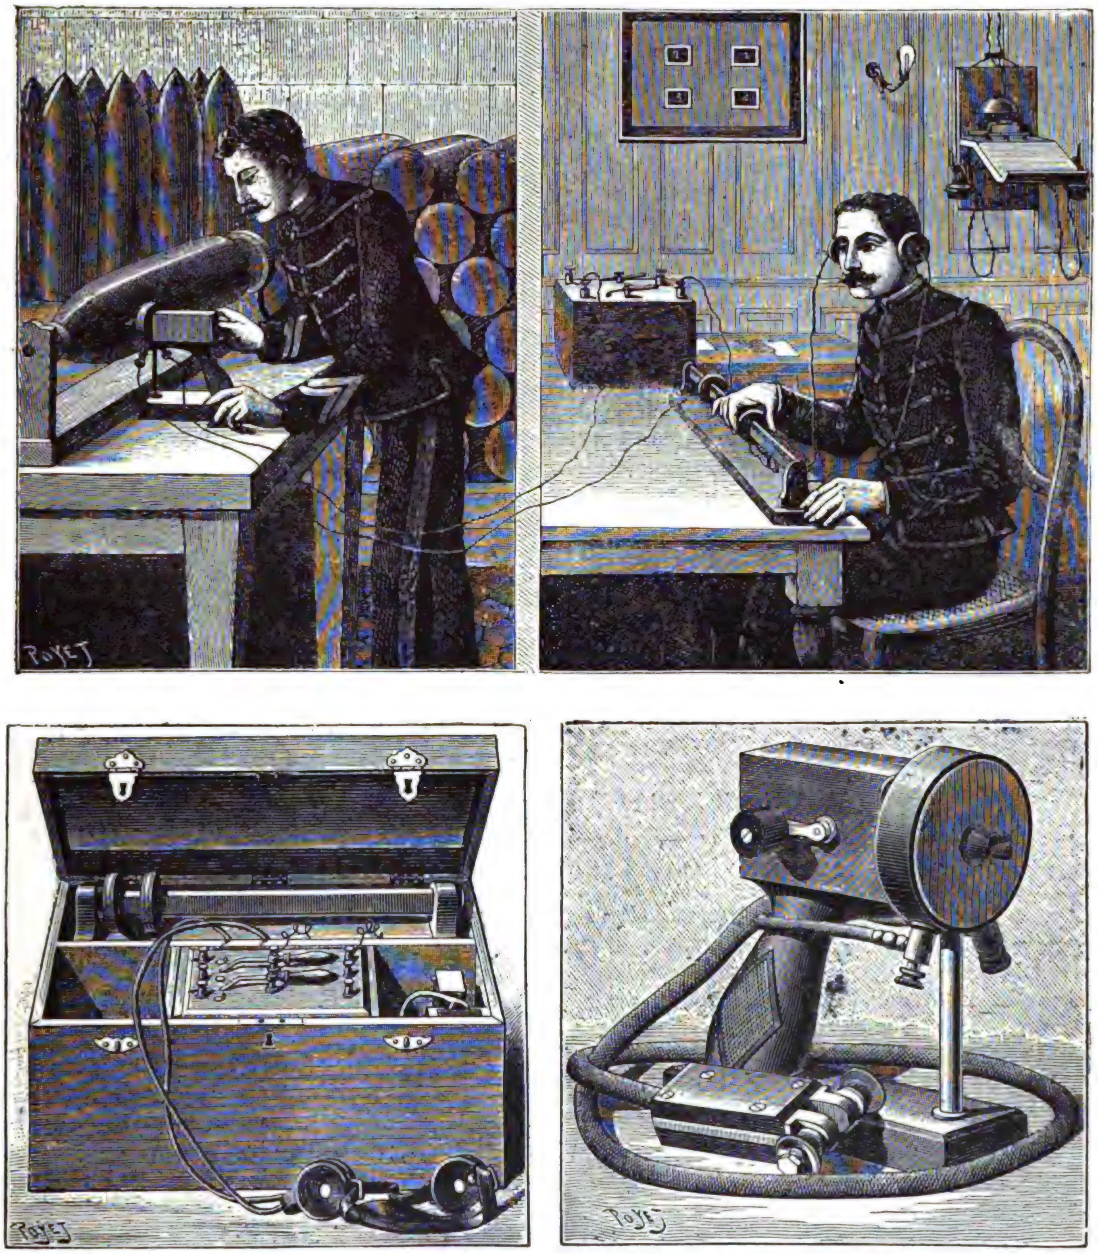
Captain Louis De Place, professor of fortifications and of applied sciences at the School of Cavalry, has had recourse to the microphone, employed under certain conditions, for the detection of flaws in metals. His apparatus, as will be seen, is an ingenious application of Prof. Hughes' induction balance. Captain De Place, combining the mi-

1. *La Nature.*

crophone with a mechanical striker and a sonometer, has produced an instrument which he calls a schiseophone (from Gr. σχίσις, "fissure," and φωνή, "sound" or "voice"), which permits of recognizing the difference in sound given by the striker, whether it strikes a perfect or an imperfect part.

The diagram, Fig. 4, shows the operation of the apparatus in the verifying room and the listening chamber is represented in Fig. 2. At B we have the block to be examined, and in which we shall suppose that there is a flaw, *t*. A microphone of annular construction and of special form is traversed by the striker, F, which is actuated by a very sound that will continue to diminish in measure as the operator widens the space between the coils. At a given moment, perfect silence will be obtained. If the examination be continued with the mechanical striker, and the latter hits at *p′*, a place where there is a flaw such as *t*, the interior flaw or vacuity will form a sounding box, the sound will increase, the microphone will cause the resistance of the external circuit to vary, and the sound will be re-established in the telephones. The internal flaw will therefore be made known.

The schiseophone is inclosed in a box, Fig. 3, having four compartments which contain (1) the audiometer and



FIGS. 1, 2, 3 AND 5.—THE SCHISEOPHONE, OR DETECTOR OF FLAWS IN METALS.

simple mechanism (not shown) that gives it an alternate to and fro motion. A battery, P, is placed in the circuit of the microphone and of an inducing coil, B, fixed to the zero point of a graduated rule, R R′. Upon this latter moves the induced coil in whose circuit there is a pair of telephones provided with a spring that permits of fixing them upon the head.

It will now be understood that if the striker hits a perfect part such as *p*, the induced coil, being in contact with the inducing one, the telephones will produce a certain its bobbins; (2) the telephones; (3) the striker and its microphone; and (4) six dry elements of the De Place type. These elements are in threes in series, and a commutator upon the cover permits of changing the batteries every quarter of an hour in order to prevent polarization. The special absorbent discovered by Captain De Place, and called *melasine* by him, presents no internal resistance. It does not dry up, prevents climbing salts, and keeps the zincs in a permanently clean state.

Some experiments were recently made at Ermont, the

stock depot of the Northern Railway Co. The schiseophone was kept in operation for a whole week, showing the company's engineers the internal flaws in rails. The location of the flaws was at once marked with red paint. In the afternoon, the rails were broken by a power hammer at the places indicated, and, in every instance, the breakage brought fissures of more or less importance to light.

In order to get proper indications from this instrument, it is important that the same operator shall always have the telephones, and that the apparatus be so maneuvered as to permit the striker to rebound upon the metal. Finally, in practice, it is preferable not to draw back the induced coil

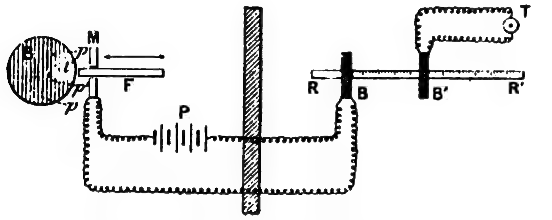


FIG. 4.—CIRCUIT OF SCHISEOPHONE.

until perfect silence is obtained, but to allow a slight sound to remain in the telephone. It is the increase of such sound that reveals the internal flaw.

It will be easily conceived that it is of prime importance for railway companies to have none but sound rails. The defective ones break and cause derailments, which, aside from the personal accidents that accompany them, prove very expensive both on account of the indemnities to be paid and of the deterioration of the *materiel*. The schiseophone provides a remedy for this.

THE SANFORD ELECTRIC PROTECTOR.

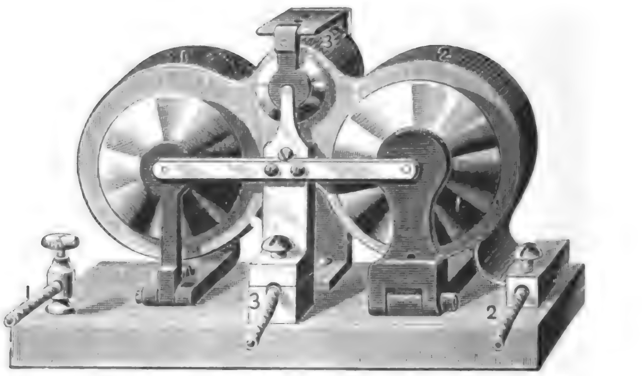
THE introduction of electric light and power circuits soon made it apparent that where these lines ran in proximity to telephone, telegraph or fire alarm wires, means had to be provided for protecting the instruments connected with the latter from the effects of crosses. The heavy currents coming in led to frequent destruction of the more delicate instruments and a variety of safety devices have been designed to prevent this, embodying safety-fuses and cut-outs of various types.

A recent instrument designed for this purpose by Mr. C. E. Sanford embodies a number of novel features which make it worthy of notice and in which the aim of the inventor has been to provide an apparatus which shall have a large range of action so as to protect for the smallest as well as the heaviest currents, and which at the same time is always ready for action without requiring any attention whatever.

The manner in which these requirements are fulfilled is shown in the accompanying engraving which illustrates the Sanford protector. As will be seen, it consists of three coils, 1, 2 and 3, each of which is wound with a different sized wire, and so arranged that they will attract their respective armatures with different strengths of current. Thus the incoming wire enters at the binding post 2, passes through the coil 2 and is then connected to the core of that coil. The frame is bent around in U-shape, and has hinged to it the armature of coil 2. From the frame of coil 2, the circuit passes to coil 1, is connected to its core and armature in a similar manner, and from there the circuit leads to and through coil 3 and out at binding post 1 to line.

The small coil 3 is wound so as to attract its armature when the current reaches ¼ ampere and maintains its connection until the current reaches 4 amperes. The coil 1 attracts its armature at 2 amperes and protects up to 30 amperes; while coil 2, which is wound with heavy copper ribbon, begins to act at 20 amperes, and has a capacity of 250 amperes.

The action of the instrument results in the cutting out of the apparatus to be protected by shunting or grounding, and this is accomplished in the following way. It will be noticed that the ends of the coils are embraced by, but insulated from, a spectacle-shaped copper plate which is supported by, and in metallic connection with, the standard 3 connected to ground. Now, supposing that a cross occurs on the line to be protected, and a current of more than normal strength comes in. It passes in succession through coils 2, 1 and 3. As soon as it attains a strength of ¼ ampere it attracts the armature of coil 3 which comes in contact with the grounded plate and thus carries the current off around the instrument to be protected. Now, if the current should increase, at the instant it reaches 2 amperes, the armature of coil 1 is attracted to the ground plate, which action not only cuts out the instrument to be protected, but at the same time shunts the fine coil 3, thus protecting it also from destruction. When the current



SANFORD ELECTRIC PROTECTOR.

has reached 20 amperes, finally, coil 2 comes into action, and similarly cuts out both the other coils, whose armatures drop back to their original positions. As coil 2 is capable of carrying a current of 250 amperes, it is evidently able to take care of the heaviest stray current which is likely to come in on any line.

It will be evident from the construction, that as soon as the stray current is removed from the circuit, the instrument assumes its original condition, takes off the ground, and is ready for the next operation.

We have seen the instrument in operation at the office of the National Electric Protector Co., of this city, of which Mr. C. E. Sanford is the lessee, and had occasion to witness it act under a variety of conditions with eminently satisfactory results. As the entire resistance of the protector is less than one ohm, it entails practically no deterioration of the service, while, as was demonstrated, it is able to protect both sides of the system.

A PREDICTION OF THE PHONOGRAPH.

THE Baroness Althea Salvador, in a recent letter to one of the New York papers, from Paris, says:—"'There is nothing new under the sun!' one cannot help exclaiming after reading the proofs of Louis Pauliat, Senator, that the phonograph was known in 1650. In this year Cyrano de Bergerac, an author and famous duellist wrote, 'A Journey in the Moon.' His guide, obliged to leave him some moments, lends him two books, and Cyrano de Bergerac takes one which has a cover like a box. Here it is.

"At the opening of the box I found I know not what, in metal, full of little springs and imperceptible machines. It is a book, but a miraculous book, with neither leaves nor characters; it is a book to read which eyes are useless, for one needs only ears. When I wished to read, I bound the the box with all kinds of little nerves that I found, then I turned the needle on the chapter to which I wished to listen, and I heard, as from the lips of a human being, most remarkable facts of intense interest to a student."

According to M. Pauliat here is the description of a

phonograph similar to the one invented by Mr. Edison. It will be remembered that like fanciful anticipations were made of the telephone.

ON THE RECTIFYING OF ALTERNATE CURRENTS BY SYNCHRONIZING DEVICES AND THE INFLUENCE OF SELF-INDUCTION THEREON.

BY CHAS. STEINMETZ.

It is well-known that a current which has always the same direction can easily be derived from an alternate current circuit by means of a synchronyzing device; that is, a commutator whose revolutions have a constant ratio with the periods of the alternate current, and which may be set and kept in synchronism by this same current.

But the derived current, although often miscalled a continuous current, differs considerably from the continuous currents of our dynamos, its value varying between zero and a maximum. Therefore it may be more properly called a *pulsating current.*

While on a true continuous current circuit self-induction will have no influence at all; on such a pulsating current the counter electromotive force of self-induction will cause a series of phenomena, the worst of which will be excessive sparking at the commutator, especially when the pulsating current is used for exciting electro-magnets.

Such pulsating currents are largely used for exciting the electro-magnets of so-called self-exciting alternate current generators, and also of synchronous motors, like that of Ganz & Co., which has attracted considerable attention lately, since the competitive tests at Frankfort-on-the-Main proved its efficiency to be very satisfactory.

Very little is known as yet of the behavior of these pulsating currents. Only a short time ago it was wrongly asserted before a meeting of expert electricians, that the magnetism of electro-magnets, which are excited by pulsating currents, could sometimes become zero, whereas the truth is, that the value of the magnetism will oscillate around the average or mean value of the magnetizing current, with an amplitude more or less diminished by self-induction; therefore, in the alternate current transformer it will pass through zero twice in each period (zero being the average value of the alternate current), but in the electro-magnets excited by a pulsating current it can never become zero, the mean value of the current being a value different from zero; the oscillations of the magnetism would just touch the zero line, if their amplitude were not reduced by self-induction. It seems to be worth while, therefore, to subject these pulsating currents, and the phenomena connected therewith, to an analytical treatment.

In order to consider what happens in such an electric circuit, let us first suppose the electromotive force of the dynamo-generator (the impressed electromotive force of the circuit) to be a true sine curve, and leave out of consideration the influence of hysteresis and of eddy-currents.

The time t may be counted from the moment when the value of the impressed electromotive force equals zero, the time of one-half period being $= T$, corresponding to an angle of 180°, if we represent the whole period by one revolution, or 360°.

Then the equation of the impressed electromotive force is:

$$e_0 = E_0 \sin \pi \frac{t}{T}, \qquad (1)$$

where E_0 means the maximum value of the impressed electromotive force of the dynamo; for the sine curve $E_0 = C_0 \sqrt{2}$, C_0 being the "effective" electromotive force of the dynamo.

Now the connection and disconnection of the electro-magnet with the main-circuit, that is, the commutation of the current, can be done either by breaking or by short-circuiting both the electro-magnet and the main line at the moment of commutation. In the latter case a suitable resistance can be thrown in both circuits.

It does not seem likely that anybody would risk the breaking of the current, just when the electromotive force of self-induction is near its maximum value. But the only possible and practical method, which shall be considered here, seems to be as follows:—

1. To establish the connection between the electro-magnet and the main line at the time T_1, corresponding to an angle φ_1;
2. To short circuit both the electro-magnet and the main line by means of the commutator brushes and through a suitable resistance, at the time T_2, corresponding to an angle φ_2;
3. To take off the short circuit and establish the first connection again, at the time $T + T_1$, corresponding to an angle $180° + \varphi_1$, and so on.

The current, the magnetism, the resulting or current-producing (heating) electromotive force, the counter electromotive force of self-induction, may be represented by the symbols c, m, e, e_i, respectively; their maximum values by the capitals C, M, E, E_i.

Let the magnetic resistance of the electro-magnetic circuit $= \rho$.

Let the number of magnetizing turns $= n$.

Then the coefficient of self-induction $\mathbf{K} = \frac{n^2}{\rho} 10^9$ henry[1].

Let the electric resistance of the magnet circuit $= r\,\Omega$.

Let the electric resistance of the main circuit $= r_0\,\Omega$.

Let the short-circuiting resistance $= R\Omega$;

then the magnetism (number of lines of magnetic force, or, more correctly, tubes of magnetic induction) is:—

$$m = \frac{n\,c}{\rho}; \qquad (2)$$

the induced electromotive force (self-induction):—

$$e_i = -\,n \frac{d\,m}{d\,t} .10^{-8} \text{ volts}; \qquad (3)$$

the resulting electromotive force:—

$$e = e_0 + e_i = E_0 \sin \pi \frac{t}{T} - n \frac{d m}{d t} .10^{-8} \text{ volts}; \qquad (4)$$

and the current:—

$$c = \frac{e}{r + r_0} = \frac{E_0 \sin \pi \frac{t}{T} - n \frac{d\,m}{d\,t} .10^{-8}}{r + r_0} \text{ amperes.} \qquad (5)$$

Combining (2) and (5), we find:—

$$m = \frac{n}{\rho\,(r + r_0)} \left\{ E_0 \sin \pi \frac{t}{T} - n \frac{d\,m}{d\,t}\, 10^{-8} \right\} \qquad (6)$$

as the differential equation of the magnetism during the time from T_1 to T_2.

This differential equation is integrated by the function:—

$$m = A \sin (\pi \frac{t}{T} - \omega) + B\,e^{-\Sigma t} \qquad (7)$$

the constants of which are obtained by substituting the value m of equation (7) in equation (6).

$$\text{Since, } \frac{d\,m}{d\,t} = \frac{\pi}{T} A \cos (\pi \frac{t}{T} - \omega) - \Sigma\,B\,e^{-\Sigma t},$$

we get:—

$$A \sin (\pi \frac{t}{T} - \omega) + B\,e^{-\Sigma t} = \frac{n}{\rho\,(r + r_0)} \left\{ E_0 \sin \pi \frac{t}{T} - \frac{n\,\pi}{T} A \cos (\pi \frac{t}{T} - \omega) .10^{-8} + n\,\Sigma\,B\,e^{-\Sigma t} .10^{-8} \right\}$$

which equation is satisfied for any value of t, when:—

1. I do not think it necessary, in an American journal, to give an explanation for using the term "henry" as the practical unit of self-induction, instead of the "quadrant."

$$\left.\begin{aligned} A\cos\omega &= \frac{n}{\rho(r+r_0)}\cdot\left\{E_0-\frac{n\pi}{T}A\sin\omega\,.10^{-8}\right\};\\ A\sin\omega &= \frac{n}{\rho(r+r_0)}\cdot\frac{n\pi}{T}A\cos\omega\,.10^{-8}\\ B &= \frac{n}{\rho(r+r_0)}\,n\,\Sigma B\,.10^{-8}. \end{aligned}\right\}$$

From this we have :—

$$\left.\begin{aligned} A &= \frac{n\,E_0}{\sqrt{\rho^2(r+r_0)^2+\dfrac{n^4\pi^2}{T^2}.\,10^{-16}}};\\ \tan\omega &= \frac{\pi n^2.10^{-8}}{\rho(r+r_0)\,T};\\ \Sigma &= \frac{\rho(r+r_0)\,.10^{-8}}{n^2}=\frac{\pi}{T}\cos\omega; \end{aligned}\right\} \quad (8)$$

B being still unknown.

From this, we get the magnetism at the time T_1 :—

$$M_1 = A\sin(\varphi_1-\omega)+B\,e^{-\Sigma T_1} \quad (9)$$

and at the time T_2 :—

$$M_2 = A\sin(\varphi_2-\omega)+B\,e^{-\Sigma T_2} \quad (10)$$

A, ω and Σ, being already known,

$$\varphi_1=\pi\frac{T_1}{T}=\frac{T_1}{T}.180^\circ.\quad \varphi_2=\pi\frac{T_2}{T}=\frac{T_2}{T}.180^\circ. \quad (11)$$

During the time of short-circuit, from $t=T_2$, to $t=T+T_1$, the inductional electromotive force is :—

$$e_i^1 = -n\frac{d\,m^1}{d\,t}.10^{-8}\text{ volts}; \quad (12)$$

and the current :—

$$c^1=\frac{e_i^1}{r+R}=-\frac{n}{r+R}\cdot\frac{d\,m^1}{d\,t}.10^{-8}\text{ amperes.} \quad (13)$$

Therefore the magnetism is :—

$$m^1=\frac{n\,c^1}{\rho}=-\frac{n^2}{\rho(r+R)}\cdot\frac{d\,m^1}{d\,t}.10^{-8}; \quad (14)$$

which integrated gives :—

$$m^1 = M_2\,e^{-\Sigma^1(t-T_2)}, \quad (15)$$

where :— $$\Sigma^1=\frac{\rho(r+R)\,.10^{-8}}{n^2}, \quad (16)$$

since for $t=T_2$, m^1 must equal M_2.
Therefore for $t=T+T_1$,

$$m^1 = M_2\,e^{-\Sigma^1(T+T_1-T_2)}. \quad (17)$$

Now, at this moment, the electro-magnet is connected again with the main circuit, and therefore, in stationary condition, the magnetism again equals M_1.

This, together with (9), gives us the equations necessary for determining B :—

$$A\sin(\varphi_1-\omega)+B\,e^{-\Sigma T_1}=$$
$$\left\{A\sin(\varphi_2-\omega)+B\,e^{-\Sigma T_2}\right\}.\,e^{-\Sigma^1(T+T_1-T_2)},$$

from which :

$$B=A\frac{\sin(\varphi_2-\omega)-\sin(\varphi_1-\omega)}{e^{-\Sigma T_1}-e^{-\Sigma T_2-\Sigma^1(T+T_1-T_2)}}. \quad (18)$$

Now, everything being known, we can investigate the behavior of the current.

Between T_1 and T_2, the current is given by equation (2)

$$c=\rho\frac{m}{n};\text{ or,}$$

$$c=\frac{\rho}{n}A\sin\left(\pi\frac{t}{T}-\omega\right)+\frac{\rho}{n}B\,e^{\Sigma t}\text{ amperes.} \quad (19)$$

Between T_2 and $T+T_1$ the current in the electro-magnet is given by equation (12)

$$c^1=\frac{\rho\,m^1}{n};\text{ or,}$$

$$c''=\frac{\rho}{n}M_2\,e^{-\Sigma^1(t-T_2)}\text{ amperes}; \quad (20)$$

and at the same time in the main circuit :

$$c''=\frac{e_0}{r_0+R}=\frac{E_0}{r_0+R}\sin\pi\frac{t}{T}\text{ amperes.} \quad (21)$$

A very interesting conclusion in regard to sparking at the commutator can be drawn from the equations (19) to (21) :

It is obvious, that sparking at the commutator must disappear entirely if the short circuit has no current just at the moment of its breaking; that is, when at the time, $t=T_1$, $c^1=c''$.

This gives the equation :

$$\frac{\rho}{n}M_1=\frac{E_0}{r_0+R}\sin\pi\frac{T_1}{T}. \quad (22)$$

On the other hand, there will be given no cause for disturbances in the main line nor in the electro-magnet circuit, if the short circuit, applied at the time T_2, is without current in the first moment, so that neither the current in the main line, nor in the electro-magnet is affected; that is, when, at the time $t=T_2$, $c^1=c''$.

This gives the equation :

$$\frac{\rho}{n}M_2=\frac{E_0}{r_0+R}\sin\pi\frac{T_2}{T}. \quad (23)$$

These two equations (22) and (23) give us the two moments, T_1 and T_2, between which the commutation of the current has to take place, in order to avoid sparking at the commutator, and extremely rapid changes of the main current, and gives us thereby the width of the commutator-bars and of the gap between adjacent commutator-bars.

I am told that the above mentioned synchronous motor of Ganz & Co. owes its sparkless running to a similar arrangement. Besides this, the average magnetism, and the energy of the current, is much higher in circuits of this kind, as the accompanying diagrams (Figs. 1 and 2) show, which represent some curves of magnetism excited by such pulsating currents.

In Fig. 1,
the number of exciting turns, $n=200$.
" impressed electromotive force : $C_0 = 71$ volts (effective); therefore,
" maximum impressed electromotive force : $E_0=100$ volts.
" electric resistance of the field-magnet circuit: $r=5\,\Omega$
" " " " " main line: $r_0 = 10\ \Omega$.
" " " " " short circuit : $R=0$.
" magnetic resistance of the electro-magnet : $\rho=0.01$.

Therefore, the coefficient of self-induction : $\mathbf{K}=\frac{n^2}{\rho}.10^{-9}=$ 0.004 henry.
the time of half a period : $T=0.005$ second.
" " " connecting the electro-magnet with the main line : $T_1=0.0007$ second.
" time of short circuiting the electro-magnet and the main line : $T_2=0.00415$ second.
Therefore,
$A=68{,}000$.
$\tan\omega=1.676$. Angle $\omega=59^\circ$.
$\Sigma=375$.
$\Sigma^1=125$.
$M_1=\ 84{,}000$ lines of magnetic force.
$M_2=102{,}000$ " " "
$B=163{,}000$.

Therefore :

between T_1 and T_2: $m = 68{,}000 \sin (36{,}000\, t - 59)^\circ + 163{,}000\, e^{-375t}$.

between T_2 and $T + T_1$: $m_1 = 102{,}000\, e^{-195(t-0.00416)} = 171{,}000\, e^{-195t}$.

between T_1 and T_2: $c = 3.4 \sin (36{,}000\, t - 59)^\circ + 8.1\, e^{-375}$ amperes.

between T_2 and $T+T_1$: $c^1 = 8.6\, e^{-195}$ amperes in the electro-magnet,

$c'' = 10 \sin (36{,}000\, t)^\circ$ amperes in the main line.

At the time T_1: $c = c^1 = c'' = 4.2$ amperes.

At the time T_2: $c = c^1 = c'' = 5.1$ amperes.

In the diagram, Fig. 1, c, c^1, c'', and m, m^1 are the curves of the current and of the magnetism respectively; a is the curve, which the current would follow, if there were no self induction at all; b is the curve of the current and of the magnetism, if there were no commutation of the current, but the magnetism would reverse alike in the transformer. As shown in this latter case, the mean magnetism and the mean current is only about one-third of the value of that obtained by commuting the current.

In the moments T_1 and T_2 there is no discontinuity, and the short circuit being currentless, also no cause for sparking.

It will be seen that the magnetism and current follow a slightly undulating line, which would be still more like a straight line if the self-induction were higher.

In the diagram, Fig. 2,

$$r_0 = 5\,\Omega.$$
$$\rho = 0.05.$$
$$\mathbf{K} = \frac{n^2}{\rho}.10^{-9} = 0.0008 \text{ henry.}$$
$$T_1 = 0.001. \qquad T_2 = 0.004.$$

The other values are the same as in diagram, Fig. 1; therefore :

$m = 36{,}000 \sin (36{,}000\, t - 27)^\circ + 12{,}000\, e^{-1350t}$.

$m^1 = 388{,}000\, e^{-625t}$.

$c = 9 \sin (36{,}000\, t - 27)^\circ + 3\, e^{-1250t}$ amperes.

$c^1 = 48.5\, e^{-625t}$ amperes.

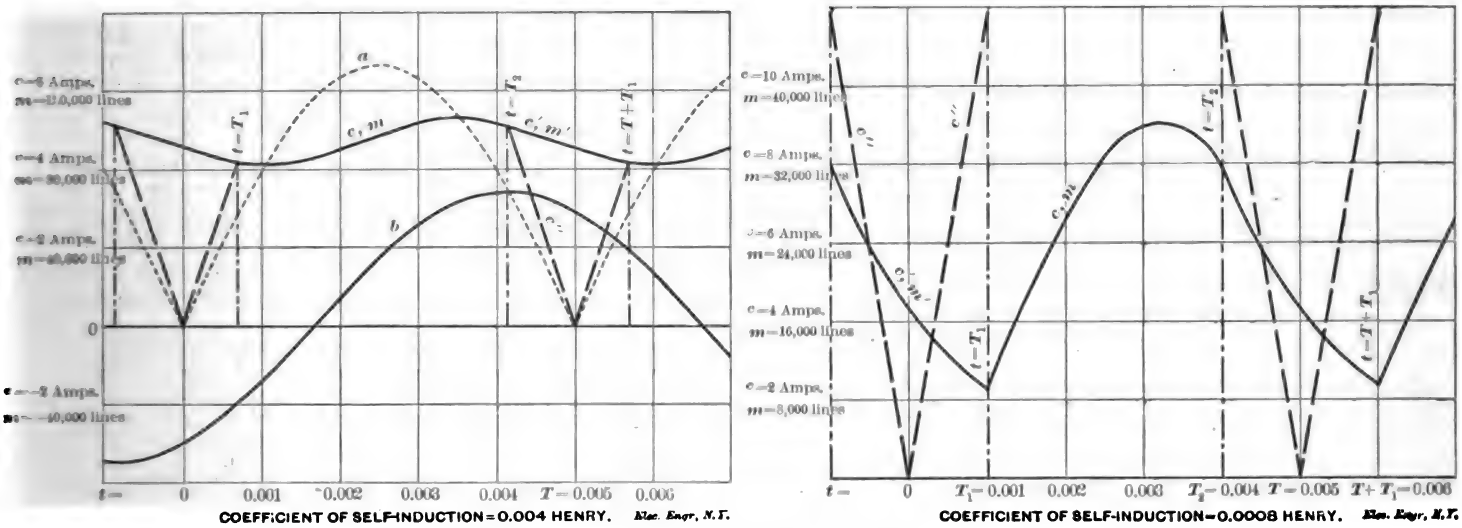
$c'' = 20 \sin (36{,}000\, t)^\circ$ amperes.

At the time T_1: $c = c^1 = 2.3$ amperes; $c'' = 11.8$ amperes.

At the time T_2: $c = c^1 = 8$ amperes; $c'' = 11.8$ amperes.

Here, the self induction being much smaller, the vibrations of current and of magnetism in the electro-magnet are much greater. But the most interesting fact is, that the short-circuiting of the electro-magnet, and the breaking of this short-circuit take place in wrong positions, and in the moment T_2 the main current has to jump from 8 amperes to 11.8 amperes; in the moment T_1 from 11.8 amperes to 2.3 amperes; and because at this moment there flows a current of 11.8—2.3 = 9.5 amperes through the short circuit under the brushes, the breaking of this current will cause an excessive and destructive sparking at the commutator-brushes. Besides this, the curve of the magnetism shows breaks at the points T_1, T_2, $T+T_1$, etc.

The commutator would indeed be improved by throwing a resistance R into the circuits between T_2 and $T+T_1$, but this would not stop sparking entirely.



FIGS. 1 AND 2.—STEINMETZ ON THE RECTIFYING OF ALTERNATING CURRENTS.

SOME DEFECTS IN PHYSICAL TERMINOLOGY.—I.

BY PROF. A. E. DOLBEAR.

THE science of physics is concerned with the conditions of the transference and transformation of energy wherever they occur, and for that reason it is not infrequently called the science of energy. Within the past fifty years a vast amount of attention has been given to the phenomena in different departments of physics; especially is this true of molecular phenomena, and our knowledge of it is really extensive. At the same time there has been a serious lack of coördination among the different departments exhibited in late treatises that form a real hindrance to one who would obtain a fair view of what is really known. Whewell attributes the failure of the Greeks to make headway in physical science, to the fact that their ideas were not appropriate to the phenomena. In a like manner it may be said that we are retarded by the lack of appropriate terminology, and that something will be gained when the terminology is so far reconstructed as to be incapable of misleading one.

First, as to the nature of energy. In Daniell's "Text-book of the Principles of Physics" the statement is made that "energy is a physical entity," implying that it is an independent, objective something, an existence not conditioned by other physical things, and this idea is so common that it is worth while to closely inspect it. Now energy is defined as the ability to do work, and work is measured in foot pounds. When we give expression to the relation between energy and work we have, $\frac{M v^2}{2} = W h$, when M is the mass, v the velocity, W its weight and h the height to which W will be raised. But $\frac{M v^2}{2}$ is the measure of energy in the units of work. In absolute units it is proportional to $M v^2$, or, as it is perhaps better to write it, $M v \times v$, which is the *velocity of momentum.* As there is

no such thing known as energy where there are not two factors, namely, a something—a real entity—and a motion, it follows that when there is absolute quiescence there is no energy, and if there be no substance, though velocity be infinite, there is no energy. Hence energy is a *product* and is not a something that exists apart from moving bodies. It is a product of substance and motion, and is proportional to the amount of motion. No body moves in any manner whatever except as antecedent motion has been spent upon it, and if one would seek for the origin of the motion of any mass of matter he might trace it never so far back only to find an antecedent motion; and on the supposition that the physical universe is infinite in extent then the amount of motion is also infinite, as well as the energy.

There is then no good reason for considering energy as being a mysterious something that has an existence apart from the substance of the physical universe any more than there is for considering the same for motion or for momentum.

Second. It appears that the so-called *forms of energy* depend upon the form of the motion involved as well as the character of that which is moved. As to the first of these, the kinds of motion, that are possible, are probably very great in number, but they may all be reduced to their primary forms, namely rectilinear, vibratory and rotary. Combinations of these yield all sorts of others. For instance, two rectilinear will give either a resultant rectilinear, as exhibited in the so-called parallelogram of forces, or a curvilinear, as in the movement of a bullet fired from a gun in other than a vertical direction. A combination of a rectilinear with a vibratory gives an undulatory or wave motion; a rectilinear with a rotary gives a spiral, and so on.

The expression for the energy of a body is not limited by the size of the body. It is as applicable to an atom as to a cannon ball or the earth in its orbit, but it is convenient to change the form of it where the physical conditions warrant it. For rectilinear motions or combinations of them the form $\frac{Mv^2}{2}$ is used for both large and small bodies, only such motions of atoms and molecules are called free paths, or the distance between successive impacts. It is not inappropriate to speak of the motions of larger bodies, as for instance that of a musket bullet towards a target, as its free path. In either case v is simply the rate of motion.

For vibratory motion, however, the value of v depends upon two conditions, the number of vibrations per second, n, and the amplitude of the vibration, a. These are entirely independent of each other, and either may have almost any assigned value, so that $v = a\,n$, and the energy is $\frac{M a^2 n^2}{2}$.

For a rotating particle, energy $= \frac{M r^2 \omega^2}{2}$, where r is the distance to the centre of rotation and ω is the number of degrees passed over in one second. It may have substituted for it the expression for rectilinear energy by making v the number of feet passed over in a second.

When the moving body is so large that its motions may be seen, the body is said to have *mechanical* motion or mechanical energy, sometimes kinetic energy, and when the body is too small to be seen the movements are spoken of as atomic or molecular; and here is where trouble often begins, by failing to keep in mind that the size of a body makes no difference in the character of the motions it may have.

Suppose a bell or tuning fork, or any elastic body, be suspended in the middle of the room, and it be struck by a body in any convenient way, vibrating motions will result that we should interpret as sound, and at the same time a free path motion would be set up, which would be restrained by the support so as to become oscillatory if it be no longer interfered with. Precisely similar conditions obtain when an atom or a molecule of air or other gas is made to vibrate by impact. It vibrates at its own harmonic rate and also moves in a free path till a collision occurs which changes its direction in its free path and interferes with its internal vibration. The swinging tuning fork gives out its proper sound, but we never think of speaking of its free path motion as a part of its sound motion. Whether it swings or not, is quite immaterial. Of course if it swings while it vibrates it possesses more energy than if it vibrated only, but the energy could not be spoken of as sound energy. No more should the free path movements of molecules, be they long or short, be called heat motion. This needs a little fuller development.

For twenty-five years or more we have been familiar with the expression, "*Heat is a mode of motion*," and lately we have it in numerous works intended to be exact that "*Heat is a form of energy*." To illustrate the fogginess upon this matter, I cannot do better than to quote statements from several text books lately issued. In Daniell's "Principles of Physics," p. 325, there is the definite statement in large print, "*Heat is a form of energy*." On p. 326 is this statement, "Heat is not motion;" and on p. 444, "The molecular vibration which excites ether waves is a true vibration of the molecule, not a transtational oscillation from place to place." Olmstead's "College Philosophy" (Kimball's revision) has it, "There is abundant reason for believing that heat consists of exceedingly rapid vibrations of ordinary matter and of the ether which fills all space." In Avery's "Elements," "Heat is a form of energy. It consists of vibratory motions of the molecules of matter." In "National Philosophy," by Sharpless and Phillips, "Heat like light, consists of waves of ether." In Gage's "Elements of Physics," "Heat is molecular motion." In "The New Physics," by Trowbridge, there is the statement that "motion is therefore being continually changed into heat in all the operations of machines." Also, "The phenomena of heat and light are so closely allied that it is impossible to regard them as separate manifestations of energy."

Maxwell says: "Heat is of the same nature as mechanical work, that is, it is one of the forms of energy." Also, "We have no right to speak of this process of radiation as heat," and again, "Heat can be generated and it can also be destroyed." "For every foot-pound of work so done, a certain quantity of heat is put out of existence."

These quotations are quite sufficient to show that there is no agreement among authors as to what the nature of heat is, nor is there always consistency in the treatment by a given author. There are the contradictory statements that heat is a mode of motion, and that it is not motion,—that it is energy, and that it can be destroyed; that it is ether waves and that ether waves cannot properly be called heat.

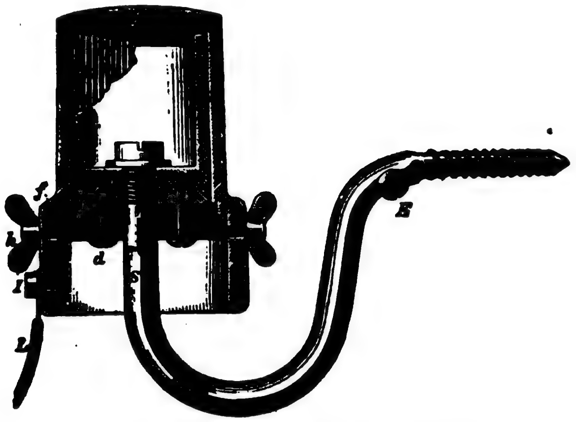
MULTIPLEX TELEPHONY.

The attempts which have in the past been made to multiplex telephone lines have mostly been based on the differential method of working. When, some time ago, Lieut. F. Jarvis Patten designed his system of multiplex telegraphy, however, he also recognized the applicability of the system to telephony, but his attention was so much occupied by the telegraph that the former was laid aside temporarily. Recently, however, he has taken up the telephone again, and has now succeeded in operating a good sextuplex, by which six telephone messages can be sent simultaneously over a single line with either grounded or metallic circuit. The further development of the system will be watched with great interest.

THOMSON ELECTRIC WELDING COMPANY.—The American Wheel Co., headquarters at Chicago, which has bought up all the principal wheel companies of the United States, has heretofore sold its wheels without tires, but will hereafter tire all wheels before sending them out, using the electric welding process. This will bring the Thomson Electric Welding Co. a revenue from royalties on at least 1,000,000 welds annually.

THE WEHR LIGHTNING ARRESTER.

The custom has prevailed almost universally hitherto of mounting lightning arresters in close proximity to the apparatus to be protected within buildings, thus allowing the lightning charge to pass into the building before it is turned aside to be discharged into the earth. It is evident, however, that increased safety may be attained if lightning arresters, even for ordinary apparatus, can be placed entirely without the building. When thus placed, however, it is evident that it must be so designed as to be protected against the influences of the weather and malicious interference. With the object of affording lightning protection to instruments while confining the path of the current to the outside of the building, Mr. G. Wehr, of Berlin, has designed a lightning arrester, known as the "Universal," which is illustrated in the accompanying engraving. The instrument is there shown as designed for the protection of but a single conductor, and consists of a bell-shaped hood *g*, of galvanized cast-iron, which is connected with the earth. The upper, interior part of this bell is provided



The Wehr Lightning Arrester.

with vertical ribs. The lightning arrester, *a*, is supported by the bent rod s, provided with a wood or steel screw. The arrester *a*, it will be noted, is cone-shaped, and made of brass, with small horizontal ribs. The cone is in metallic connection with the support s, which is connected to earth by means of the screw E. Both parts are insulated from the hood *g* by the ebonite plates *b* and *c*. Resting on the heel of the lower ebonite plate *c* is a soft rubber ring, *f*, which, being compressed by the hood, makes an air-tight joint between the hood and the arrester *a*. The presence of this rubber washer prevents the entrance of dust and metallic particles as well as dampness between the conductor and the earth connection. The thumb-screws *h* serve to fasten the hood *g* to the plate *c*, maintaining the cone *a* on the ebonite piece. In the arresters of this pattern, designed for 2, 3 and 4 conductors, the interior cone is divided vertically into as many parts as there are conductors to be protected. Each of these parts is connected with a short column provided with a screw to which the conductors to be protected are connected.

AN ELECTRIC RIVETING MACHINE.[1]

Electricity has already been applied in a variety of ways to the driving of tools and iron-working machinery, and its most recent application is to a riveter designed by M. Singre. This machine is based on the same principle as the coin presses now in general vogue, and in which the principle employed is to give a large mass a considerable energy which is suddenly deprived of that energy by the die coming in contact with the metal which receives the impression. The accompanying illustrations represent the new machine, Fig. 1 being a horizontal section of the electric motor, which has four poles, A being the ring, B the field magnet coils and C the pole pieces. Fig. 2 represents a vertical section.

As will be seen, the axis or shaft of the ring armature consists of a screw-threaded tube maintained in its position

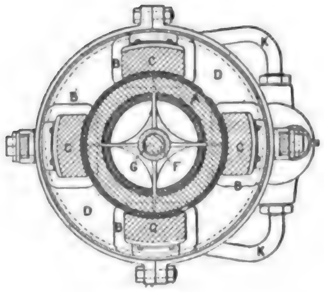


Fig. 1.—The Singre Electric Riveter.

at its upper end by the cap, H, and below by means of a collar. The commutator is shown at E. In the interior of the screw-threaded tube there is situated a very heavy screw, F, which does not rotate with the ring, being held in a fixed position by means of the guides shown in Fig. 3. The screw is terminated by a piston, J, which penetrates a reservoir of oil, J, from which lead two tubes, K K. These tubes end in a cylinder in which there moves a piston of large surface, L. The end of this piston carries the die, M, which forms the rivet-head, the opposite, abutting die, N, being placed at the lower end.

When the current is sent through the motor the latter at

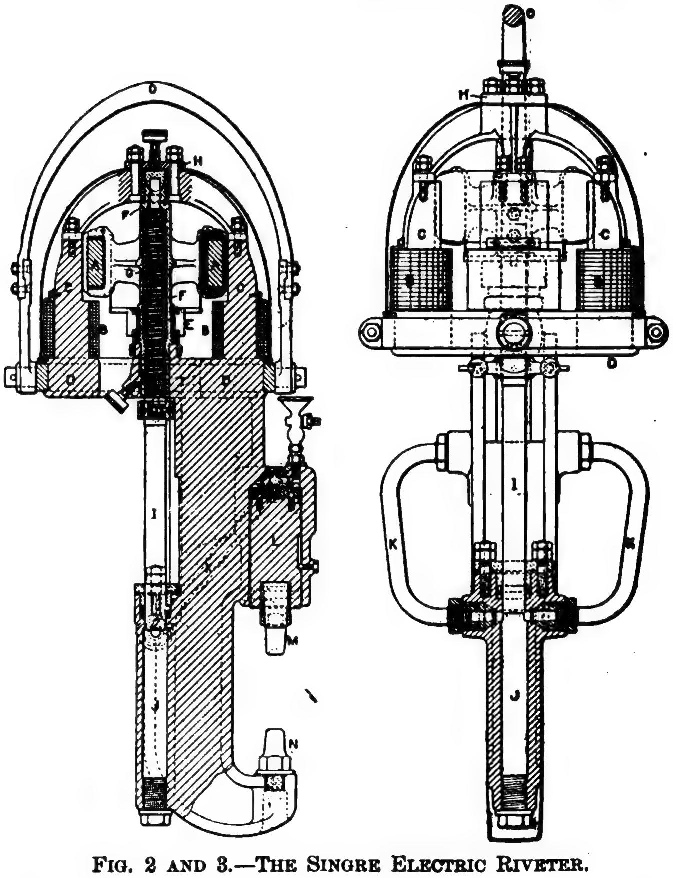

Fig. 2 and 3.—The Singre Electric Riveter.

once attains a very high speed which increases, owing to the fact that there is scarcely any resistance to overcome, and hence the piston, I, descends very freely at a considerable velocity; but at the moment the die, M, meets the rivet head it is suddenly stopped; but the ring, the core of which is of iron, and very heavy, has acquired considerable energy during the free descent of piston, I. On the other hand the combination of a screw and hydraulic press makes a powerful combination, which lends itself readily to the exertion of great power with a small initial force.

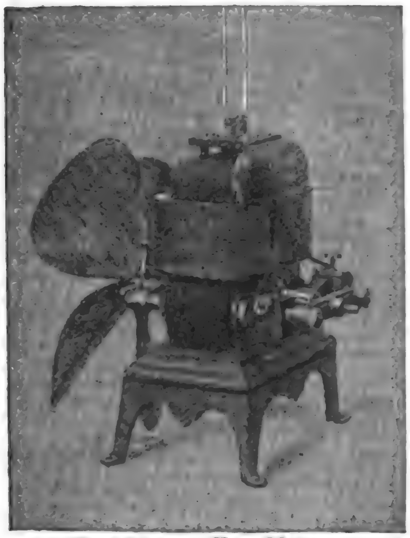
1. M. Deprez in *La Lumière Electrique*.

ELECTRIC FANS FOR HOT WEATHER.

THE recent hot weather has naturally directed the attention of the public to artificial methods of cooling, and it may safely be said that of such methods one of the most popular to-day is that of propelling small fans by electric motors. A few years ago, and even to-day, mechanical or clock-work fans were in general favor, but their size, and awkwardness of motion, as well as the feebleness of the breeze created by them, has prevented such a universal adoption of them, as now awaits the electric fan.

Some of the electric motor companies have considered the fan business as beneath their dignity, and they have therefore refrained from making "fly-power" motors. In this respect, they have, we think, made a mistake, even though the field is large enough to occupy their attention in other directions. In the aggregate the small motors represent a large sum of money and a large amount of power, and each is, or should be, an excellent advertisement for its builder. In a few years there will certainly be as many such motors as there are sewing machines, for example, and the number will be even greater when the opportunities for their use in driving fans, sewing machines, dental lathes, phonographs, graphophones and other minor appliances of comfort and civilization are appreciated.

Among those who have from the first exploited the small, as well as the large, motor field are the Elektron Manufacturing Company, of Brooklyn, whose fan motor we illustrate on this page. A large number of these have been



THE PERRET FAN MOTOR.

put in service all over the country, and in Brooklyn these Perret motors have literally become a "household word," so universally have they been introduced throughout that city of homes. The cut represents a Perret motor (type A. O. single speed) with a four-bladed fan on the armature shaft. The same fan fits the three speed motor, and the latter is used when change in strength of the breeze is desired. The motor may be screwed to a shelf in such a manner that the fan will clear its edge, but a better arrangement is that shown in the figure, where the motor is fixed on a neat japanned iron stand, which permits it to be set on any flat top table. A wire guard which is easily attached to the motor and which surrounds the fan, preventing accidental contact with the revolving blades, may be used if desired.

A suitable 2 volt primary cell, such as the Mason or other of that type, in connection with this apparatus will produce a gentle breeze, at a cost of about one cent per hour, and two cells will give a blast twice as strong, which is as much as would ever be required in an ordinary sized room. Current required is from 3 to 5 amperes. A similar result will be produced by one or two storage cells.

The operation is smooth and quiet and the motor is ornamental as well as useful, especially when nickel-plated. It deserves note that in these small motors, the same distinctive features of lamination of the field magnets are adhered to. The weight of the one-eighth horse-power motor here shown is only 13 lbs. It is run with a round eighth-inch belt on a $1\frac{1}{4}$ inch pulley, the speed depending, of course, upon the current supplied.

ELECTRO METALLURGY.

MESSRS. SIEMENS AND HALSKE, of Berlin, have recently patented a process for the electrical treatment of ores, of which the following are the principal points: The ore, first being pulverized, is put into a cylinder filled with a solution of sulphate of iron. The mixture is kept constantly in motion by means of moving pallets, and if there is need the bath is steam-heated. If the process is used for amalgamation, cylinders of copper, partly plunged in mercury, are placed in vessels and set in a rotatory motion. This movement assures a constant contact between them and the mineral, and the reduction takes place. In a more general case a solution of alkaline cyanide is added to the electrolyte, and an electric current is turned on. The metal is deposited on a cylinder of copper. After the operation the copper is recovered by ordinary methods. This process will be applicable in the treatment of the ores of copper, zinc, and precious metals.

MEASUREMENT OF ELECTRO-MAGNETIC RADIATION.

At a meeting of the Physical Society the results of an important research on the measurement of electro-magnetic radiation were experimentally shown by Mr. Vernon Boys. It will be remembered that Mr. Gregory some time since succeeded in measuring the expansion of a fine wire caused by the heating effect of the electrical oscillations set up within it; and, with the view of confirming this result, Mr. Boys has employed two distinct methods, the application of which has needed great ingenuity and manipulative skill. One of these methods, depending on the mechanical forces exerted between two adjacent wires in which oscillations were induced, appeared at first to succeed, owing to an extraneous effect; but after this had been carefully eliminated, no action could be detected, although the adjustments were delicate enough to indicate a force of less than a one hundred-millionth part of a grain.

JERRITT'S MILITARY FIELD SOUNDER.

This apparatus, which has been devised by Mr. Jerritt, of Plymouth, England, consists of a small instrument so arranged as to be capable of being used as a transmitter and receiver. By an ingenious arrangement, the lever of the sounder is employed both for sending and receiving messages, thus doing away with the ordinary apparatus for transmitting telegraph work, the current being put on and off by means of a small switch fixed to the base of the instrument. A telephonic arrangement can be adjusted for receiving purposes if required. The instrument, battery, sounding-box, and telescopic stand fold up and form a compact knapsack, and can be comfortably carried as such by any operator. The centre of the stand, it may be mentioned, can be used if necessary as a drum for winding a quantity of wire.

ELECTRO-MAGNETIC REPULSION.

Those who have not the means of showing the striking effects produced by Prof. Elihu Thomson, writes Mr. W. B. Craft, in *Nature*, may be glad to know a simple illustration of the same principle.

A top consists of a soft iron disc with a brass axis put through it. A small magnet is held over the edge whilst spinning; each elementary sector as it moves up to and away from the poles of the magnet has currents induced which are repelled by the magnet; as the rotation dies out, the currents at a certain point become too feeble to overcome the attraction of the soft iron by the magnet.

SAN FRANCISCO WIRE-TAPPERS CAUGHT.

After faithful watching and waiting for the last eighteen months the Detective Department of San Francisco caught recently two of a band of thieves who have robbed the pool-rooms of San Francisco of nearly \$100,000. The prisoners are a telegraph operator and a young man about town whose father left a considerable sum to his boy by will about two years ago. The men were captured in the Benson Building while in the act of receiving a message over a looped-wire. They had connected their wires with those leading to the pool-rooms.

INSURANCE OF ELECTRIC PLANTS.

NOTHING for a long time has created quite so much stir and excitement with the stock fire insurance companies and their local agents as the advent of the Electric Mutual Insurance Company to insure electric plants.

Ever since the first plant was established, these companies and agents have looked upon the risks as being very hazardous, and for the most part the companies have declined to insure them; not because there is any record to show by their having burned frequently that they were extra hazardous, but the same old "mysterious something" (and they knew not what) has made their judgment hide behind their fear. Of course, the agent has sought high and low for companies that would take the risks so that he might secure his 15 or 20 per cent. commission on the premiums. The hazard of the risk was nothing to him if he could "place" it at all; in fact, the supposed extra hazardousness has operated to his great advantage, because the greater the premiums the more commission he realized.

Several companies, being willing to gamble on anything at a high rate, have all along accepted the risks, but by reason of there being but few taken they have been enabled to secure very exorbitant rates. They have cried down the risks and raised their rates, but they haven't refused any of the business, except to get a higher rate. As a result they have made large profits. The rates have been made so high that few of the electric companies have felt able to carry more than a very small percentage of their value in insurance. As a consequence, when a small loss would occur it would result in nearly a total loss to the insurance companies under their policies. Then would go up the cry that not only were electric stations *very extra hazardous*, but the property was *very perishable*, and a small fire that wouldn't damage any other kind of machinery very much would *ruin* dynamos and other electric apparatus. So that early in the game they began to discriminate against dynamos, and to apply the "co-insurance clause" to their policies. The latter clause is one which compels the property owner to have full insurance or become a contributor to his own loss, in the proportion that his insurance is less than the value of his property.

The condition of things has been growing worse rather than better. In many parts of the country electric stations have been tariff-rated by the insurance boards at figures ranging from 2 to 4 per cent.—almost as high as planing mills and other similar risks. The result of this rating has been to debar all "board" companies from taking the risks at less rates even if they were willing to do so. Another result of the tariff and of the small number of responsible companies that would accept such risks has been the compelling of agents to secure policies in all sorts of shyster or irresponsible companies, because the high rates (presumed to have been made intelligently) have frightened the good companies to that degree that a sufficient number could not be found to carry the amount of insurance wanted. The agent's only recourse then was to get policies where he could and at such rates as he could. If the names of companies carrying electric station risks at the present time could be made public it would probably disclose the poorest lot of companies, as a class, on any risk in the market; and, if the rates could also be made public, it would indicate the highest rated risk as a class. Under such circumstances it is not strange that the electrical interests should welcome the advent of a company of their own, allied to no tariff organization and therefore free to act independently and intelligently, as well as being governed by a board of directors, all of whom are electrical men. But how changed and varied is the attitude of the several underwriters' boards! In some instances they get their heads together and say: "We will maintain our tariff rates on each station until we feel that the Electric Mutual Company is after it and then we will drop our rates sufficiently to hold the risk." In other cases they conceive the idea that the Mutual Company can only carry a small portion of the risk anyway, and that if they can, through board obligations, prevent stock companies from co-operating with the Mutual, it will be unable to control the rates on the whole risk, and thereby they can retain a part of it at their own high figures, besides having the guarantee of an improved risk through the inspection of the Mutual, without cost to themselves.

Several of the largest stock companies doing business in the country realized in the beginning the advantage of taking surplus insurance from the Electric Mutual Company and entered into an arrangement with that company whereby they were to accept all risks offered and at rates named by the Mutual, and they were to pay their share of the expense of examinations. No sooner, however, had they secured a few risks in this way than the local agent (who had lost the risk and thereby his big commission) began to pour his complaints into his companies that his inalienable (?) rights were being violated by "Board" companies—that he was being deprived of good business that he could hold at high rates (and big commission) if the Board Companies would all stand by him and forsake the Mutual. The complaint was taken up by the "special agent" (the drummer of insurance), who is always eager to enhance the interests of his own company by catering to the feelings of his agent and crying out against the actions of other companies. The local board as a body made its solemn protest, and the cry passed all along the line that "rates were being cut by Board Companies." It came to the great "head centres"—the large organizations composed of the companies, namely:—the "Western Union," the "Middle States Department" and the "South Eastern Tariff Association." Their inquiry went forth, in solemn but determined order, to the companies who were quoted as co-operating with this Mutual—who were aiding and abetting it in its *nefarious* purpose of reducing and equalizing rates. The inquiry was somewhat after the following style:—"You are quoted as having issued your policy on the Electric Light Station, at ...., at 1%, the risk having recently been rated at 3½% by this Association. Will you please advise us if the charge is true; also whether it is your purpose to sustain the rates of this Association, or not?" At the same time the busy and ever-present special agent would put in his work again, with the local agent, by pointing out in his most vivid style the iniquity of the company that would issue a policy through the agency of a competing Mutual Company, in the territory and over the head of their local agent. He would supplement this portrayal of wickedness by advising the agent to give his business only to those companies that would protect him and his rates. And so the offending company would receive its notice from that quarter, either to the effect that its agency was no longer wanted, or by a suspension of business which was tantamount to a notice to the same effect. Nor did it stop there. The special agent and the injured local agent had so poisoned the minds of other local agents that the wicked company, if it sought a representative at another office, found the door locked against it. It seems to be an unfortunate condition of the business that the great insurance company, with its millions of dollars, is forced to make choice between two positions, either abandon its judgment and opportunities as to a certain class of desirable business at fair rates—the electric stations —or suffer the loss of its other good business. Furthermore, it seems that the "special agent" whose Company don't insure electric stations anyway, is the loudest in his howling. He doesn't want the risk and he isn't willing his associate shall have it, because by inveighing against him he can ingratiate himself and his own Company deeper into the heart of the local agent and secure the accompanying favors. It is the same old story of local board and local agent control. It has built up the system of Factory Mutuals in New England which are insuring over $500,000,000 on the best manufactories in the country; and they are doing it at so small a cost that a number of the large stock companies, feeling sore over their past loss of this immense amount of insurance and their continued losses, have recently formed a pool or syndicate to work independently of local boards and agents (doing the self same thing that is complained of in the electrical case), and are offering to take these risks at one-quarter of one per cent. per annum. It costs the manufacturers less to insure with the Mutuals and they will probably stay there.

A number of the Factory Mutuals have insured electric plants for several years and have only met with one loss. They now come forward, it is stated, and offer their co-operation with the Electric Mutual.

After the local agents, with their big rates and big commissions have driven the electric station insurance into Mutuals, it will dawn upon the stock companies that such risks belong in the "preferred class" and their efforts to regain them will probably be equalled only by their action in driving them away now.

In the midst of the tempest that is raging in the insurance teapot it is refreshing to see such sensible words as the following from the *Insurance Times*, of New York, in a recent issue:—"In the West there is the sign of a big row over the insurance of electric lighting plants by the new Electric Mutual Company, of Boston. A plaintive cry is heard all the way from Colorado that local agents have lost a large line on a station in that State because the insurance has been handed over to the Boston concern. One company in this city has a four-page letter from a Colorado special on this topic, and he wants to know what the companies in New York are going to do to protect their Colorado agents. The probable answer is 'nothing,' because in a large majority of such cases the stock of the electric light company is owned in the East, and the owners take out their insurance here for other reasons than to deprive local agents of it. There are a score of corporations with headquarters in Boston, New York and Philadelphia whose properties in the South and West are insured by companies in the cities named for local reasons which to the owners are quite as potential as the claims of local agents to the business."

Some large whiskey risks in Cincinnati were recently transferred from the agents of that place to agents in Peoria, Ill., presumably for reasons satisfactory to the owners of the property. The Cincinnati agents, who seem to think they own the whiskey as well as that part of the earth on which the city stands and considerable country adjacent thereto, got together and, after "whereasing" at great length, they resolved as follows:—

"That we, the undersigned agents, representing the companies set opposite our names, hereby agree that if any companies represented in Cincinnati by authorized agents shall write policies of insurance upon any risk in the territory belonging to said agent

or agents, or having written such policies shall refuse to cancel the same within ten days from date, we, each and every one of us, agree that we shall immediately cease to do any business for such company, and will hold the agency supplies subject to the company's orders; and we, each and every one of us, further agree that we will not accept the agency of any company which desires to change its local agents on account of the enforcement of this compact agreement."

Precisely the same disposition is manifested in relation to the insurance of electric plants in stock companies through any agent who doesn't happen to live next door to the plant. While such arbitrariness exists it is not much wonder that legislatures enact laws adverse to the interests of insurance companies.

ELECTRO-MAGNETIC RADIATION.[1]

In order to discover whether actions are propagated in time or instantaneously, we may employ the principle of interference to measure the wave-length of a periodic disturbance, and determine whether it is finite or no. This is the principle employed by Hertz to prove experimentally Maxwell's theory as to the rate of propagation of electro-magnetic waves. In order to confine the experiments within reasonable limits we require short waves, of a few metres' length at most. As the highest audible note gives waves of five or six miles long, and our eyes are sensitive only to unmanageably short waves, it is necessary to generate and observe waves whose frequency is intermediate between them, of some hundred million vibrations per second or so. For this purpose we may use a pair of conducting surfaces connected by a shorter or longer wire, in which is interposed a spark-gap of some few millimetres' length. When the conductors are charged by a coil or electrical machine to a sufficiently high difference of potential for a spark to be formed between them, they discharge in a series of oscillations, whose period for systems of similar shape is inversely proportional to the linear dimensions of the system so long as the surrounding medium is unaltered. When the surrounding non-conducting medium changes, the period depends on the electric and magnetic specific inductive capacities of this medium. Two such systems were shown: a large one, whose frequency was about 60 millions per second; and a small one, whose frequency was about 500 millions per second. The large one consisted of two flat plates, about 30 cm. square and 60 cm. apart, and arranged in the same way as is described by Prof. Hertz in *Wiedemann's Annalen*, April, 1888. The smaller vibrating system consisted of two short brass cylinders terminating in gilt brass balls of the same size, and arranged in the same way as the smaller system described by Prof. Hertz in *Wiedemann's Annalen*, March, 1889. This latter system was placed in the focal line of a cylindrical parabolic mirror of thin zinc plate, such as that described by Prof. Hertz in this paper.

These generators of electro-magnetic oscillations may be called electric oscillators, as the electric charge oscillates from end to end. A circle of wire, or a coil in which an alternating current ran, or, if such a thing were attainable, a magnet alternating in polarity, might be called a magnetic oscillator. A ring magnet with a closed magnetic circuit is essentially an electric oscillator, while a ring of ring magnets would be essentially a magnetic oscillator again. The elementary theory of a magnetic oscillator can be derived from that of an electric oscillator by simply interchanging electric and magnetic force. Electricity and magnetism would be essentially interchangeable if such a thing existed as magnetic conduction. The only magnetic currents we know are magnetic displacement currents and convection currents, such as are used in unipolar and some other dynamos. It is in this difference that we must look for the difference between electricity and magnetism.

In order to observe the existence of these electro-magnetic oscillations we can employ the principle of resonance to generate oscillations in a system whose free period of oscillation is the same. A magnetic receiver may be employed, consisting of a single incomplete circle of wire broken by a very minute spark-gap, across which a spark leaps when the oscillations in the wire become sufficiently intense. In order that a large audience may observe the occurrence of sparks, the terminals of a galvanometer circuit were connected, one with one side of the spark-gap, and the other with a fine point which could be approached very close to the other side of the spark-gap. It was observed that, when a spark occurred in the gap, a spark could also be arranged to occur into the galvanometer circuit, and, with a delicate long-coil galvanometer (that used had 40,000 ohms resistance), a very marked deflection can be produced whenever a spark occurs. This arrangement we have only succeeded in working comparatively close to the generator, because the delicacy required in adjusting the two spark-gaps is so great. It can, however, be employed to show that the sparks produced in this magnetic resonant circuit are due to resonance by removing this receiver from the generator to such a distance that sparks only just occur, and then substituting for the single circuit a double circuit, which, except for resonance, should have a greater action than the single one, but which stops the sparking altogether. An electric receiver was also used, which was identical with the generator, and had a corresponding, only much smaller, spark-gap between the two plates. When the plates are connected with the terminals of the galvanometer, upon the occurrence of each spark the galvanometer is deflected. It is not so easy to obtain sparks when the plates are connected with the galvanometer as when they are insulated, and it is this that has limited the use of this method of observation. By making the first metre or so of the wires to the galvanometer of extremely fine wire, so as to reduce their capacity, we have found that the difficulty of getting sparks is less than with thick wires. We have not observed any effect due to the thickness of the wires after a short distance from the receiver.

In the case of the small oscillator, a receiver exactly like the one described by Prof. Hertz in his second paper, already quoted, was placed in the focal line of a cylindrical parabolic mirror, and its receiving wires were connected with the wires leading to the galvanometer by some very fine brass wire. With the large-sized generator and receiver, which were placed about three metres apart, it was shown that the sparking was stopped by placing a thin zinc sheet so as to reflect the radiations from a point close behind the receiver. By means of a long india-rubber tube hung from the ceiling, it was shown how, when waves are propagated to a point whence they are reflected, the direct and reflected waves interfering produce a system of loops and nodes, with a node at the reflecting point. It was explained that these nodes, though places of zero displacement, were places of maximum rotation, and that the axis of rotation was at right angles to the direction of displacement. It was explained that an analogous state of affairs existed in the electro-magnetic vibrations. If the electric force be taken as analogous to the displacement of the rope, the magnetic may be taken as analogous to its rotation, and the two are at right angles to one another. In the ether the electric node is a magnetic loop, and *vice versa*. Though the two are separated in loops and nodes, they exist simultaneously in a simple wave propagation, just as in a rope when propagating waves in one direction the crest of maximum displacement is also that of maximum rotation. It was explained that by placing the reflector at a quarter of a wave-length from the receiver this would be at an electric loop, and have its sparking increased. It may thus be shown that there are a series of loops and nodes produced by reflection of these electro-magnetic forces, like those produced in any other case of reflected wave-propagation. This was Hertz's fundamental experiment, by which he proved that electro-magnetic actions are propagated in time, and by some approximate calculations he verified Maxwell's theory that the rate of propagation is the same as that of light. It follows that the luminiferous ether is experimentally shown to be the medium to which electric and magnetic actions are due, and that the electro-magnetic waves we have been studying are really only very long light waves.

A rather interesting deduction from Maxwell's theory is that light incident on any body that absorbs or reflects it should press upon it and tend to move it away from the source of light. Illustrating this, an experiment was shown with an alternating current passing through an electro-magnet, in front of which a good conducting plate of silver was suspended. When the alternating current was turned on the silver was repelled. It was explained that as the silver could only be affected by what was going on in its own neighborhood, and that if sufficiently powerful radiations from a distant source were falling on the silver, it would be acted on by alternating magnetic forces, this experiment was in effect an experiment on the repulsion of light, which was too small to have been yet observed, even in the case of concentrated sunshine. These slow vibrations are not stopped by a sheet of zinc, though much reduced by a magnetic sheet like tin-plate, though the rapid ones are quite stopped by ether—thus showing that wave-propagation in a conductor is of the nature of a diffusion.

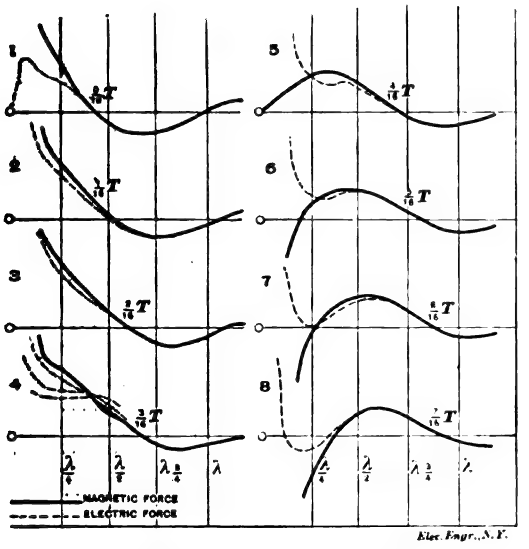
In all cases of diffusion where we consider the limits of the problem, terms involving the momentum of the parts of the body must be introduced. It appears from elementary theories of diffusion as if it were propagated instantaneously, but no action can be propagated from molecule to molecule, in air, for instance, faster than the molecules move, *i. e.*, at a rate comparable with that of sound. In electro-magnetic theory corresponding terms come in by introducing displacement currents in conductors, and it seems impossible but that some such terms should be introduced, as otherwise electro-magnetic action would be propagated instantaneously in conductors. The propagation of light through electrolytes, and the too great transparency of gold leaf, point in the same direction.

The constitution of these waves was then considered, and it was explained that if magnetic forces are analogous to the rotation of the elements of a wave, then an ordinary solid cannot be analogous to the ether because the latter may have a constant magnetic force existing in it for any length of time, while an elastic solid cannot have continuous rotation of its elements in one direction existing within it. The most satisfactory model, with properties quite analogous to those of the ether, is one consisting of wheels geared with elastic bands. The wheels can rotate con-

1. Friday Evening Lecture delivered at the Royal Institution, on March 21, by Prof. G. F. Fitzgerald, F. R. S.

tinuously in one direction, and their rotation is the analogue of magnetic force. The elastic bands are stretched by a difference of rotation of the wheels, and introduce stresses quite analogous to electric forces. By making the elastic bands of lines of governor balls, the whole model may have only kinetic energy, and so represent a fundamental theory. Such a model can represent media differing in electric and magnetic inductive capacity. If the elasticity of the bands be less in one region than another, such a region represents a body of higher electric inductive capacity, and waves would be propagated more slowly in it. A region in which the masses of the wheels was large would be one of high magnetic inductive capacity. A region where the bands slipped would be a conducting region. Such a model, unlike most others proposed, illustrates both electric and magnetic forces and their inter-relations, and consequently light propagation.

In the neighborhood of an electric generator the general distribution of the electric and magnetic forces is easily seen. The electric lines of force must lie in planes passing through the axis of the generator, while the lines of magnetic force lie in circles round this axis and perpendicular to the lines of electric force. It is thus evident that the wave is, at least originally, polarized. To show this, the small-sized oscillators with parabolic mirrors were used, and a light square frame, on which wires parallel to one direction were strung, was interposed between the mirrors. It was shown that such a system of wires was opaque to the radiation when the wires were parallel to the electric force, but was quite transparent when the frame was turned so that the wires were parallel to the magnetic force. It behaved just like a tourmaline to polarized light. It is of great interest to verify experimentally Maxwell's theory that the plane of polarization of light is the plane of the magnetic force. This has been done by Mr. Trouton, who has shown that these radiations are not reflected at the polarizing angle by the surface of a non-conductor, when the plane of the magnetic force in the incident vibration is perpendicular to the plane of incidence, but the radiations are reflected at all angles of



Electro-Magnetic Radiation.

incidence when the plane of the magnetic force coincides with the plane of incidence. Thus the long-standing dispute as to the direction of vibration of light in a polarized ray has been at last experimentally determined. The electric and magnetic forces are not simultaneous near the oscillator. The electric force is greatest when the electrification is greatest, and the magnetic force when the current is greatest, which occurs when the electrification is zero; thus the two, when near the oscillator, differ in phase by a quarter of a period. In the waves, as existing far from the oscillator, they are always in the same phase. It is interesting to see how one gains on the other. It may be worth observing again that though what follows deals with electric oscillators, the theory of magnetic oscillators is just the same, only that the distribution of magnetic and electric forces must be interchanged. Diagrams drawn from Hertz's figures published in *Wiedemann's Annalen* for January, 1889, and in *Nature*, vol. xxxix, p. 451, and in the *Philosophical Magazine* for March, 1890, were thrown on the screen in succession, and it was pointed out how the electric wave, which might be likened to a diverging whirl ring, was generated, not at the oscillator, but at a point about a quarter of a wave-length on each side of the oscillator, while it was explained that the magnetic force wave starts from the oscillator. It thus appears how one gains the quarter-period on the other. The outflow of the waves was exhibited by causing the images to succeed one another rapidly by means of a zoëtrope, in which all the light is used and the succession of images formed by having a separate lens for each picture and rotating the beam of light so as to illuminate the pictures in rapid succession.

As the direction of flow of energy in an electro-magnetic field depends on the directions of electric and magnetic force, being reversed when either of these is reversed, it follows that in the neighborhood of the oscillator the energy of the field alternates between the electric and magnetic forms, and that it is only the energy beyond about a quarter of the wave-length from the oscillator which is wholly radiated away during each vibration. It follows that in ordinary electro-magnetic alternating currents at from 100 to 200 alternations per second, it is only the energy which is some 3,000 miles away which is lost. If an electro-magnetic wave, having magnetic force comparable to that near an ordinary electro-magnet, were producible, the power of the radiation would be stupendous. If we consider the possible radiating power of an atom by calculating it upon the hypothesis that the atomic charge oscillates across the diameter of the atom, we find that it may be millions of millions of times as great as Prof. Wiedemann has found to be the radiating power of a sodium atom in a Bunsen burner, so that, if there is reason to think that any greater oscillation might disintegrate the atom, it is evident that we are still a long way from doing so. It is to be observed that ordinary light-waves are very much longer than the period of the vibration above referred to. Dr. Lodge has pointed out that quite large oscillators in comparison to molecules—namely, about the size of the rods and cones in the retina—are of the size to resound to light-waves of the length we see, and so might be used to generate such waves. This seems to show that the electro-magnetic structure of an atom must be more complicated than a small sphere or other simple shape with an oscillating charge on it, for the period of vibration of a small system can be made long by making the system complex, *e. g.*, a small Leyden jar of large capacity with a long wire wound many times round connecting its coats, could easily be constructed to produce electro-magnetic waves whose length would bear the same proportion to the size of the jar as ordinary light-waves do to an atom. The rate at which the energy of a Hertzian vibrator is transferred to the ether is so great that we would expect an atom to possess the great radiating power it has. This shows, on the other hand, how completely the vibrations of an atom must be forced by the vibrations of the ether in its neighborhood, so that atoms, being close compared with a wave-length, are, in any given small space, probably in similar phases of vibration. It is interesting to consider this in connection with the action of molecules in collision as to how far the forces between molecules after collision is the same as before. In the same connection the existence of intra-atomic electro-magnetic oscillations is interesting in the theories of anomalous dispersion. An electro-magnetic model of a prism with anomalous dispersion might be constructed out of pitch, through which conductors, each with the same rate of electro-magnetic oscillations, were dispersed. In theories of dispersion a dissipation of energy is assumed, and it may be the radiation of the induced electro-magnetic vibrations. These can evidently never be greater than the incident electro-magnetic vibration, on account of this radiation of their own energy. In some theories a vibration of something much less than the whole molecule is assumed, and the possibility of intra-atomic electro-magnetic oscillations would account for this. Some such assumption seems also required, in order to explain such secondary, if not tertiary, actions as the Hall effect and the rotation of the plane of polarization of light, which are, apparently at least, secondary actions due to a reaction of the matter set in motion by the radiation on this radiation.

Some further diagrams were exhibited, plotted from Hertz's theory by Mr. Trouton, to whom much of the matter in this paper is due. They are here reproduced, and show eight simultaneous positions of the electric and magnetic waves during a semi-oscillation of an electric oscillator. The dotted line shows the electric force at various points, and the continuous line the magnetic force. In the first diagram the magnetic force is at its maximum near the origin, while the electric force there is zero. In the second the magnetic energy near the origin has partly turned into electric energy, and consequently electric force begins. The succeeding figures show how the magnetic force decreases near the origin, while the electric force grows, and the waves already thrown off spread away. The change of magnetic force between Figs. 4 and 5 is so rapid, that a few dashed lines, showing interpolated positions, are introduced to show how it proceeds. It will be observed how a hollow comes in the line showing electric force, which gradually increases, and, crossing the line of zero force at about a quarter of a wave-length from the origin, is the source of the electric wave, which, starting with this odds, picks up and remains thenceforward coincident with the magnetic wave. From this origin of electric waves they spread out along with the magnetic waves and in towards the origin, to be reproduced again from this point on the next vibration. These electric and magnetic forces here shown as coincident are, of course, in space in directions at right angles to one another, as already explained. The corresponding diagrams for a magnetic oscillator are got by interchanging the electric and magnetic forces.

A further experiment was shown to illustrate how waves of

transverse vibration can be propagated along a straight hollow vortex in water. It was stated that what seemed a possible theory of ether and matter was that space was full of such infinite vortices in every direction, and that among them closed vortex rings represented matter threading its way through the ether. This hypothesis explains the differences in Nature as differences of motion. If it be true, ether, matter, gold, air, wood, brains, are but different motions. Where alone we can know what motion in itself is—that is, in our own brains—we *know* nothing but thought. Can we resist the conclusion that all motion is thought? Not that contradiction in terms, unconscious thought, but that all living thought; Nature is the language of One in whom we live, and move, and have our being.

ON A BALLISTIC ELECTROMETER.[1]

BY M. GOUY.

THE quadrant electrometer can be used ballistically if the usual damping arrangement is removed, and the needle suspended by a conducting wire. The impulse given to the needle by a moment M acting for a very short time is equal to $\int M\,dt$; and as M may be made proportional either to V or V^2, where V is the potential difference between the quadrants, it thus becomes possible to measure $\int V\,dt$ and $\int V^2\,dt$. Thus if the needle is charged to a high constant potential, the magnitude of the first swing is proportional to $\int V\,dt$; and if the quadrants are connected with the two terminals of a resistance R through which a quantity Q of electricity passes in a very short time it is easy to see that whatever the self-induction of the resistance R,

$$\int V\,dt = RQ.$$

This formula has been practically tested with a Mascart electrometer, whose needle was suspended with a platinum wire 0.02 mm. in diameter, and charged to a potential of 300 volts. With this instrument a discharge of one microcoulomb through a megohm gave a deflection of 130 mm. on a scale two metres off, the period of the needle oscillations being 11.6 seconds. It is necessary that the capacity of the condenser used for the discharge should not be too high, or the time taken for the discharge will prevent the electrometer acting ballistically. The action is, however, satisfactory if the product of the capacity in microfarads and the resistance in megohms does not exceed $\frac{1}{5}$th.

In this way large resistance may be conveniently measured, and, as very small quantities of electricity are used, the method is especially suitable for liquid resistances, where difficulties usually arise from polarization. If, instead of Q being known, R is known, the method is one for measuring electrical quantity; and the electrometer thus does the duty of a ballistic galvanometer. The sensibility may, however, be made very great by giving a high value to R. By a suitable modification of the method, condensers of widely different capacities may be compared, and by connecting the needle to one pair of quadrants the electrometer may be used as a ballistic electro-dynamometer.

THE OPTICS OF THE LIGHTNING FLASH.[2]

BY ERIC STUART BRUCE.

IN Mr. Shelford Bidwell's recent lecture on "Lightning" at the London Institution, I notice the author says that the lightning flash of artists has no existence in nature, and that it is an artistic fiction or symbol. May I venture to refer to a paper which I had the honor of reading before the Royal Meteorological Society (published in the current Quarterly Journal of the Society) only a few days after the delivery of Mr. Shelford Bidwell's lecture? In this paper I endeavored to show how the "zigzag" flash so often seen by observers, and frequently depicted by artists, may have its counterpart in nature, quite consistently with the evidence of the photographs of lightning flashes collected by the Royal Meteorological Society.

I suggested that such an appearance is not the flash itself, but the optically projected image of the flash formed on clouds, not of a smooth surface, but of the rocky cumulus type. The image of the flash takes the angles of the uneven surface and becomes zigzagged. I showed how this might be by casting the photograph of a lightning flash—the "streaming" flash—by means of the optical lantern, on model cumulus clouds, made of cotton wool. The "streaming" flash became distorted, and in fact zigzagged, so that it could not have been recognized as the type mentioned.

"Projection" lightning flashes surely must happen in nature, and might be accounted for in more ways than one. I will mention now one simple way which I illustrated by experiment at the meeting referred to. It is fairly well recognized that sheet lightning is the reflection of a flash on a cloud, for example; but if there happens to be the presence of a cloud with a small opening in it somewhere between the actual flash and the distant surface of clouds, then, instead of "sheet" lightning appearing on the latter, there will be "projection" lightning—that is, the image of the flash, whose shape will depend upon the shape of the cloud on which it is cast.

In speaking of zigzag representations of lightning flashes, it is important to make some distinction between the artistic zigzag and a common pictorial type such as is seen on the covers of electrical books, in dissolving views, in scenic effects, and even in street advertisements. It is hardly fair to saddle the artists with the latter class. A good specimen of an artistic zigzag flash, and one which shows an observance of nature, can be seen in Wilson's famous picture of "Celadon and Amelia."

It certainly seems at first sight strange that the "projection" flash should not be included in the photographs of lightning flashes. Its non-appearance may be due (1) to the photographic plates not being sufficiently sensitive to register a flash of diminished brilliancy, for the projected image of any source of light has not the same intensity as the source itself. (2) The "projection" flash being of rarer occurrence, the number of photographs yet taken may not have included it. If the type is rarer, it may be objected that it is not likely that artists would generally depict a rare type in preference to the more common one; but the less dazzling nature of the "projection" would be sufficient to account for its adoption, rendering the form of the flash more distinct to the average eye. To take an illustration, if an electric arc light is suddenly flashed before our eyes, we fail to distinguish the form of the white-hot carbon points, but if its image were flashed upon a screen, their form would be distinctly visible.

It is worthy of note that some painters have chosen to represent other types than what I have termed the "projection" flash. See Turner's "Stonehenge," where "streaming" lightning is pictured.

POWER REQUIRED TO OPERATE CERTAIN MACHINE TOOLS.

Mr. R. E. Dunston, the president of the Connecticut Motor Co., has recently worked out the following valuable data relative to the amount of power required to operate certain machine tools, as enumerated below:

Shop shafting, $2\frac{3}{16} \times 180$ ft., at 160 revolutions, carrying 26 pulleys, varying in diam. from 6" to 36", and running 20 idle machine belts........	1.32 h. p.
Lodge-Davis upright back-geared drill-press, having table 28" swing, drilling ¾" hole in cast iron with feed of 1" per min..........................	.78 h. p.
Morse twist drill grinder, No. 2, carrying 2-6" wheels at 3,200 revolutions..........................	.29 h. p.
Pease planing machine, $30'' \times 36'' \times 6$ ft. table, planing cast iron, cut ¼" deep, planing 6 sq. in. per min., at 9 reversals.	1.06 h. p.
Shafting machine, 22" stroke, cutting steel die, 6" stroke and ⅛" deep, shaping at rate of 1.7 sq. in. per min..........................	.37 h. p.
Engine lathe, 17" swing, turning steel shaft 2⅜" diam., cut $\frac{3}{16}$" deep and feeding 7.92" per min	.43 h. p.
Engine lathe, 21" swing, boring cast-iron pole 5" diam., cut $\frac{3}{16}$" deep, feeding 3" per min................	.23 h. p.
Sturtevant Monogram blower, No. 2, at 1,800 revs., no piping	.80 h. p.
Heavy planer, $28'' \times 28''$, 14 feet bed, stroke 8", cutting steel, making 22 reversals per min..........	3.20 h. p.

"AN ELECTRIC SUCCESS."

About eight years ago last January there appeared from New York a handsomely gotten up though small paper called THE ELECTRICIAN. It was monthly, and the subscription was but fifty cents a year. It seemed to prosper, and in perhaps a year it was enlarged and the tariff doubled. Still it increased in size and circulation until later on as THE ELECTRICIAN AND ELECTRICAL ENGINEER, at a trebled price, it became famous among journals of its kind. Recently, as THE ELECTRICAL ENGINEER, it appeared as a weekly publication of from fifty to sixty pages, and is now probably the leading technical electrical periodical of America.—*San Francisco Newsdealer.*

THE RIES ELECTRIC TRACTION AND BRAKE CO.

The Ries Electric Traction and Brake Company has recently been incorporated, with a capital stock of $2,000,000, divided into 20,000 shares of $100 each.

The company has purchased the United States patents granted to Elias E. Ries for methods of, and apparatus for, increasing traction electrically, and for electric braking, and will carry on a general manufacturing business in connection with the introduction of its electric traction increasing and brake appliances. The incorporators and officers of the company are John M. Denison, president; John B. McDonald, vice-president; James Sloan, Jr., treasurer; Elias E. Ries, consulting electrician; Charles Selden, director; John W. Snyder, director; and Charles H. Jones, Jr. The principal offices of the company are in the Chamber of Commerce building, Baltimore. Satisfactory experimental trials of the apparatus have already been made, and further tests on a more extensive scale are now under way at Mount Clare.

ON THE ELECTRO-DEPOSITION OF PLATINUM.[1]

BY WM. H. WAHL.

Thus far, of all the methods that have been proposed for electro-plating with platinum, three only appear to have sufficient merit to deserve special notice; these are:

1. Roseleur-Lanaux method, based on the electrolysis of a solution of the double phosphate of sodium and platinum.

2. The process of the Bright Platinum Plating Company (of London), a modification of that of Roseleur, involving the introduction into the bath of certain substances, such as sodium chloride and borax, to ensure a bright deposit of the metal; and

3. Boettger's method, founded on the electrolysis of a solution of the double chloride of ammonium and platinum in sodium citrate.

Each of these baths will yield satisfactory results for a time; but the peculiar difficulties met with in the practice of platinum-plating render it impossible to maintain the chemical integrity of these electrolytes, and, in consequence thereof, they soon become inefficient or inoperative by reason of contamination with the secondary products formed therein.

The first difficulty encountered is that of obtaining a bright, reguline and adherent deposit of the metal, in which form only it will answer the demands of practice. Another and no less serious difficulty arises from the insolubility of plates or sheets of this metal as anodes, when solutions containing platinum salts are submitted to electrolysis.

It results from this want of solubility of the anode that the metallic strength of the electrolyte employed is continuously being weakened while the deposition of the metal is going on, and the conductivity of the bath is being continually modified thereby. The character of the deposited metal also is injuriously influenced by these constant alterations of condition in the bath; and, as the rate of deposition becomes slower and slower by reason of the gradual impoverishment of the metallic strength of the solution, it will be necessary to restore it by fresh additions of metallic salt.

It occurred to me that it might be practicable to overcome the principal difficulty here set forth. Knowing the influence of extent of surface in promoting the solubility of substances, it appeared to me at least probable that if the platinum were exhibited at the anode in the form of platinum-black, or sponge, exposing thus an enormously greater number of points of attack to the electro-negative element or acid radical there set free, the result might be the solution of the platinum, and the problem of maintaining the metallic strength of the electrolyte would thus be solved. The correctness of this conjecture was verified by experiment. For this purpose a plate of porous battery carbon, previously treated with boiling hydrochloric and nitric acids, was saturated repeatedly with a solution of platinic chloride and dried. It was then introduced into a graphite crucible, finely divided carbon was packed about it, and the crucible and contents heated for about half an hour to bright redness. The carbon plate then contained within its pores platinum in a state of eminently fine division. Treatment with water, and with hydrochloric acid at boiling temperature, failed to leach out any platinum salt, showing that the previous treatment had sufficed to reduce all the platinum salt to the metallic state. The carbon plate was then suspended as the anode in moderately diluted hydrochloric acid, a platinum plate serving as the cathode. The acid bath was gently heated and a current of moderate strength was allowed to flow through it. There was a liberal evolution of hydrogen from the cathode, but little perceptible evolution from the anode. The acid solution gradually became colored from the formation of platinic chloride, and after some time the bright surface of the cathode began to blacken and ultimately became covered with a thick coating of platinum black. It was thus demonstrated that an anode of platinum in a fine state of division is readily soluble in an electrolyte which yields chlorine at the anode when the same is electrolyzed. This observation, so far as I am aware, is new. It proved, however, to have no practical value, since the solution of the anode demanded the presence of a large proportion of free acid in the plating-bath and the use of currents of such strength as to produce invariably the deposition on the surfaces to be plated, of black and non-adherent metal. Furthermore, it was found as was to have been anticipated, that the physicial condition of the anode exerted no influence whatever in the electrolysis of baths formed of the oxy-salts of platinum, from which the best results in electro-plating are obtained—since, in electrolyzing such compounds, the acid radical separated upon the surface of the platinum black failed to exert any perceptible solvent action.

It was therefore necessary to devise some other plan for overcoming the difficulties herein described, and, after making a number of fruitless experiments, I was so fortunate as to find a plan which appears to offer a solution of the troublesome problem of electro-plating with the group of metals, whose anodes are insoluble, in a more satisfactory manner than any other that has hitherto been suggested.

The plan here referred to consists in employing platinum hydroxide for the purpose of maintaining the metallic strength of the plating-bath. For this purpose, the hydroxide, which is readily soluble in alkalies and in many of the acids, may be introduced into the plating-bath from time to time and dissolved therein by stirring, or it may be permitted to remain in the bath in excess, the undissolved portion remaining at the bottom of the containing vessel, or it may be suspended in a canvas-bag adjacent to or surrounding the anode of carbon, according as the nature of the electrolyte may indicate one or the other method to be the preferable one. As the solutions which yield the best results in plating are those of the oxygen salts, I have found it advantageous also to prepare these directly from the hydroxide. This method, I have found, is capable of yielding a number of electrolytic baths of platinum that will maintain their metallic strength approximately unimpaired during the electrolysis, and without the objectionable features of introducing into them substances that will cause them to deteriorate by the accumulation therein of injurious secondary products of decomposition, as is the case where such baths are maintained by additions of platinic chloride or alkaline chloro-platinates, as has hitherto been the invariable practice.

I append directions for the preparation of several electrolytic baths and indicate what I have found to be the most favorable conditions for working them.

Directions for Preparing the Electro-Plating Baths.—For the alkaline platinate bath, the following directions may suffice:

Platinic hydrate.	2 oz.
Caustic potassa (or soda)...	8 oz.
Distilled water...............	1 gallon.

Dissolve one-half of the caustic potassa in a quart of distilled water; add to this the platinic hydrate in small quantity at a time, facilitating solution by stirring with a glass rod. When solution is effected, stir in the other half of alkali dissolved in a quart of water to form one gallon of solution. To hasten solution, the caustic alkali may be gently heated, but this is not necessary, as the platinic hydrate dissolves very freely. This solution should be worked with a current of about two volts and will yield metal of an almost silvery whiteness upon polished surfaces of copper and brass, and quite freely. There should be slight, if any, perceptible evolution of hydrogen at the cathode, but a liberal evolution of oxygen at the anode. I have observed that the addition of a small proportion of acetic acid to this bath improves its operation where a heavy deposit is desired. The anode may be of platinum or carbon, and, owing to the readiness with which the metal is deposited, an excess of anode surface is to be avoided. Articles of steel, nickel, tin, zinc, or german-silver, will be coated with black and more or less non-adherent platinum; but by giving objects of these metals a preliminary thin electro-deposit of copper in the hot cyanide bath, they may be electro-platinized in the alkaline platinate bath equally as well as copper. The bath may be worked hot or cold, but it is recommended to work it at a temperature not exceeding 100° F. It may be diluted to one-half the strength indicated in the formula and still yield excellent results. The surface of the objects should be highly polished by buffing, or otherwise, prior to their introduction in the bath, if the resulting deposit is designed to be brilliant.

The deposition of platinum takes place promptly. In five minutes, a sufficiently heavy coating will be obtained for most purposes. The deposited metal is so soft, however, that it requires to be buffed very lightly. A heavier deposit will appear gray in color, but will accept the characteristic lustre of platinum beneath the burnisher.

The oxalate solution is prepared by dissolving one ounce of platinic hydrate in four ounces of oxalic acid and diluting the solution to the volume of one gallon with distilled water. The solution should be kept acidified by the occasional addition of some oxalic acid. The simplest plan of using this bath, and which requires no attention to proportions, is simply to work with a saturated solution of the oxalate, keeping an undissolved excess always present at the bottom of the vessel. An addition of a small quantity of oxalic acid now and again will be found advantageous. The double salts of oxalic acid with platinum and the alkalies may be formed by saturating the oxalate of the desired alkali with platinic hydrate and maintaining the bath in normal metallic strength by the presence of an undissolved residuum of platinous oxalate.

The double oxalates are not so soluble in water as the simple salt. The oxalate baths, both of single and double salts, may be worked cold or hot (though not to exceed 150° F.), with a current of comparatively low pressure. The metal will deposit bright, reguline and adherent on copper and brass. Other metallic objects must receive a preliminary coppering as above. The deposited metal is dense, with a steely appearance, and can be obtained of any desired thickness.

The deposit obtained in the oxalate baths is sensibly harder than that from the alkaline platinate bath, and will bear buffing tolerably well.

The phosphate bath may be prepared by the following formula:

1. Abstract of a paper read before the Chemical Section of the Franklin Institute, May 20, 1890.

Phosphoric acid, syrupy (sp. gr. 1.7)........	8 oz.
Platinic hydrate........................ ...	1–1½ oz.
Distilled water....	1 gallon.

The acid should be moderately diluted with distilled water, and the solution of the hydrate effected at the boiling temperature. Water should be added cautiously from time to time to supply that lost by evaporation. When solution has taken place, the same should be diluted with sufficient water to make the volume one gallon. The solution may be worked cold or warm to 100° F., and with a current much stronger than that required for the platinates and oxalates. The ammonio- (and sodio)- platinic phosphates may be formed from the simple phosphate by carefully neutralizing the solution of the phosphate with ammonia (or soda); then adding an excess of phosphoric acid, or enough to dissolve the precipitate formed and an additional quantity to ensure a moderate amount of free phosphoric acid in the bath. The phosphate baths will be maintained of normal strength by additions of platinic hydrate, the solutions of which will have to be assisted by heating the bath, preferably at the close of each day's work. The metal yielded by the electrolysis of these phosphate solutions is brilliant and adherent. It has the same steely appearance as that exhibited by the oxalate solutions, but to a less pronounced degree. The physical properties of the deposited metal are in other respects like those described in connection with that obtained from the oxalate baths.

CORRESPONDENCE.

ST. LOUIS.

Electric Railway Extensions—Conversion of Cable Roads to Electrical—A New Electric Light Company.

MR. JOHN SCULLIN, president of the Union Depot Railroad, is so well pleased with his electric road that he has given orders for the enlargement of the power-house, and the installment of 1000 additional horse-power. The Mound City Railway, of which Mr. Scullin is president, is being equipped for electric power, and will be supplied with current from the Union Depot power-house.

The Lindell Railway Company, although pushing their work with all vigor possible, will not be in operation on their down town lines short of 90 days.

The Cable and Western Railroad has been sold by order of Court. Lee, Higginson & Co., of Boston, were the successful bidders at $150,000. As a result of this the St. Louis and Suburban Railroad has been incorporated with a capital stock of $2,000,000 for the purpose of acquiring the old Cable and Western property, which property, including an electric railway franchise, has been transferred to the newly formed company. Preparations are being made for the electrical equipment, and as Lee, Higginson & Co. are heavily interested in the Thomson-Houston Electric Co., it is likely that the Thomson-Houston system will be used.

The Short electric cars are now in successful operation on the South end of the St. Louis Railroad. Eight cars with trailers are in use.

The Peoples' Gas and Electric Light Company have filed articles of incorporation, capital stock $50,000, fully paid. This company have a bill before the Municipal Assembly for a franchise.

ST. LOUIS, July 10, 1890.

CHICAGO.

Elevated Railroad Work—Pullman Street Car Shops.

IT is reported that work on the South Side Elevated Road, which is being built in the alleys between the houses, thereby not disfiguring the avenues and boulevards, will be resumed in the course of a few days, and that the second mile of the structure will be completed two weeks later. At the present time only one mile of the road is finished between Twenty-ninth and Thirty-ninth streets. The company cannot build further south because the ordinance only provides for a road from Thirty-ninth street to Van Buren, and at the north work is blocked by the property owners. A condemnation suit will shortly come up, and as soon as damages shall have been assessed and property owners satisfied work on the alley elevated road will begin. President Clark says all necessary material is on hand and that the actual work of constructing the next mile of the road will not require more than 10 days. He also says that by January 1st next, 4 miles of the road will be in operation, and that before the World's Fair opens the company will be able to land passengers at the entrance. The road will have branches to various southern and southwestern sections now being developed. According to President Clark every engine will haul 3 or 4 coaches, containing seventy-five persons each, and the trains will run every 5 minutes to enable about 4,000 people to reach the Fair from the heart of the city every hour. The road is to be provided with handsome stations. It is sincerely to be hoped that electric locomotives will be employed for operating this road, as their many advantages have been demonstrated in New York and elsewhere. Any addition to the present smoke nuisance by adding steam locomotives in the resident districts should be immediately vetoed. Not only can electricity do the work, but it can perform it more economically, more safely and in a better manner than by any other means, and an elevated suburban railway is an ideal point to locate an electrical system.

The new extension of the street car shops at Pullman is nearly completed and will be ready for use in a short time. Poles are being erected along the line of the electric railway there on which wires will be strung right away. It is rumored that the Westinghouse Company are considering a proposition from Mr. Pullman to erect a joint plant near Chicago for the construction of electric railway cars and electric motors. It is hoped to enlist Chicago capital in the enterprise, and if this is accomplished the arrangement proposed will be carried out with Mr. Pullman.

CHICAGO, July 11, 1890.

PITTSBURGH.

Double Deck Car Service—The Dahl Storage Battery—Electric Railway Franchises.

Rapid Transit Work.—Recognizing Faithful Service.—Trying to Use Electricity for Suicidal Purposes.

THE Pleasant Valley street railway company in this city is about to try the experiment of a novel car-service line, by using what is commonly called a double-decker. A number of workmen have been engaged in the construction of this car at the company's shops in Allegheny City. It is modelled after the double-deckers which have been very successfully used on the street car lines in London, England. The car is much longer than the present ones in use. It will have 14 windows on each side and an inside seating capacity of 42 passengers. On the roof are two long seats placed back to back except leaving sufficient space for the operation of the trolley pole. The upper deck seats will accommodate 28 passengers. The roof will be reached by means of steps placed at each end of the car.

Mr. Stephen Dahl, an electrician employed by the Pittsburg, Allegheny and Manchester Railroad Company, is now experimenting with a new storage battery system, for which it is claimed that the material used in its construction is exceedingly light, and therefore peculiarly adapted for transportation in a street car. If the system proves a success, the company intends to adopt it on its lines.

At the last meeting of city council, a large number of railroad franchises were granted to several corporations, all of them intending to operate electric railroad on their lines. These are: The Pittsburg and Mt. Lebanon Railway Company; the McKean Street Railway Company; the Jane Street Railway Company; the Arlington Avenue Railway Company, and the Bingham Street Railway Company. All these roads will be operated by electric motive power.

PITTSBURGH, July 4, 1890.

The procession for rapid transit is steadily moving along in this city. Several gangs of workmen are occupied on the different lines of the Duquesne Traction Company's road and the tracks have already been laid upon the major portion of the streets which this system is to traverse. The management is hurrying the work to its utmost and bids fair to make good its original promise that the roads shall be in running order by October. A similar activity is manifest on the Birmingham traction line. The latter is now building an addition to the Smithfield street bridge which will be exclusively utilized for the electric cars of the company.

The conductors and motor men of the Second Avenue Electric Railway Company had quite a treat given them a few days ago. On the fourth instant, the road was unusually busy, all the cars being run from early morning until late at night, and the men worked 15 hours without interruption. Ten thousand passengers were carried on the road that day and the management, to show its appreciation of the men's work, especially as not the slightest accident had occurred during the entire time, determined to give the employés a banquet. It is needless to say that this recognition of the men's work was very gratifying to them.

Alfred Ray, a well-known resident of Lima, O., attempted to commit suicide the other day by catching hold of the electric wires in that town. His wife however surprised him in the act and summoned several neighbors, who prevented Ray from accomplishing his wish. This is the first case on record in this part of the state, of an attempt to commit suicide through the agency of electricity.

July 11, 1890.

H. N. ROWELL has been appointed superintendent of telegraph of all the divisions of the Boston and Maine Railroad.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

THE SPECIFIC RESISTANCE OF COPPER.

[128.]—I have read with much interest the articles by Mr. Geo. B. Prescott, Jr., on "The Specific Resistance of Metals and Alloys" (ELECTRICAL ENGINEER, April 30 and May 7), for I have been experimenting in a similar direction a little during the past winter, and have produced samples exceeding in conductivity as much as three-quarters of one per cent., the figures laid down by Jenkin and Matthiessen.

I have just had a sample tested, which gives the following results:—Length, 8 feet 11 inches; mean diameter, .03423 inch.; weight, 14.441 grammes; temperature, 24.3° C., the resistance in legal ohms was .08083 observed; but R=.08057 by calculation as annealed wire.

MOSES G. FARMER.

Eliot, Me.

TELEGRAPH OPERATORS AS ELECTRICAL ENGINEERS.

[129.]—In your editorial relating to the New York *Sun's* article on the migration of telegraphers to other fields, you exhibit surprise at their endeavor to secure "promotion and riches" by a different route from that they started on, and make a few suggestions as to the probable cause.

Usually, operators start to learn their trade when very young, when twenty-five dollars a month seems a small fortune to them. As they get older, and the fascination wears off, the very monotony makes them dissatisfied, and with new responsibilities to shoulder, even if they reach the point where they receive the highest salary paid for telegraphic work, they seek to better themselves. Some enter other professions from a recognition of their adaptation for some particular pursuit, and fortunate is he who knows in what line he is best capable of success. The majority of those who examine the electrical field see everything through telegraphic eyes. Long years of service in this one line have placed a film over their eye-sight and they are imbued with the idea that the whole electrical field centers in the telegraph companies. The farthest they see is a chiefship with a probable increase of five or ten dollars to the pittance they now receive, with kicks from those above and abuse from those below. They do not see any benefit to be derived from four or five years' duty of quads and duplexes. If you ask any old operator why he does not study the higher branches of his profession, he will probably refer to a number of electricians in the telegraph service no better off than himself, or say "Some chief will think I want his position and I will be discharged the first chance they get at me." I have heard such remarks as this dozens of times, and it seems to be the prevailing idea. So long as this feeling exists, electrical engineering can expect no recruits from the telegraphers. Formerly, they were the only source to draw from, but with the placing of electrical engineering as a feature of college tuition, others have had the advantage of beginning in the higher paths without passing through the various grades of messenger, office boy and operator. Besides this, they get thorough instruction in the most essential part of engineering—mathematics. To be a *skilled* electrical engineer, one must be a good mathematician, a fair chemist, a clever mechanic, an inventor, and have sufficient energy to overcome all obstacles. This implies clear perception, sound judgment and keen reasoning powers; the ability to think for one's self without following the text-books, which are often very misleading.

When the time required to become an electrical expert is compared with the two or three years' study necessary to master some other profession, it is not surprising that telegraphers give it the go-by. They only see remuneration in becoming an Edison or a Jones, and think it useless to strive for something beyond their reach. They lack the necessary energy, and either enter other fields or remain where they are. Numbers of them would make fine electricians if they could only think with Bulwer that,

"Whoever, with an earnest soul,
Strives for some end from this low world afar;
Still upward travels, though he miss the goal,
And strays—but towards a star."

G. H. GOODFELLOW.

New York, July 12th, 1890.

CONSOLIDATION OF THE EDISON INTERESTS.

SOME weeks ago we gave first publicity to reports then current only in well informed circles as to the changes about to be made in the management of the Edison lighting and power interests. The course of events has since shown those reports to be accurate, as the changes then only contemplated have since been made, or will shortly be consummated. While the usual reticence in dealing with inquiries of the kind is strictly maintained at the offices of the Edison General Electric Company, we have reason to believe that our information as given below outlining the new departure is to be relied upon, and is thoroughly correct in almost every detail.

The reorganization is far more comprehensive and important than appears at first sight. If all that be said is true, it means, for the first thing, that Mr. Edison himself will devote by far the greater portion of his time to the development of apparatus for the Edison General Electric Company, in all its various fields of work, and especially in some of the newer ones. This statement seems to be borne out by the fact that Mr. Samuel Insull, who stands so close to Mr. Edison in a confidential relationship, is, in his new capacity of Second Vice-President of the company, taking, if possible, a more active part than ever in its business management, by having all the manufacturing and selling departments directly under his control and supervision. Mr. J. H. Herrick, the First Vice-President, will take charge of the finances, a matter of no small moment in such a large and progressive enterprise.

Another interesting feature of this new organization is that various districts have been created, each of which will handle the whole business in its given territory, subject, of course, to the central authority. Mr. C. D. Shain, of the United Edison Manufacturing Company, has been appointed manager of the Eastern District, with headquarters in New York City. Mr. O. T. Crosby, late of the Weems and Sprague Companies, has been appointed manager of the Southern District, with headquarters at New Orleans; Mr. G. W. Coster, formerly of the United Edison Company, has been appointed manager of the Rocky Mountain District, with headquarters at Denver. Mr. W. S. Heger is appointed manager of the Pacific Coast District, with headquarters at San Francisco. Last, but by no means least, comes the appointment at Chicago, for the Central District, and it is now understood that this position goes to Mr. John I. Beggs, who will resign as vice-president of the local Edison Company of this city to take it. One detail of this important mapping out of the country is that each district will also have its own engineer and auditor associated with the manager, and thus the work will be systemized and properly cared for at each point. The Canadian District will be managed by Mr. M. D. Barr, with headquarters at Toronto. These districts constitute branches of the Edison General Electric Company, all other agencies and interests being merged, losing not only their name but their identity.

This disposes of the arrangements outside New York. In the city, one of the first steps has been the shutting down of the old United Edison headquarters at 65 Fifth avenue. Pending the completion of the fine new Edison building, eight stories in height, running through from Broad street to New, the engineering department of the United Company has been located with one or two other divisions at 52 and 68 Broad street, while the accounting department goes to the headquarters at 44 Wall. At 16 and 18 Broad street, for the time, will be located the office of the Second Vice-President and of the factory and sales departments reporting to him. Mr. J. Muir will, thus, under the reorganization, be general manager of the railway department of the Edison General Electric Company. Mr. H. Ward Leonard will be general manager of the General Company's light and power department, including isolated plants and stationary motor work, as well as the transmission of power. Mr. J. F. Kelly will have charge of the wire department as its manager.

It is said that the vast manufacturing departments will each be in responsible hands, and that a division will be made of them into "mechanical" and "lamp manufacturing." Mr. John Kruesi, who has been Mr. Insull's "right hand" at Schenectady, will be general manager of the "mechanical" branch, and Mr. W. E. Gilmore, who is not generally known outside the Edison business, but has already earned a high reputation for ability and energy, will be his assistant at Schenectady. Mr. Kruesi's assistant at Bergmann & Co.'s, in this city, will be Mr. J. Hutchinson; and the Canadian shops will continue in charge of Mr. John Langton. The other main department, that of "incandescent lamp manufacturing," will be in charge of Mr. F. R. Upton, who will remain in practically the same position as before. With Mr. Insull, as his assistant at headquarters, will be Mr. S. D. Greene, now in charge temporarily at Chicago.

So far as can be ascertained, these are the main changes or new appointments, subject possibly to a slight modification or two. The plan for amalgamating the various interests and departments is one that has evidently been laid out in a masterly manner, and should be productive, as soon as a very little time has elapsed, of the best results in the development of a great industry.

REPORTS OF COMPANIES.

THE WESTINGHOUSE ELECTRIC COMPANY.

A meeting of the stockholders of the Westinghouse Electric Company took place on July 8, at the offices of the company in the Westinghouse Building, Pittsburgh, Pa. At this meeting the formal transfer of the stock of the Westinghouse Electric Company to the Westinghouse Electric and Manufacturing Company was made.

After that a proposition was laid before the stockholders for an increase of the capital stock of the company from $5,000,000 to $10,000,000. A resolution having been passed to this effect, the matter was put to a vote, which lasted an hour. At the termination of this period nearly 80,000 shares had been voted and every one had been cast in favor of the increase.

Mr. George Westinghouse, Jr., made the following statement to the meeting:

This company has now acquired the outstanding shares of the Westinghouse Electric Company, and by an action of a meeting of the stockholders of that company held July 7, 1890, has succeeded to its property and business.

The company began the manufacture and sale of continuous apparatus for incandescent lighting in 1886, which apparatus, however, could be commercially successful only for isolated lighting and central stations within moderate limits. Its capital was fixed at $5,000,000, with the expectation that that amount would meet the requirements of the business.

For the purpose of supplying apparatus for the distribution of electric light and power from central stations over large areas, it took up the alternating current system in 1886, up to which time none of the companies engaged in the business in the United States had considered that system commercially practicable; and it thus entered a field entirely its own.

To protect its business and successfully defend itself in any litigation that might be forced upon it by its competitors, the company found it desirable to fortify its patent position, and to that end acquired the control of the Consolidated Electric Lighting Company and the United States Electric Lighting Company, both of New York. The Consolidated Company was the successor of the Electro-Dynamic Light Company of New York, the first company organized in the United States for the manufacture and sale of electric incandescent lamps, and the owner of a large number of patents of date prior to those upon which rival companies were depending. The company purchased nearly one-half of the capital stock of the Consolidated Company, and subsequently leased it at a rental equal to 6 per cent. per annum on its capital of $2,500,000.

The United States Company was organized in 1878, a few weeks after the Electro-Dynamic Company, and was the successor of the oldest company in the United States for the manufacture of electric power apparatus, and also owned a large number of early patents covering every necessary detail of lighting and power plants. The company purchased $700,000 of a total of $1,500,000 capital stock of the United States Company, and leased its patents and business at a rental which will ultimately equal 6 per cent. per annum on its capital stock. In addition to their patents these two companies had large and flourishing businesses and manufacturing plants, which were also acquired by the leases.

These purchases have greatly increased the standing and influence of the company, which now owns and controls 632 patents relating to electric lighting and power, and has now pending over two hundred applications for patents for inventions necessary or desirable to the manufacture and operation of the latest improved forms of apparatus.

The success of the company is best illustrated by the report for 1889 already submitted, during which year the sales of the company and its leased companies amounted to $4,362,115.22, yielding a net profit of $729,307.87, after paying very heavy extraordinary charges incident to a new business of this character.

No branch of the electric business yields such large profits as the railway business, and the company has already entered this field. It has assured to itself the necessary patent protection to enable it to carry on the manufacture and sale of such appliances, and during the last three years has given close attention to the details of this class of apparatus; but it has refrained from selling the same until it could supply its customers with efficient and reliable equipments. The experience of users with the defective apparatus heretofore rushed out by other companies, fully justifies the wisdom of the company's action in this respect.

To-day the company is in receipt of orders and inquiries from all parts of the country, and has actually completed contracts for the equipment of 17 railways, aggregating $300,000, these orders having been received during the last 60 days. The volume of business offering to the company in this line indicates that its total out-put from the first of July this year to the first of July, 1891, may be doubled by the provision of adequate capital for carrying on this increased business, and with more than a corresponding increase in the returns. To enable the management to reap the greatest profit, the company should be placed in a position by its stockholders to do its business on a cash basis, and it should have available sufficient capital to take advantage of all profitable business offered to it.

The necessity for a large capital for a general electric business has been shown by the action of its two competitors: the Thomson-Houston Company having authority to issue $15,000,000, of which $11,500,000 have already been sold; while the Edison General Company has an issued capital of $12,000,000, which, according to its report to the Listing Committee of the New York Stock Exchange, is still insufficient to carry on an extended business.

The Board of Directors are of the opinion that a total increase in the capital stock of not less than $5,000,000, should now be authorized in order to provide for the future requirements of the company: $3,000,000 of which may be issued by the directors from time to time as in their judgment may be deemed best, and the issue of the remaining $2,000,000, to be subject to the approval of a special meeting of the stockholders called for that purpose.

It is proposed to issue forthwith to each stockholder of record on this date, an assignable right to subscribe on or before August 1, 1890, for one-half share of stock for each share now standing in his name on the books of the company, at $40 per share, this price being determined by a distribution or an allowance from the surplus earnings. Of this price one-quarter will be payable on August 1, one-quarter September 1, one-quarter October 1 and one-quarter November 1.

Mr. George Westinghouse, Jr., has agreed to take $1,250,000 of stock on the terms above indicated. If each of the other stockholders will subscribe to the number of shares to which he is entitled, the company will be enabled to provide for a large increase in its business. The Board believe it to be to the pecuniary interest of each stockholder to subscribe for his amount of stock, and thereby aid in increasing the earning capacity of the company, which will have the immediate effect of enhancing the value of the shares already outstanding, and of the shares which in this manner will be secured at a reduced rate.

The Board believed that great profit would accrue to the company by securing foreign patents on the more important of the inventions exploited by it in this country. This policy resulted in an order from the Metropolitan Electric Supply Company, Limited, of London, for a central station of 10,000 lights capacity, which has since been increased to 25,000. The station is now in operation with entire satisfaction, and is the most complete and perfect central station in Europe. A company known as the Westinghouse Electric Company, Limited, has been organized in London, to operate these patents, and this company has received in payment for the patents and the money expended in the development of that business £301,000 of the stock of that company, which is the controlling interest. The English company has recently received orders for other plants, and is in negotiations for others of a very extensive character, with every prospect of success. Indeed, the business abroad bids fair to reach proportions that will equal, if not be greater than, those of the parent company, and to be a source of great profit to it. The majority of the Board of the Westinghouse Electric Company, Limited, are also members of the Westinghouse Brake Company, Limited, of London, and the business is being conducted on the same lines which rendered the latter company so successful. Its operations are under the supervision and direction of Mr. H. M. Byllesby, the Vice President of this company, who is its Managing Director, and is now in England giving it his personal attention.

The following is a statement showing the financial condition of the company on June 1 of this year:

		June 1, 1890.
Cash		$ 74,508 58
Accounts receivable		1,341,535 56
Due from leased companies for cash advanced		539,591 33
Material in stock at cost		516,029 25
Material purchased for Newark factory		338,837 11
Real estate and buildings		401,854 75
Machinery, tools and fixtures		344,301 57
Stock in United States Electric Lighting, Consolidated and other companies, bought		1,597,664 18
Stocks and Bonds received in settlement of Accounts, and for Franchises		322,967 60
Stock of Westinghouse Electric Co., Limited		1,449,462 40
Charters, Franchises, etc		83,751 16
		$7,010,498 49
Patents: Some 632 patents covering the alternating current system, arc and incandescent, Tesla motor and other lines of manufacture of this company		4,111,312 09
Total Assets		$11,121,810 58
Liabilities.		
Bills payable, secured by collateral	$1,228,500 00	
Bills payable outstanding for merchandise	317,011 48	
Bills payable for sundries	116,666 66	
Accounts payable	368,541 61	
Bills payable, given in purchase of shares of United States Electric Lighting Co., payable $37,500 quarterly	575,000 00	
Bills payable given in purchase of Newark store-room stock, payable in monthly installments of about $15,000 each	324,269 48	
Cash advanced by Mr. George Westinghouse, Jr.	1,241,705 42	
	$4,161,694 00	
Capital stock	$4,998,150 00	
		$9,159,844 00
Surplus		$1,961,966 58

STOCKS AND BONDS.

WOOSTER, O.—The Wooster Schuyler Electric Light Co. has changed its name to the Wooster Electric Co. and increased its capital stock from $25,000 to $50,000.

THE THOMSON-HOUSTON DEBENTURE BOND COMPANY has been organized, and the first issue of bonds—$1,000,000—will be made within a week or 10 days.

THOMSON-HOUSTON STOCK.—The Thomson-Houston common stock, trusteed or "pooled" for 30 days, for sale, is now being held for 90 days more by the trustees, not a share having been withdrawn from the pool. The 120 days date from June 5.

THE SYRACUSE CONSOLIDATED STREET RAILWAY CO. is to issue $1,000,000 of first mortgage 5 per cent. 30-year gold bonds. The company consolidates nine systems with 30 miles of track, and is to adopt electricity for the whole. The roads are now earning about $200,000 gross and $75,000 net.

MALDEN, MASS.—Having lately increased its capital stock from $100,000 to $150,000, the Malden Electric Co. offers stockholders of record July 2 the right to subscribe until Aug. 15 for one new share at par, $100 for every two shares now held, payments to be made in cash on or before Aug. 15 Rights are assignable. The proceeds of the stock are for new plant, which promises to increase the income in greater ratio than the increase of capital. The company pays 8 per cent. on its present stock, and Treasurer C. W. Royce says it can do the same on the new capital.

NEW YORK SUBWAY BONDS.—First and second mortgages on the franchises, working apparatus, etc., of the Consolidated Telegraph and Electrical Subway Company, consisting of the telegraph, electric light and telephone companies, and the Edison Illuminating Company, of this city, were filed recently in the Register's office. The first mortgage is executed to the Atlantic and the second to the Mercantile Trust Company. The mortgages are to secure an issue of $4,750,000 worth of bonds, or $2,375,000 each. The telegraph and telephone companies will issue $1,125,000 worth of bonds, the electric light companies an equal amount, and the Edison Company $125,000 under each mortgage. The issue will be of 6 per cent. bonds for $1,000 each, payable June 1, 1940, or redeemable earlier, at the option of the company, after six months' notice, on payment of accrued interest and 10 per cent. premium on the par value.

The issue of bonds was decided on at a meeting of the Board of Directors of the Consolidated Company held May 20 last to raise money for the construction of subways throughout the city.

SOCIETY AND CLUB NOTES.

THE ATLANTA ELECTRIC CLUB.

The Atlanta (Ga.) Electric Club recently organized with a charter membership of about forty members, and fifteen recent applications for members. Their club rooms are located in the direct business centre of the city, very tastefully furnished, and lighted with a unique arrangement of incandescent lights supplied by the Thomson-Houston Co. They have telephone connections, call boxes with the Western Union and Postal service, and instruments connecting with the same companies, phonograph, and phonograph-graphophone, reading room, billiard and pool tables, grand piano, and everything arranged for the best comfort of the members, and their out of town friends. All the principal electrical men of Atlanta and vicinity are members, and the club is an assured success.

LEGAL NOTES.

A NEW YORK SUBWAY SUIT.

The North American Underground Telegraph and Electric Company has brought suit in the Supreme Court against the Consolidated Telegraph and Electrical Subway Company and the New York Underground Telegraph Company for $2,500,000 damages and to compel the subway company to take down overhead wires in this city and place them in a conduit owned by the plaintiff. It is charged that the Western Union Telegraph Company and the American Bell Telephone Company have gained control of the subway company in order to prevent the further tearing down of overhead wires.

In March, 1888, the complaint sets forth, the subway company agreed with the plaintiff corporation for the use and operation of the Johnstone underground system. The New York Underground Telegraph Company became a party to the agreement, being possessed of certain grants and privileges. The Johnstone system was adopted and a number of miles of the conduit was laid. Then the work was suddenly suspended.

This is laid at the door of the Western Union and the Bell Company, controlling the Metropolitan Telegraph and Telephone Company, and through it the subway company. It is further charged that the defendants have resorted to laying useless conduits in order to make the public believe that an underground system was impracticable.

ELECTRIC RAILWAY LITIGATION IN PITTSBURGH.

A special dispatch from Pittsburgh of July 7, says:—Three bills in equity and one action at law were filed in the United States Circuit Court to-day by the Westinghouse electric people. The titles of the suits are George Westinghouse, Jr., *vs.* The Wilkinsburg Electric Company; The Westinghouse Electric Company *vs.* The Wilkinsburg Electric Company; The Westinghouse Electric Company *vs.* The Second Avenue Passenger Railway Company, and the Westinghouse Electric and Manufacturing Company *vs.* The Second Avenue Passenger Railway Company.

In the action at law damages are claimed to the amount of $50,000. The Thomson-Houston company is aimed at in the action brought against the Second avenue electric line, as the company is operating the Thomson-Houston system.

DELAYED TELEGRAM.—HANNAH JOSEPH vs. W. U. TEL. CO.

The Western Union Telegraph Company was sued for $25,000 in the Chicago Federal Court by Mrs. Hannah Joseph. The plaintiff is the wife of a traveling salesman who, while at Paxton, Ill., one Saturday evening, telegraphed his wife that he would be home the following day. He did not come, and Mrs. Joseph was seized with hysterics, which a physician said were the commencement of a more serious disorder. Mrs. Joseph sent a message to her husband asking him why he did not come, but did not receive a reply until the following day. During all that time she suffered great agony. Judge Gresham heard the evidence yesterday and instructed the jury that, while the company was liable for the delay in delivering the telegrams, Mrs. Joseph's sufferings commenced before she sent the message, and she could only recover the price paid for tolls. A verdict for 25 cents was returned.

INVENTORS' RECORD.

Patents issued July 8, 1890.

Alarms and Signals:—*Electric Signaling Apparatus*, G. B. Lehy, 431,597. *Signaling Apparatus*, G. B. Lehy, 431,598. *Boiler Alarm*, D. Focer, 431,885. *Automatic Fire-Alarms*, H. E. Jacobs,, 431,979.

Conductors, Conduits and Insulators:—*Subway for Electric Cables*, W. L. Parsley, 431,780. *Metallic Pole for Electric Wires*, etc., J. P. Schnieder and D. K. Carson, 431,955.

Distribution:—*Apparatus for Electrical Conversion*, E. N. Dickerson, Jr., 431,879.

Dynamos and Motors:—*Magneto-Electric Machine*, A. S. Colgate, 431,559. *Regulator for Dynamo Electric Machines*, G. A. Polson, 431,618. *Electric Motor Apparatus*, S. C. C. Currie, 431,649. *Dynamo*, E. H. Johnson, 431,812.

Galvanic Batteries:—*Galvanic Battery*, C. R. Goodwin, 431,742. *Composition for Porous Carbon Structures*, C. R. Goodwin, 431,743. *Process of Forming Porous Pots for Voltaic Batteries*, C. R. Goodwin, 431,968.

Lamps and Appurtenances:—*Incandescent Lamp Socket*, J. J. Wood, 431,681. *Means for Attaching and Detaching Electric Lamp Bulbs*, S. J. Jacobs, 431,721. *Incandescent Lamp*, G. R. Lean, 431,776.

Medical and Surgical:—*Electro-Therapeutic Appliance*, A. W. Jackson, 431,978.

Miscellaneous:—*Electric Ceiling Block*, W. C. Bryant, 431,551. *System of Defending Harbors by Submarine Torpedoes*, A. G. Donnelly, 431,565. *Means for Moving and Guiding Turning, Engraving or Planing Tools*, G. M. Guerrant, 431,578. *Pneumatic Dispatch Tube*, S. F. Leake, 431,699. *Pneumatic Dispatch Tube Receiver*, S. F. Leake, 431,700 and 431,701. *Thermal Cut-Out*, L. B. Favor, 431,718. *Electric Device for Slaughtering Animals*, J. D. Miller and J. A. Doflemyre, 431,777. *Automatic Coin-Controlled Phonograph*, L. F. Douglass, 431,883. *Passenger Recorder*, A. Torrey, 432,008.

Railways and Appliances:—*Conduit for Electric Railways*, J. H. Wehrle, 431,633. *Electric Railway*, J. H. Wehrle, 431,631. *Signaling Apparatus*, J. H. McCartney, 431,671. *Trolley-Pole Supporting Mechanism*, J. M. Anderson, 431,684. *Electric Railway*, S. H. Short, 431,711. *Electric Railway*, R. M. Hunter, 431,720. *Electric-Railway Motor*, F. J. Sprague, 431,823. *Rail Support, Grip and Conductor*, W. S. Hull and J. C. Anderson, 431,846. *Hanger for Trolley Wires*, J. T. Henry, 431,973. *Electric Railway*, R. M. Hunter, 431,977.

Secondary Batteries:—*Apparatus for Preparing Electric Accumulator Plates*, C. F. Pollak, 431,617.

Telegraphs:—*Private Line Telegraphy*, P. B. Delany, 431,651. *Printing Telegraph*, G. B. Scott, 431,784. *Automatic Telegraphy*, F. Anderson, 431,793. *Automatic Telegraph*, F. Anderson, 431,794. *Printing Telegraph*, A. T. McCoy, 431,987.

Telephones and Appliances:—*Aural Attachment for Telephone Receivers*, E. C. Hess, 431,810. *Transfer-Connecting Apparatus for Multiple Switch-Boards*, E. M. Barton, 431,962.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

THE CLARK AUTOMATIC SAFETY DEVICE.

The Mayor and the Board of Aldermen of Newburgh visited the station of the Newburgh Electric Light & Power Co., recently, inspecting the operation of the Clark automatic safety device, manufactured by the Clark Electric Co., of the Corbin Building, this city. This is an automatic shut off that is intended to immediately cut off the current in the arc system in case of an accident by which the wire is broken or circuit interrupted. One of the great dangers at the present time in case a wire breaks is that the circuit may be completed by some adjacent object, and the current allowed to resume its operation. It is claimed that the safety device will immediately cut off the entire current of the circuit to which it may be applied. The appliance consists of a coil that is magnetized when the current is in action. The magnet then attracts and holds an armature, which, in its turn, holds a spring switch. When the current is cut off the magnet loses its power, the armature falls, the switch is then released, and springing back, cuts off the current from the dynamo. Thus it is claimed that if the weight of snow or ice upon a wire should break it, the device would cut off the supply at the station and all danger would disappear. The principle was applied in a practical manner by cutting a wire. The operation was perfect. The device cut off the current immediately and all the lamps connected with that circuit were at once extinguished. The device is the invention of Mr. Ernest P. Clark, the electrician of the Clark Electric Company. THE ELECTRICAL ENGINEER for April 30 gave a complete illustrated description of the device.

ROCHESTER'S NEW ELECTRIC RAILWAYS.

Work is now busily going on at Rochester, N. Y., in connection with the Short electric railway that is to be installed there. The equipment will include 50 miles of track and 100 new cars.

The power house, which is now in course of construction, will occupy all the space between the race, Mill street, Center street and the New York Central tracks. The site was purchased from the Central railroad company for $20,000. The power house will be of brick, two stories in height. Its smoke-stack will be 150 feet high, and its entire cost $60,000. This sum does not include the equipment nor the price paid the Central for the property. Besides the power plant, there will be located in the building a complete machine shop in which will be lathes, planers and all the machinery necessary for a fully equipped iron working shop. It will be the policy of the company to do its own repairing.

The power plant to be put in at the present time will consist of four Heine boilers, having a total capacity of 1,600 horse power; seven Ball compound condensing triple expansion engines, three of 300 horse power, three of 120 horse power and one of sixty horse power. The engines and boilers are being constructed by the Ball Engine Company, of Erie. The location of the power house was chosen with reference to the convenience with which coal can be dumped directly from the railroad cars into the company's bins. For the present use of the company there will be nine Brush dynamos of 120 horse power each, but the power house is built upon plans which anticipate the extension of the plant to nearly double its present capacity. The entire cost of building and plant cannot be less than $200,000—this, however, is only an estimate. The whole electric railway service will cost about $2,000,000.

MR. HAROLD BINNEY, M. E. E. E.

Having resigned his position as an assistant examiner, U. S. Patent Office, in class electricity, Mr. Harold Binney has taken up the profession of patent soliciting, etc., in this city, and has associated himself with Mr. Gilbert M. Plympton, a well-known patent practitioner and counselor at law. These gentlemen have their offices at 245 Broadway, and there carry on their business of obtaining patents for inventions and of attending to patent litigation in the courts. Mr. Binney, has of course, had special facilities in the electrical field, and some of his contributions to electrical literature will probably be familiar to our readers.

MR. W. J. HAMMER.

Few men are so well known in the electric lighting field as Mr. W. J. Hammer, who has just established himself as an electrical expert and consulting electrical engineer in the Temple Court Annex on Nassau street. Mr. Hammer did much of the pioneer Edison electric lighting work in this country, England and Germany, and enjoys not only the closest familiarity with electrical work in all its details but the widest possible acquaintance everywhere. It deserves mention also that he is possessed of unusual taste, as shown in his management of the great Edison exhibits at Cincinnati, and more especially at Paris last year, at the Centennial Exposition, where a comprehensive display was made of all of Mr. Edison's inventions. Mr. Hammer has in his office many interesting mementoes of that great Exposition, but what he most values is his unique collection of incandescent lamps. This collection, placed in cabinets so that the lamps may be easily examined, embraces some 400 or 500 specimens, from the very earliest to the latest. Mr. Hammer has been offered many thousand dollars for the collection, but refuses to part with it.

Mr. Hammer's specialties, the incandescent lamp detacher and his "electricians' pocket tool," are handled by The E. S. Greeley & Co., of this city. From some of his other inventions he also draws neat royalties. At present he is devoting himself entirely to engineering work, and his services have already been retained by a number of parties familiar with their value.

BISHOP CABLES IN NEW YORK HARBOR.

Mr. H. A. Reed, the secretary and manager of the Bishop Gutta Percha Company, 420–426 East 25th street, sends us the following interesting data:—

In the summer of 1887 we were requested to make specifications for a submarine cable with two conductors which should carry current from the light house station, Staten Island, six thousand feet under the waters of the bay, and light a fifty candle-power lamp on a buoy on Robbin's Reef; the current not to exceed 250 volts. We made the specifications (and afterwards made the cable) as follows: Strand three No. 16 B. & S. copper wires, insulate with gutta percha to a diameter equal to that of No. 1 wire, B. & S. Strand the two conductors with suitable laterals, serve with jute and armor with 18 No. 7 galvanized wires. The cable was laid in the fall of 1887, and worked so satisfactorily that similar cables were ordered and made by us the following summer for lighting the six buoys in Gedney's channel. As the current had to be carried about three miles for the channel buoys, we used more copper, viz.: Seven No. 18 B. & S., but about the same thickness of insulation (a trifle over 1-10" pure gutta percha). These cables have worked with Edison dynamo without interruption, except from marine accidents, to the present time.

About four months since Lieut. John Millis, under whose supervision these lights are, wrote me asking whether I thought the cables would carry an alternating current of 1,000 volts. In answer I told him I had no doubt that the cables would each stand 2,000 volts direct or 1,000 volts alternating, but advised him to first experiment with the Robbin's Reef cable, which was not now in use. I give the result in his own words:—

TOMPKINSVILLE, N. Y., June 30, 1890.

MR. HENRY A. REED, Secretary Bishop Gutta Percha Company, New York.

Dear Sir: It may interest you to learn that the experiment of sending an alternating current of 1,000 volts potential through the cable made by you for the electric lighted buoy off Robbin's Reef, New York harbor, proved an entire success. There was *no leakage* and *no injury* to the cable.

Respectfully yours,

JOHN MILLIS,
First Lieutenant of Engineers, U. S. Army.

DESTRUCTION OF INSULATORS AND WIRES BY COWBOYS.

Every telegraph wire on the Union Pacific Railway near Sydney, Neb., was interrupted on July 10, and all communication with the West and Pacific coast by this, the main route of the Western Union Telegraph Company, was completely severed from daylight until late in the afternoon.

A lot of cowboys who had been working on a round-up near Sydney visited that town at night, and, when they had exhausted all the pleasures of the metropolis of Cheyenne county, at daylight they mounted their ponies and proceeded a few miles west of the town, where they set up a target against a telegraph pole. They spent some time in hitting it from various distances, but, the mark proving too easy for their skill, they turned their attention to the insulators and wires, and only desisted when they had knocked off all the insulators and cut every wire with their bullets. The Western Union Telegraph Company sent repairers to the scene, but it took them all day to repair the damage.

THE NOVELTY ELECTRICAL SUPPLY MANUFACTURING CO.

All the arrangements have now been completed for the opening of the largest supply house in Cincinnati, under the auspices of the above well-known company, of 83 John street, that city. They now have over $100,000 worth of material in the way of electric light and electric railway supplies on the road to Cincinnati, and to arrive immediately, and they expect to have their new building ready in shape to do business by the 15th July. They have been very fortunate in the last few weeks in receiving large orders for their electric railway supplies, especially iron poles and pole tops, and may confidently count on a large and growing trade in their many meritorious novelties and specialties. Mr. E. P. Morris is the president and manager of the company and Mr. P. B. Chaney, secretary and treasurer.

THE BURTON ELECTRIC HEATER.

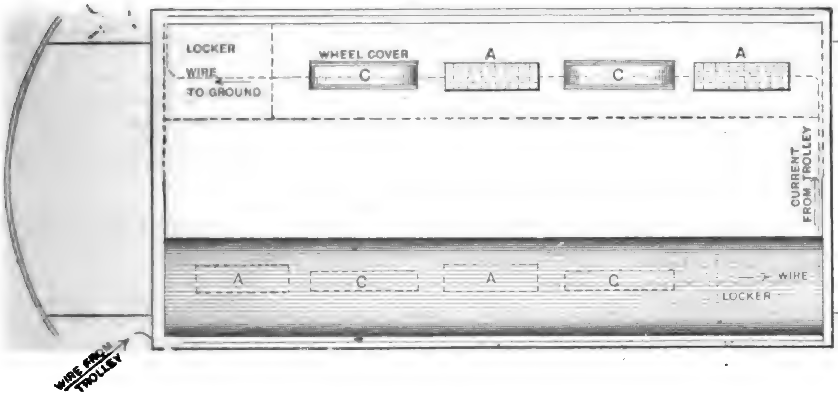
THE Burton electric heater has come to be recognized as an invaluable part of the equipment of an electric railway. It is manufactured by the Burton Electric Company, of Richmond, Va. For our illustrations we are indebted to the Electric Merchandise Co., 11 Adams street, Chicago, who are agents for the sale of the heaters. Fig. 3 shows two views of this heater. One represents it with the top on and ready for use, and the other with the top off, exposing the arrangement of the resistance wire on the inside. Before use this is covered with dry powdered fire clay and the top screwed down, care being taken to have the joints thoroughly packed to prevent the escape of the fire clay. The outer casing is of ordinary cast iron having a coating of asphalt or other varnish, and its dimensions must be such as will be suited to the space it is to occupy. In its adaptation to electric cars, it is made 27 inches long, eight inches wide, and is mounted on iron legs which raise it about four inches from the car floor. Fig. 1 is a ground plan of an electric car, showing the position of the heaters A, A, A, A. Fig. 2 is a cross section of the same, showing the heater under the seat resting on a tin or zinc reflector B, which throws the heat into the body of the car. Fig. 4 is a diagram showing the wiring of the heaters by which their efficiency is very much increased. By referring to this it will be seen that two switches, one line and two ground connections, are necessary to get the best results. The line connections should be made with the trolley wire which usually runs down in the corner of the car before it enters the motor switch on the platform. The ground connections should be made with the iron side bar on the motor truck, one on each side.

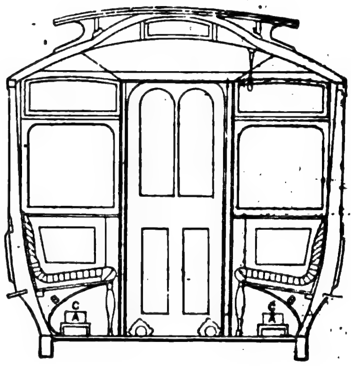
PEARCE & JONES.

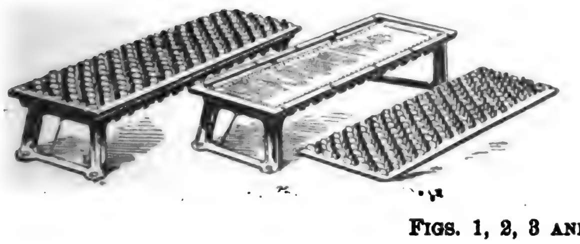
THE above named concern has been in existence for the last 18 years, and is therefore one of the oldest, as it certainly is one of the best known, in the business. The various products of the firm have long enjoyed an excellent reputation, and their skill as electrical mechanicians has often been called into requisition. It will be of general interest, therefore, to the electrical trade to learn that the firm have now dissolved partnership, Mr. James Jones retiring. Mr. Frederick Pearce, the remaining partner, succeeds to the business of the concern as manufacturing electricians, and will carry it on under his personal supervision at the old address, 77 and 79 John street, this city. Mr. Pearce will be happy to see the old friends of the business there, and will be glad to receive commissions from those who have not yet entrusted him with orders. He has the general good wishes for his success and prosperity under the new conditions.

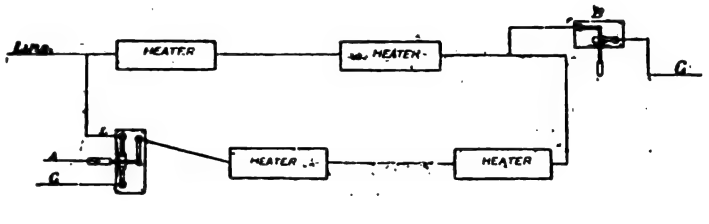
ARMINGTON & SIMS ENGINE CO.

The Armington & Sims Engine Co., Providence, R. I., have been enjoying a remarkably good business, and report that June was the best month they ever had. They have just issued a very tasteful and beautiful souvenir of Providence, that is highly prized by all recipients of it. Mr. G. C. Sims, who is one of the Rhode Island Commissioners for the World's Fair of 1893, has just returned home from the meeting of the National and State Commissions in Chicago.









FIGS. 1, 2, 3 AND 4.—THE BURTON ELECTRIC HEATER.

By this method of making these connections these heaters are entirely independent of the motors; and, besides, there could be no possibility of danger to workmen while oiling or repairing the motors.

For the special service of warming electric railway cars, the electrical resistance of the heaters is so regulated that on a 450 volt circuit, connected in series of four, they will use three amperes of current. When, therefore, the handle of the switch A is turned on L (shunt from line connection) and the switch B closed, the heaters are thrown in series of two for a short time only, causing the use of six amperes of current in each set. When a sufficiently high temperature has been attained in these—which will be in 15 or 20 minutes—the handle A is turned on G (ground connection) and the switch B opened. This causes them to be thrown in series of four, when the heat will be maintained in them for a long time without being appreciably lowered, with the use of only three amperes of current.

The electric railways which have been equipped with this device are emphatic in their praise of it. The committee on science and the arts, of the Franklin Institute, recommended the award of the Scott legacy prize to this heater.

Samples will be shown and prices given at the company's office, 11 Adams street, Chicago.

THE CROCKER-WHEELER MOTOR CO.

This young company moved into its West Fourteenth street factory only a few months ago, but has already increased its facilities, extending its floor area and putting in a number of new tools, etc. A large force is now busy turning out motors of the various sizes. The demand for fan motors during the past month has been phenomenal and it has been well nigh impossible to keep pace with them, in spite of every effort. The company has several special pieces of work in hand, and is much gratified at the manner in which its motors are being received by the electrical trade and the public generally.

THE CARD ELECTRIC MOTOR AND DYNAMO CO.

This progressive company of Cincinnati, O., has, at a recent meeting of the stockholders, decided to increase its capital so as to treble its present capacity. It has been compelled to cancel a number of orders owing to its inability to furnish the desired motors promptly. The factory at John and Front streets is in full blast, and the present capacity is sorely overtaxed. While the card motor is not yet generally known in the east, it has an excellent record in the middle and western states.

THE BAKER COMMON SENSE OIL FILTER.

Mr. F. A. Ross, the superintendent of the Livingston, Mont., Electric Light Co., wrote as follows a short time since to Mr. W. E. Crane, of 421 Thirteenth avenue, S. E., Minneapolis, relative to his filters: "Enclosed find exchange in payment of two 'Common Sense' oil filters, the last ordered by wire a few days since. I rather regret this last order, for I find that one filter will do all our work, and so well, that another is really unnecessary. I have had another make of filter in use, but in spite of all we could do, it would not return our oil as clear as we required it to be, and in consequence we had all the cans, pails, etc., we could muster filled with oil. I had not tested your filter for the amount of work it would do, as I wished to reserve it for the dynamos exclusively. I thought another was needed, if I wanted to keep engine oil separate. But such separation is unnecessary. Your filter seems to return all oil fed to it in an exceedingly pure condition. I have watched its action very carefully, and have taken many bottle samples, setting them aside for settlement and sediment; but have found nothing of the kind that the eye could detect. I must say, it is thoroughly 'common sense' in principle, and I congratulate you on having as neat and effective an article in hand."

ST. LOUIS TRADE NOTES.

The St. Louis Car Co. are busy with orders. Aside from their usual run of orders for cable and horse cars they are filling the following orders for electric cars: Thirty 24-foot summer cars, mounted on Thomson-Houston motor trucks, for Indianapolis, Ind.; twelve 16-foot closed cars, on Thomson-Houston motor trucks, for Peoria, Ills.; three 16-foot closed cars on Thomson-Houston 20 h. p. (single) motor trucks for Hannibal, Mo.; ten 24-foot summer cars mounted on Sprague motor trucks, for Los Angeles, Cal.; and five 18-foot cars, with Short motor trucks, for Muskegon, Mich.

The Laclede Car Co. have in hand the following orders for electric cars: 120 motor cars to be fitted with Sprague motors for the Minneapolis St. Railway Co.; fourteen 30 foot motor cars—Sprague motors—for Denver, Col.; eight cars, on Thomson-Houston motor trucks, for Streator, Ills.; twenty cars, on Thomson Houston motor trucks, for Duluth, Minn.; and eight cars—Westinghouse system—for Austin, Tex. They also have their usual share of orders for cable and horse cars.

NEW ENGLAND TRADE NOTES.

The Perkins' Electric Lamp Company, of Hartford, Conn., are having a remarkable demand for their incandescent lamps, and they have just completed arrangements by which they now can manufacture 5,000 lamps a day. Considering that little more than a year ago they were only making about 500 a day, it goes without saying that the Perkins' lamp must possess great merit, and is being pushed by an energetic and able management.

The Wainwright Manufacturing Company of Massachusetts have recently supplied the following heaters to electric light and power companies; Plymouth Electric Light Company, Plymouth, Mass., 250 h. p.; Schuyler Electric Light Company, Middletown, Conn., 150 h. p.; Stillwater Gas and Electric Light Company, Stillwater, Minn., 150 h. p.; Waltham Gas and Electric Company, Waltham, Mass., 300 h- p.; the Electric Light Department, City of Easton, Pa., 400 h. p.

The Wright Electric Engineering Company, of Boston, are at present making large extensions in outside construction work at East Weymouth. They will use about 135 poles and 12½ miles of wire. They have recently added 44 lights to the upper dining-room of the American House, Boston, and are installing 150 lights in the Surfside Hotel, Nantucket, Mass., which will be run on an alternating circuit from the Nantucket station, 2½ miles away. At Nantucket Beach the Wright Company are putting in an arc plant for illuminating the grounds of the Nantucket Hotel, Frank Ridlon & Co. furnishing the Brush dynamo. Besides a number of smaller jobs, they are also preparing complete station plans for Clinton, Mass., of 300 h. p., with an ultimate 600 h. p. capacity; and for the Derby Gas Company, Birmingham, Conn., who intend building a new station in which horizontal turbine wheels will be used geared direct to the countershaft.

The New England Electric Company have received an order from the Boston *Globe* for a 35 horse-power motor, to be used for running their "jumbo" printing press. The motor will sit in the pit with the press, and will gear direct on the shaft. It will be started and stopped and run at various speeds by the lever of the press. It will thus enable the press to run entirely independent of boilers and engines, and will always be in readiness to start up. The current will be taken from the two Edison circuits, both of which enter the *Globe* office, so that it can be run from either station. The New England Company are also in receipt of orders from the Edison Illuminating Company of Boston for a 10 and a 25 horse-power motor for elevator purposes in their new station, and a 10 h. p. motor for elevator in the Tufts College estate on Summer street. The contract for the increase and complete equipment on the Sprague system of the Naumkeag Street Railway Company has been closed this past week. The order provides for the change of the six 15 h. p. cars to six 30 h. p. cars, and thirty-five additional 30 h. p. cars, and the equipment of about 59 miles of track with the overhead system. The Naumkeag road was recently bought up by a strong syndicate, and the order comes from them.

WESTERN TRADE NOTES.

Mr. Charles G. Armstrong, manager of the house goods department of the Great Western Electric Supply Company, has gone on a business trip East, to purchase a general line of supplies. He will visit Boston, New York and Philadelphia, and perhaps some other points.

Mr. G. A. Edward Kohler, manager of the Chicago office of the Eddy Electric Manufacturing Company, of Windsor, Conn., with offices in the Rookery, has just sold two motors of 2 and 4 h. p., respectively, to the National Bank of Illinois, where they will be employed for ventilating purposes in connection with the Blackman ventilating fan.

Mr. W. H. Harding, the manager of the South Side Electric Company, is making rapid progress with his new station, at the corner of State and 20th streets. This station is equipped with the Ft. Wayne Electric Company's apparatus, Slattery induction system, and will start out with a capacity of 4,000 lights, the total capacity for which the station is at present designed being 10,000 lights.

Mr. Fritz Goldenzweig, an electrical and mechanical engineer, of Vienna, Austria, was a visitor at this office this week. He is investigating electrical matters in this country and has visited the large cities and proposes to spend a week or so in Chicago. Mr. Goldenzweiz is looking for anything good to take back with him to introduce across the water. He is stopping at the Palmer House and makes his headquarters at the office of The Electrical Engineer.

Mr. M. M. M. Slattery, the inventor of the induction system so named, which is manufactured by the Fort Wayne Electric Company, is in town for a few days, and is stopping at the Auditorium. Mr. Slattery speaks very encouragingly of the future, and has some good things in hand which he is working out, and when placed upon the market will show some novel and remarkable developments. His new alternating motors may be expected in the near future to be largely introduced, and of a new storage battery upon which he is working great things are promised.

The Great Western Electric Supply Company have just brought out a handsome little catalogue of their railway department supplies. It is merely intended as a preliminary to their catalogue, which will be ready shortly, but nevertheless contains some handsome cuts and much useful descriptive matter. It is devoted to street railway electric supplies, among which may be mentioned curve brackets, trolley line insulators, poles, span wire ratchets, gears, switches and car material, and forms a neat little book with quite a fund of information.

The Hazelton Tripod Boiler Company, 170 Twenty-second street, Chicago, report their well-known boilers to be in large demand. These boilers have given remarkable satisfaction wherever introduced. They have two large boilers of 500 horse-power each, in the street railway cable station, at State and Twentieth streets, the great success of which is shown in the emphatic statement made by the engineer and staff there that "they can't be beaten." The merits of these boilers will repay careful investigation by intending purchasers of steam boilers.

The Chicago Water Motor Company, 88 Lake street, Chicago, are introducing a new ceiling fan which is intended to be operated by electric motor, steam or water motor. They manufacture a special water motor for small powers for this kind of work. The same motors might be conveniently employed for small isolated plants, the motor driving a small dynamo. Their fans are very handsome and highly efficient. Central station men who are furnishing power for operating motors and fan outfits should look this matter up, as very favorable terms can be made by the company.

Bleckert & Nelson, successors to the well-known firm of Noyes Brothers, manufacturers of electric light, combination and gas fixtures, 85 and 87 Fifth avenue, are very busy making preparations for their heavy fall trade. They have installed a lot of new machinery and very largely increased the manufacturing facilities of the firm. They make a specialty of furnishing supply and construction companies with electric brackets and also manufacture electroliers and combination fixtures from special designs. They are turning out some very beautiful and tasteful work, and carry a large stock and very choice selection of goods.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, JULY 23, 1890. No. 116

The little that is known is a great and wonderful indication of that which is to be known.—Faraday.

ELECTRIC MOTOR VS. STEAM LOCOMOTIVE.

THE accurate data available as to the cost of operation, power consumed, etc., by electric street cars may be considered to furnish an adequate guide to the estimation of the similar items for electric motors of larger power intended to replace steam locomotives, such as those employed on the elevated railways of this city. We are, therefore, hardly prepared to accept the statements contained in a paper read by Mr. Lincoln Moss, at the recent meeting of the Society of Civil Engineers, in which he draws a comparison between the steam locomotive and the electric motor employed on the Ninth Avenue elevated road in this city. Mr. Moss determines that with good stationary engines, and with an efficiency of *fifteen per cent.* from the engine to the motor, the cost of one net horse-power hour by electricity would be $3\frac{1}{10}$ cents; while in the case of the steam locomotive the total cost per net horse-power hour is $1\frac{3}{10}$ cents; thus making the ratio 1 to $2\frac{38}{100}$ in favor of steam direct. The assumption of an efficiency of fifteen per cent. as a general figure from tests involving the operation of but a single experimental motor on the line is wildly absurd in the light of the results obtained in street railway work, where repeated tests have shown that 50 per cent. efficiency can be counted on, with the conditions far less favorable than those existing on the elevated railroads. This foolish, fallacious assumption is indeed quite on a par with many of the statements put forward by Mr. Moss to account for the losses. Thus we are gravely told that "the general economy and efficiency are greatest when a certain ratio of speed exists between the generator and motor armatures. Usually this ratio is as 2 to 1, the motor armature revolving but half as rapidly as the generator's armature." We are also seriously informed that in electric motors "the economy is greatest, other things being equal, *when the load is lightest.*" These puerile statements, we think, are sufficient to demonstrate that the conclusions arrived at by the author are apt to be, as they in fact are, entirely valueless; and we have only drawn attention to them as another example of the ignorance which unfortunately still exists among otherwise probably well-informed engineers regarding the action of the electric motor and the well-established data as to its practical economy. We are surprised that a body like the Civil Engineers should accept and listen to such a paper.

CHANGES BY THE SENATE IN THE McKINLEY TARIFF BILL.

AMONG the modifications made by the Senate in the provisions of the McKinley tariff bill, those touching copper and mica are of special interest to electrical manufacturers. The Senate Committee on Finance, in their report, greatly reduce the rates of duty on copper ores and on unmanufactured copper from those of the McKinley bill passed by the House of Representatives; while they keep mica on the free list, where it has always been and would remain but for the rise of economists of the McKinley variety.

As respects copper, the House bill cut the existing duties of $2\frac{1}{2}$ cents per pound on ores and 4 cents on plates, bars, ingots and pigs, just one-half; adopting the rates of $1\frac{1}{4}$ cents and 2 cents respectively. The Senate Committee proposes $\frac{1}{2}$ cent per lb. on copper ores and $1\frac{1}{4}$ cents on plates, bars, ingots and pigs. Neither House nor Senate proposes any changes in the existing high duties on manufactured copper, viz: 35 per cent. on rolled plates, sheets, rods, etc; and 45 per cent. on wire. We know of no arguments whatever for the retention of any duty on unmanufactured copper. The reasons against it are so obvious that good protectionists, like the New York *Tribune* and Congressman Butterworth, have been outspoken in denouncing it. But, even though no tariff bill pass both houses of the present Congress, the successive abatements proposed by the House bill and the Senate report make a record that will strengthen the hands of tariff reformers in future work.

Mica has always been on the free list. The owners of a few mica mines in North Carolina and New Hampshire, not making as much money as they would like out of their business, betook themselves to Washington last winter—as all producers of whatsoever commodities desiring more money for their products had been invited to do—and told a piteous tale of their necessities to the McKinley Committee. They wanted 50 cents to a dollar a pound duty put upon mica. They did not want an *ad valorem* rate: for, they said, nobody could tell what a ton of mica was worth till split and cut to sizes; importers would get the better of them by undervaluation. The committee, like the unjust judge under pressure of importunity, gave the mica men something—but something that neither they nor anybody else wanted—in the shape of a 35 per cent. *ad valorem* duty. This the Senate Committee has simply struck out, putting mica back on the free list.

Until eight or ten years ago stove manufacturers were

the chief consumers of mica, taking the greater portion of the product of the American mines, while no quantity worth mention was imported. The enormous growth of electrical manufactures during the past ten years has created a large demand for mica as an insulating material, and that demand is now chiefly supplied from India. The Indian mica has been found more suitable than the American for use in dynamos, because of its greater pliability, and the larger sized sheets obtainable from it; while it is less useful for stove doors, being clouded and more opaque. Under the electric demand the importation of Indian mica increased from a value of less than $1,000 in 1882 to $10,000 in 1883, and to $92,000 in 1889. From the figures given by the mica miners to the House Committee of Ways and Means, it appears that the American production has fallen off in value from $250,000 in 1882, $285,000 in 1883, $368,000 in 1884, to $161,000 in 1885, $70,000 in 1886 and $142,000 in 1887, while for 1888 and 1889 their estimates indicate a total of less than $100,000 for each year. During the past five years, it is alleged, mica has lessened in value 40 per cent. But assuming cheapness to be undesirable in mica—as Mr. Harrison assured us it was for coats and trousers—there is abundant evidence that the diminished quantity and lower price of the domestic production is mainly due to other causes than the importations from India. In consequence of the difficulty of getting an adequate supply of large sized sheets for stove doors (the chief commercial use of mica) and the dearness of such sheets, the stove makers divided their doors into a larger number of panels or panes, using two, four or more small sheets of mica in place of one large one. The difference in price per pound between small and large sheets is very great; prices given to the House Committee were 30 cents per pound for sheets 2″ x 2″ and $3.50 for sheets 6″ x 4″. Inasmuch as the Indian mica imported goes mostly to the electrical manufacturers, and but $92,000 worth was received in 1889, it is obvious that the mica miners are suffering less from foreign competition than from the effect of the business-like economy of the stove manufacturers.

PRESENT TENDENCIES IN DYNAMO AND MOTOR CONSTRUCTION.

The changes which have been brought about and are still going as a consequence of the introduction of the electric motor, afford a most interesting study, not only from the mechanical but from the social standpoint as well. The effect seen in the development of the steam engine alone would form an interesting chapter of history, leading to the irresistible conclusion that electric lighting and electric power have contributed more than any other influence to the perfection of the modern high speed engine. High speed was, indeed, necessitated by the construction of the dynamos and motors heretofore generally employed, in order, chiefly, to avoid as much as possible the use of counter-shafting. While the tendency to the reduction of speed in dynamos has made itself felt for some time past, it is but comparatively recently that this idea has gathered force with regard to electric motors. The reasons which have led to this new departure are, we think, not difficult to discern. It is, indeed, but the natural outcome of the endeavor to bring the speed of driver and driven shaft as nearly to uniformity as is possible, in order to avoid intermediate gearing, whether it be reducing or multiplying. The direction in which the tendency in question seems likely of accomplishment, practically, is in the employment of multipolar machines. The description which we give elsewhere of a motor designed to accomplish these objects shows that a very good slow speed machine has been made, so that the reproach, if such ever existed, that electric motor power meant high speeds, no longer holds true. What has just been said of electric motors applies equally well to the dynamo, the multipolar machine at reduced speed, such as that also illustrated on another page, finding a constantly increasing number of adherents.

The Western Union Fire.

Threatened more than once with a calamity of the kind, "195" succumbed to a big fire last Friday; and though the building was saved, the whole operating department, the battery room, and the Associated Press, were wiped out of existence. Fortunately no lives were lost. Had the fire broken out an hour or two later, the sadly inadequate means of access to the upper stories would have been responsible for wholesale slaughter. It is to be hoped that the damage done by the fire will cause many improvements to be carried out that have been delayed much too long. In the meantime, one cannot but congratulate the Western Union officials and the corps of operators on the energy and success with which they met the emergency and made the best of a very bad case. It was no common crisis, but it was faced with genuine courage, and matters were straightened out much sooner than one had any right to expect.

The New Unit "Henry."

Last week, the new unit "henry" was used for the first time, as a recognized addition to electrical nomenclature. Our readers will have noticed its appearance in the article by Mr. Steinmetz, and now Prof. Crocker extends us his congratulations upon this rapid passing into everyday use of the unit he has been urging for adoption. It will be recalled that at the Philadelphia conference in 1884, Mr. Preece had to make quite a vigorous fight for the "watt," and that one delegate, by way of complaint, deplored the early necessity of having to carry around a little pocket book, full of the names of the new units, as a remembrancer. But it cannot fairly be said that we have too many units. In reality more are wanted, and none will live unless they meet an actual necessity.

Electric Cabs.

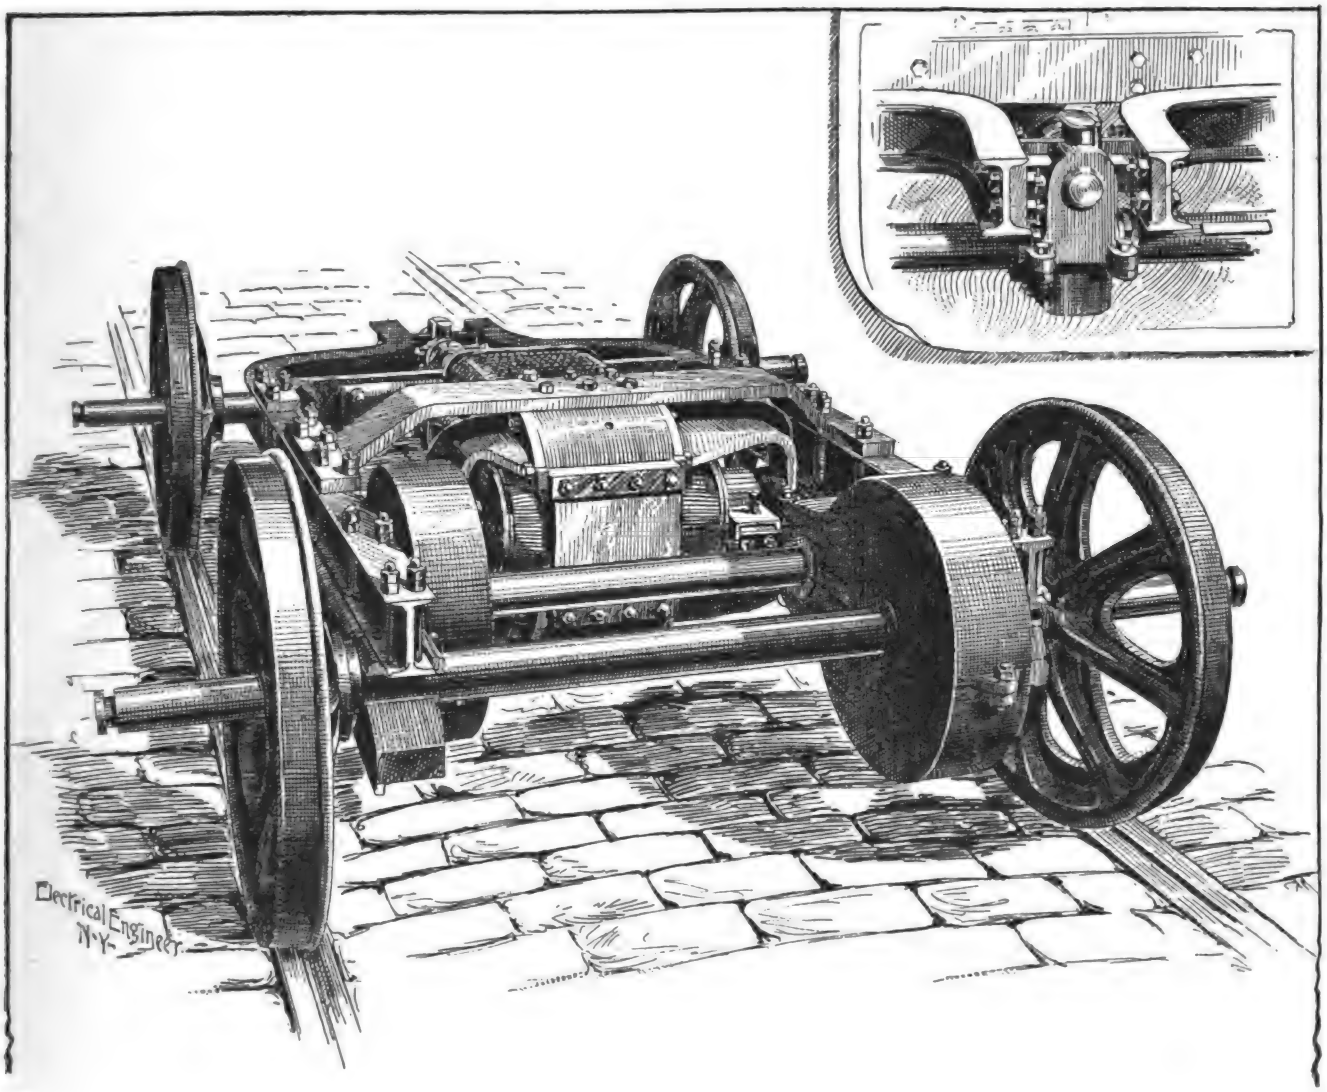
According to our Pittsburgh correspondent, the latest project there is an electric cab company, for which all the preliminary steps of organization have been taken. There seems to be more of politics than of practical science in the scheme, but no good reason can be found why electric cabs should not be run successfully where the streets are good. Our recollection of Pittsburgh is that its street paving is poor, not offering many opportunities for easy traction. However, the city is, it is said, to have no fewer than 40 electric cabs.

THE McDOUGALL ELECTRIC CAR.

For some time past Mr. W. M. McDougall, engineer of the McDougall Electric Company, of this city, has been at work on the construction of an electric street car, which is now rapidly nearing completion, and in which a number of novel ideas and improvements have been embodied by its designer, with the object of overcoming some of the difficulties heretofore met with in this class of work. The truck of the car, which is shown in the accompanying engraving, is provided with a motor of the single magnetic circuit type, the pole pieces, field cores and yoke being of mitis iron castings, and the armature of laminated sheet iron. There is no difficulty in obtaining an induction of 17,000 c. g. s. units per square centimetre in the field cores, when necessary, although the best induction for all-around economy is probably somewhat less.

The power is conveyed from the motor to one axle through a double spur gear transmission, the other axle not being used for propulsion. Mr. McDougall belongs to that school of engineers who contend that the only advantage of two motors under a car lies in the increased ability of the car to climb steep grades, while there is, he claims, a manifest disadvantage of the same nature as that encountered in hauling a train of cars with two steam locomotives hitched tandem. Again, gearing together rigidly the two axles of a street car, like the drivers of a steam locomotive, for the purpose of driving both from one motor, is, he claims, bad practice.

The motor car which is the subject of this article is intended for New York City, where experience has shown that one axle is sufficient for driving purposes. An inspection of the accompanying illustrations will show clearly that the McDougall motor suspension, while maintaining a perfect alignment between the armatur eshaft, counter-shaft and driving axle, in no way interferes with the flexibility of the running gear of the car. The motor is suspended by two bridges from two I beams of wrought iron. On the under side of these beams are a pair of combination boxes in which the counter-shaft and driving-axle revolve, thus maintaining the alignment and distances between centres, but allowing a slight end play. The other ends of the I beams are bent toward each other and bolted to a bronze casting, which forms one part of a universal joint; the other part of the joint, also of bronze, embraces the other axle, as shown in the vignette.



The McDougall Electric Car Truck.

This universal joint, besides the usual rotary motions, has an indefinite end play on the axle and a smaller end play on the longitudinal pin, so that the car gear has the requisite elements of flexibility, namely, a slight variability of wheel base, a perfectly independent and ample end play of axles, and a perfect freedom of the axles to depart from parallelism by motion in vertical planes. The yoke end of the motor is hinged to the bridge, so that the armature end may be swung down for removal when necessary. On the other hand, if it becomes necessary to change a field coil the yoke may be removed without disturbing the armature end. All bearings are self lubricating, and, it is calculated,

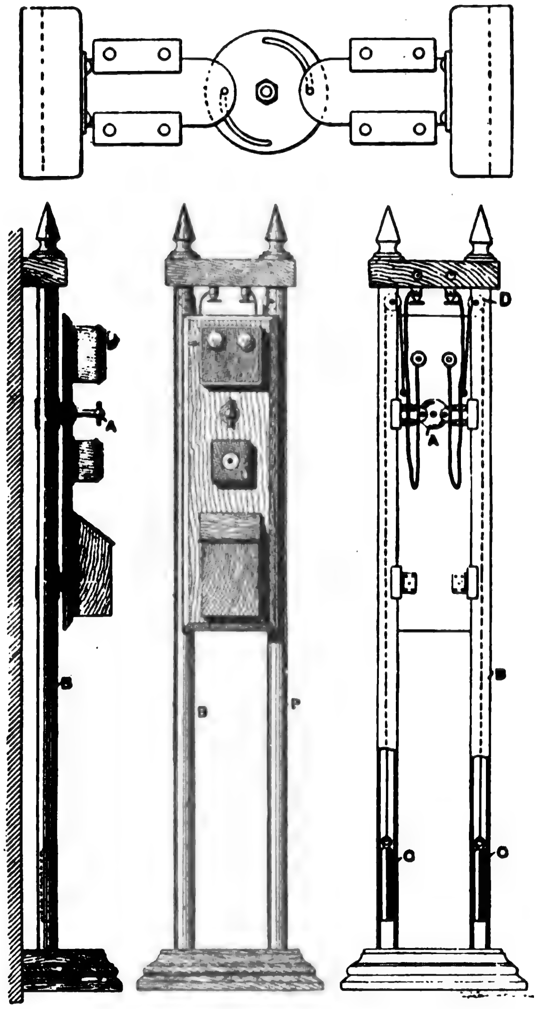
will require no more care than the ordinary street car journals.

The gears are incased in easily removable shells, which retain the lubricant and exclude the grit that so quickly ruins exposed gears.

The present car is built for storage batteries, but the McDougall Electric Company intend to build cars for the overhead system also, besides motors for stationary work. Mr. McDougall, we may add, has protected his suspension by patents, and the car will soon be put in practical operation in this city.

AN ADJUSTABLE TELEPHONE TRANSMITTER.[1]

A METHOD has recently been devised by Mr. J. C. Goulding, of Cardiff, for adapting telephone transmitters to the varying statures of the people who use them. The invention consists essentially in giving the connecting wires a considerable amount of play, and in mounting the transmitter, bell and battery upon a carriage which can travel vertically up and down upon guides. If desired, the range of motion may be made so great that the user may sit down during a lengthened communication; or, even further, the



FIGS. 1, 2, 3 AND 4.—ADJUSTABLE TELEPHONE TRANSMITTER.

guides might be made the whole height of the building, so that the telephone could be used by the occupants of the various floors. The arrangement of the apparatus will be easily understood by reference to the accompanying illustration, Fig. 1. The carriage which carries the transmitter is balanced by the weights, C, which are connected to cords; these cords pass down the hollow standards, B, and over the pulleys, D. The carriage may be clamped to the standards by means of the handle, A. Fig. 2 shows an enlarged view of the clamp. This apparatus is being made by Messrs. Woodhouse & Rawson, of London.

1. *Industries.*

BULL'S MAGNETIC BOILER INCRUSTATION PREVENTER.

IN a recent paper read by Mr. W. B. Bull, of Quincy, Ill., before the American Waterworks Association, he described the results of a series of experiments to obtain a method of overcoming scale in boilers by the use of magnetism. After trying various devices he finally adopted one in which the magnets are arranged within a cylinder in sheets and bundles. The latter form is shown in the accompanying engravings, Figs. 1 and 2. Here the magnets,

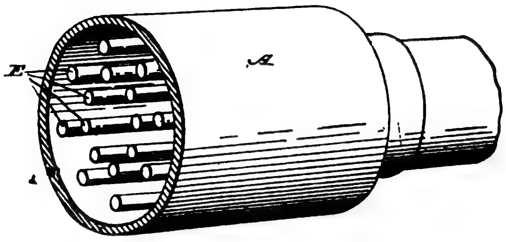


FIG. 1.—MAGNETIC BOILER INCRUSTATION PREVENTER.

E, are cylindrical in cross-section, and are so arranged that but very small spaces are left between any two magnetic points, the collective area or capacity, however, being made equal to, or greater than, that of the conduit on either side of the magnets, to prevent any retardation or permit the water to remain longer within the magnetic field. The cylindrical sheaf of magnets, it will be seen, is held in place by an open frame-work, E′, of non-magnetic material,

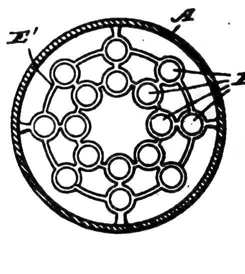

FIG. 2.—MAGNETIC BOILER INCRUSTATION PREVENTER.

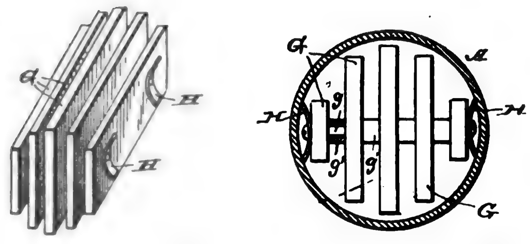
and the whole sheaf and frames are so joined as that they may be readily removed in a body from the conduit.

A more economical and perhaps more convenient form of the device is illustrated in Figs. 3 and 4, wherein a series of prismatic magnets, G, is provided, joined together by bolts and intermediate washers, *g g′*. The magnets are properly proportioned and arranged, with the widest at the middle and gradually narrowing as they near the sides to fit within a tubular conduit or chamber, leaving a series of



FIGS. 3 AND 4.—MAGNETIC BOILER INCRUSTATION PREVENTER.

slits or flat openings for the passage of the water. This form of the sheaf or bundle of magnets is held in place by arms, H, secured in place by the bolts and resting against the sides of the conduit.

The magnets are made of plate bars of hard steel. In a cylinder 10 inches in diameter there are about 150 magnets made of ¼-inch steel, 1 inch in width, and of lengths varying from ¾ to 2¼ inches.

Mr. Bull also proposes to employ the same arrangement for the artificial "ageing" of liquors.

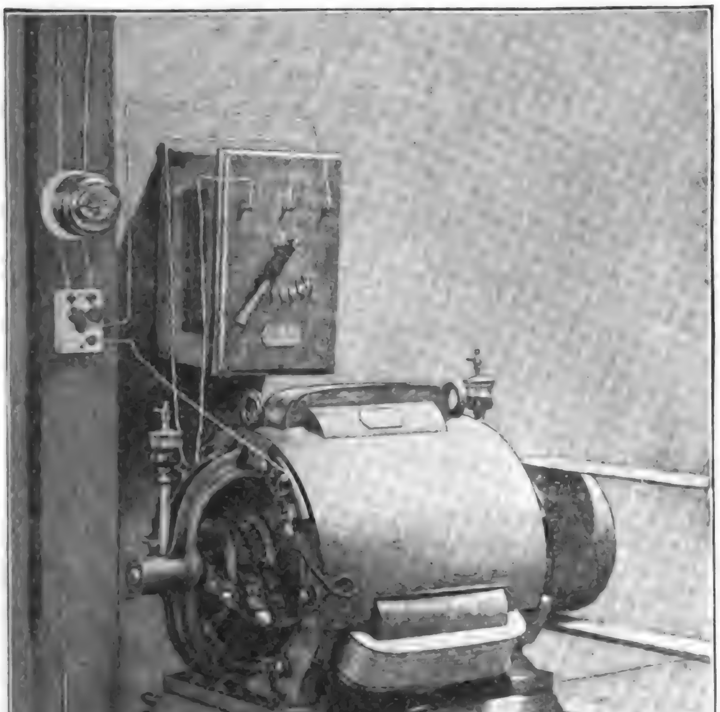
THE NEW PERRET SLOW SPEED MOTORS.

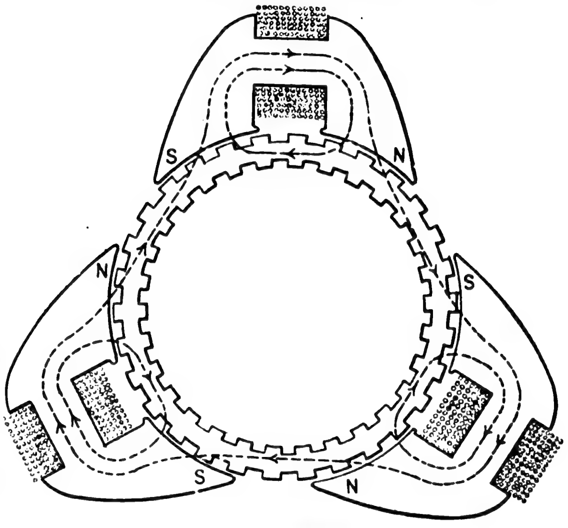
We bring to the notice of our readers, on this page, a departure in motor construction which has been effected by the Elektron Manufacturing Co., of Brooklyn, being the work of Mr. Frank A. Perret, the electrician of the company.

The new machines were brought out last year and have been giving great satisfaction wherever introduced, but a detailed description has not before been published, as it was desired first to test them thoroughly in actual work and to secure patents, which has now been done.

The new machines differ from the well known two-pole Perret motors in that they are of the multipolar type. This form has been adopted for all sizes above 2 h. p., and the company are now regularly manufacturing machines of 4, 6, 8, 10, 15 and 20 h. p., wound for 220 volts; and they are wound to order for any E. M. F. between 100 and 500 volts.

These machines mark a noteworthy advance in motor and dynamo construction, as they combine in one machine the important features of high efficiency, extremely low speed and close regulation without excessive weight and bulk. It is found in the electric motor field, as elsewhere,





Figs. 1, 2 and 3.—Perret Slow Speed Electric Motors.

that each make has its peculiarities; one excelling in this feature, another in that, and the manufacturers question if any one machine has ever before been put on the market which excelled in all of the three features mentioned. It is well known that most motors and dynamos are run at a high rate of speed, because the efficiency, regulation and output now demanded cannot be obtained at a low speed with the ordinary construction.

In the opinion of many of the best electrical and mechanical engineers this high speed is objectionable on various grounds, and not a few have during the past year recorded their belief that the next great advance would be in the line of a large reduction in speed. This belief has long been held by Mr. Perret, who has now carried it out in actual practice. That the improvement made by him is a radical one, is apparent from the simple statement that the revolutions of armature per minute in the ordinary shunt-wound Perret motors of the new type are between 500 and 600 in the sizes ranging from 4 to 20 h. p., which is less than half the usual speed, and for special work they may be wound to run at 350 revolutions or even less. It is of course understood that motors have been built that ran nearly as slow, but they were made expressly for some special work and were comparatively heavy, bulky and costly considering their power. It is thus a very different matter to put the low speed machines on the market at the same price as ordinary high speed.

It is not as fully understood by the general public as by builders and electricians that reducing the speed of a dynamo electric machine reduces the power or output accordingly, and that increasing the speed increases it. For example, a certain Perret motor, running at 600 revolutions per minute, develops 4 h. p. If it were wound suitably and run at 1,200 revolutions per minute, it would develop 8 h. p., and the price for an 8 h. p. machine could be obtained. In order to furnish a motor to develop 4 h. p. with the same speed as the Perret (600 revolutions), it would be necessary to use a machine which is now rated at 8 or 10 h. p. and which would either have to bring the price of an 8 h. p. machine or involve a loss.

The Elektron Manufacturing Co., therefore, claim that

in comparing prices, buyers should compare speeds also. The practical advantages of low speed machines are many. For instance, in ordinary machine shops, wood-working shops, printing offices, etc., the shafting is commonly run at 200 to 300 revolutions per minute, and it is a simple matter to belt direct to it from a motor running 500 to 600 revolutions, thus saving the first cost of a counter-shaft and one belt, and saving considerable power which would be lost in transmitting through the counter-shaft and additional belt used necessarily with a motor running at 1,000 to 1,500 revolutions. The same applies in the case of an elevator operated by belt; and in elevator work, indeed, it is possible to gear directly from the motor. The Perret machines have recently been applied by direct gearing to pumps and to coal-cutting machines in mines; also to the operation of coal-cutting machines by means of rope belt transmission from the motor to the cutter, and the company now have some very large orders for this class of work, which they claim would have been very difficult to meet with motors of high speed.

In addition to the advantages of low speed in the special cases mentioned, there is, of course, in all cases a general advantage in the avoidance of the rapid wear and deterioration usually connected with high speed. The machines are built with a 6-pole field and with armatures of large diameter, thus securing a powerful torque and great momentum of armature, which is a decided advantage when a heavy load is thrown on suddenly, as is often the case in elevator work and all kinds of hoisting.

It is quite remarkable that Mr. Perret has been able to retain in these larger machines the distinctive feature of laminated field magnets, for which his smaller machines are noted, and, indeed, the results secured would be well nigh impossible with any other construction.

In the accompanying illustrations Fig. 1 is a side view of a 20 h. p. motor complete with sliding base and starting-box. Fig. 2 is an end view of the same, and Fig. 3 is a diagram showing a cross section of the magnetic circuit.

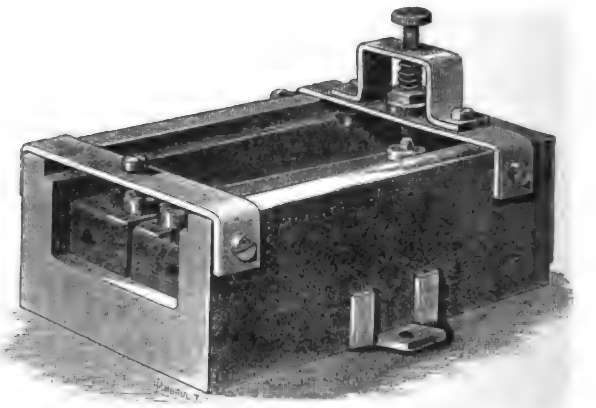
It will be seen that the armature is a ring of comparatively large diameter, with longitudinal channels on its periphery, in which the conductors are wound and thus embedded in the iron, which is in such close proximity to the iron pole-pieces that there is practically no gap in the magnetic circuit. The field consists of three separate magnets arranged at equal distances around the armature, each magnet having two pole pieces. The winding is such as to produce alternate north and south poles. The magnets are built up of plates of soft charcoal iron, which are shaped as shown in the diagram, and the magnet thus produced is of such form that it may be readily wound in a lathe. A non-magnetic bolt passes through a hole in each pole-piece, and the plates are clamped together between washers and nuts. These bolts also serve to attach the magnets to the two iron end frames, which are ring-shaped and are bolted to the bed plate of the machine.

The magnetic circuit is of unusually low resistance, by reason of its shape and shortness, which is shown by the diagram, and the superior quality of iron used. There is no magnetism whatever in the frame-bed or shaft of the machine, as the magnets are supported at some distance from the frame by means of the non-magnetic bolts, and the armature is mounted on the shaft by spiders of non-magnetic metal. There is, therefore, no opportunity for magnetic leakage, and, furthermore, the whole is enclosed by a shield or case of sheet metal as shown in Fig. 1. With such a construction it is not strange that the motors have won their reputation for high efficiency and close regulation as well as low speed.

The machines are calculated to be equally as efficient and desirable as dynamos, and are coming into use rapidly in small isolated incandescent light plants. For this purpose they are compound wound, and the regulation is so perfect that all but one lamp may be suddenly turned off without moving rheostat or brushes, and without noticeable change in the brilliancy of the remaining lamp. This severe test has been made repeatedly in the presence of electrical experts. Their low speed makes them well suited for direct connection to steam or gas engines, and they are specially adapted for lighting railway trains, yachts, steamboats, etc.

AN EXCESS CURRENT DETECTOR.[1]

In using secondary batteries it is well known that too heavy a rate of discharge may permanently damage the cells, and it is, therefore, important to have some method of calling the attention of the attendant when the current exceeds a certain value. With this object in view the Electrical Engineering Corporation, Limited, have produced the device which we illustrate on the present page, and may be described as follows: The body of the instrument is of slate, on which is mounted a V-shaped compound strip, composed of two metals soldered together in the same way as the strips used in Breguet's metallic thermometers and in certain forms of compensating pendulums. The current from the cells passes down one leg of



Excess Current Indicator.

the V and up the other, and, of course, heats up the compound strip; which, owing to the unequal expansion of its two metals, coils upwards, until, on the current reaching a certain value, its free end completes the circuit of an electric bell, thus warning the attendant that the current has become excessive. The device is ingenious and so simple that it would seem practically impossible for it to get out of order.

AN EASY RULE FOR CALCULATING APPROXIMATELY THE SELF-INDUCTION OF A COIL.

In a paper recently communicated to the Physical Society, Prof. John Perry gives a rule for calculating approximately the self induction which relates to hollow cylindrical coils, and is expressed by the following formula:—

$$\text{L (in secohms)} = \frac{n^2 a^2 \div 10^7}{1.844a + 3.1c + 3.5b}$$

where n = number of windings,
a = mean radius of winding in centimetres,
b = axial length,
c = radial depth of winding,

and b and c are less than $\frac{a}{2}$.

The time-constant of such a coil is given in terms of the volume of copper (V^1) in cubic centimetres by

$$\frac{L}{R} = \frac{V^1 \div 1{,}000}{728a + 1.33c + 1.5b},$$

and the conditions for making this small are pointed out in the paper.

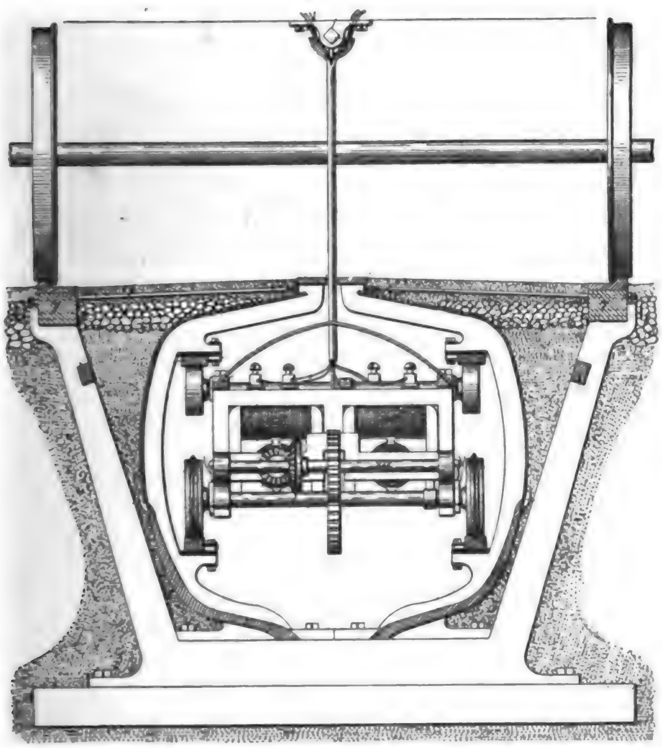
ACCUMULATORS WITH POROUS PARTITIONS.

In connection with M. Reynier's latest form of storage cell,[1] M. Chatiliez, manager of the Verdun water power electrical station, writes to *L'Electricien* to say that he has met with considerable success by employing ordinary porous partitions between the battery plates. These partitions are fluted to admit of the introduction of the electrolyte and pierced with holes to allow the liquid to circulate, and to diminish the internal resistance. The end plates rest against india-rubber washers. M. Chatiliez states that a series of experiments with these plates have shown that the grids may be made lighter and the perforations larger than usual without detriment. The internal resistance of the cells may be kept within moderate limits by slightly increasing the density of the solution.

McLAUGHLIN'S ELECTRIC RAILWAY CONDUIT SYSTEM.

Up to the present time electrical engineers have expended not a little time and ingenuity in methods for attaching the electric motor to the car truck, and in its connection to the driving axle, and have considered the



McLaughlin Electric Railway Conduit.

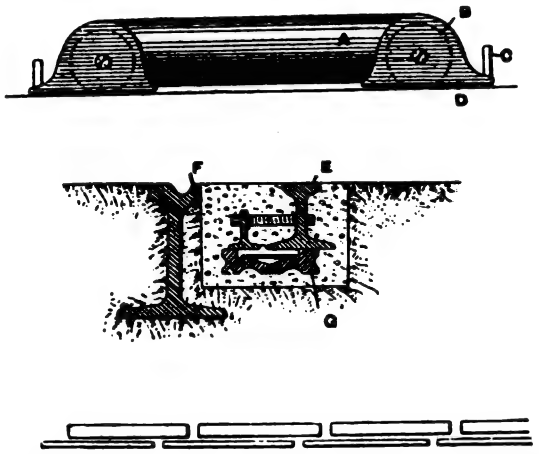
conduit method of conduction as a separate problem. It seems, however, that the field in this direction is by no means exhausted, as is evidenced by a system of electric railway operation and construction recently designed by Mr. James F. McLaughlin, of Philadelphia. It has just been patented. Broadly speaking, Mr. McLaughlin's system is one in which the electric motor itself travels within the conduit and is mechanically connected to the car which it drives on the surface, as distinguished from the motor carried by the car to be propelled.

The manner in which this idea is carried out is shown in the accompanying engraving. As will be seen, there is provided a conduit having two pairs of conductors, each of which constitutes tracks on which travel the wheels of a truck containing the electric motors, and these wheels are so arranged that they are forced into strong frictional contact with the conductor-tracks, so that good traction is obtained as well as good electrical contact. This motor-truck is connected with the surface-car to be driven by an arm extending upward through the slot usually provided in underground conduits for electric railways, and conductors connected to the motors are also carried to the car to be driven and connected to the switch under control of the driver. The motor-truck is also so connected to the car to be driven that the weight of the car is in a measure borne by the motor-truck, and the traction of the latter on the conductor-tracks is thereby increased, while provision is made for the slight vertical vibrations of the car to be driven when in motion.

THE LINEFF ELECTRICAL TRAMWAY.[1]

Some two and a half years ago a public trial of the Lineff Electrical Tramway was made at the depot of the West Metropolitan Tramway Company at Chiswick.

About eighty yards of line were laid, and a further portion, with turn-outs, was then being constructed. The system consisted of a conductor, well insulated throughout a large proportion of its length, mounted on brackets or chairs in a concrete conduit. At intervals of 3ft. 6in. iron crutches were provided as contact pieces, and a slack wire rope suspended beneath the car touched, and was dragged over, two or three of the crutches at a time. The attachments for the collecting rope passed through a slot in the roadway. For a low-pressure slot system the arrangement was excellent. The presence of the slot, however, was considered by the vestry authorities to be so objectionable that, as far as we are aware, the system was



Figs. 1, 2 and 3.—The Lineff Electric Railway System.

never put to practical use. Mr. Lineff has, therefore, worked out a new system, avoiding the use of the slot. He places his conductor in a conduit closed mechanically, but accessible, magnetically, through an iron covering. The conductor is laid in a small conduit, and contact is made by lifting a loose iron strip against the top of the conduit by means of a passing magnet. The magnet, A, Fig. 1, is provided at either end with a cast-iron wheel, B, making both electrical and magnetic contact with a smooth rail, laid in sections 3ft. long. The magnetic circuit is assisted by shoes, D, on each side of the wheels, having a clearance of about $\frac{1}{8}$in. from the rail.

Mr. Lineff provides a vertical brush, C, on the outer shoe at each end, to assist in collecting the current, as the iron wheels are of so small diameter that they would hardly make a contact of sufficient area with the rail.

The conduit is shown in section in Fig. 2, together with one of the tram rails. The I contact rail, E, in 3ft. lengths, is shown flush with the roadway. A smaller ⊥ rail, entirely buried beneath the surface, is mechanically and electrically connected to the I rail by yellow metal bolts, which insulate it magnetically. The lower flanges are

1. The Electrical Engineer, July 9, page 51.

1. *Industries.*

flush, and form the top of the conduit, which is constructed of asphalt, with earthenware insulators, one of which is shown at G, in section, in Fig. 2. Bare copper conductors are laid in two grooves in the insulator, and upon them lies a strip of galvanized sheet iron, about ⅛in. thick and 2¼in. wide. Both the conductors and the strip are shown black in Fig. 2. The whole is imbedded in a block of asphalt.

When the magnet which is carried underneath the car induces magnetism in the iron rails, a portion of the galvanized iron strip is picked up through a distance of about $\frac{5}{16}$in., and is held against the flanges of the rails, thus putting them in connection with the conductors. A passage is thus afforded to the current from the conductors, through the wheels on the magnet to the motor, and thence, as in most electrical tramways, through the car wheels, to the tram rails, and, to a certain extent, to the earth.

The magnet is said to require only 60 watts to hold up the iron strip, but 100 watts are employed in practice. The holding up of the strip does not strictly need any expenditure of power, but merely a certain number of ampere turns, involving a waste of power on the resistance of the copper exciting coils.

With a simple row of I rails, it was found, in preliminary experiments, that a very considerable excitation of the magnet was required, probably on account of end leakage. The introduction of the second, the buried rail, has overcome this difficulty, and in an ingenious way. The rails are arranged as shown in plan in Fig. 3, breaking joint with each other. The space between their flanges is small, and the area of the edges of the flanges opposed to each other is considerable. An easy path is afforded to the magnetic flux, zigzagging from one rail to the other. The inventor describes this as a number of magnetic stitches. The moving magnet undoubtedly does its work, and the car was handled with ease, and ran with no apparent sparking. A battery of some kind must be carried, in case a momentary break of the circuit were to allow the iron strip to drop. A hinged board is provided at either end, and on meeting an obstacle it yields and reverses the motor, at the same time setting the resistances to give a slow speed. An Immisch motor and Renold chain are used. A cleansing rubber keeps the contact rails clean, as any small stones would have a disastrous effect on the shoes, with their small clearance. As in the Wynne magnetic system, only those sections of the contact rail which are beneath the car form a part of the electric circuit, and are therefore out of reach.

THE NEW WENSTROM DYNAMO.

In a recent issue,[1] we illustrated diagrammatically the new Wenstrom dynamo, and we now take pleasure in showing the machine as it is built to-day, in perspective.

This machine is of the "iron-clad" type, and is shown in two views in the accompanying engravings, Figs. 1 and 2.

In general design it consists essentially of a cylindrical shaped body of cast iron, closed with heads or ends of the same material, and the whole, together with the bearings for the armature, resting on a bed-plate, forming a compact, easily constructed and simple piece of mechanism.

The armature, which is illustrated in Fig. 3, is so constructed that the iron of the armature comes as close to that of the field magnets as is permissible for free running. This is accomplished by threading the armature conductors through the iron a short distance below the periphery of the armature. In this way the resistance of the magnetic circuit is reduced to a minimum, the air space being almost entirely overcome, so that the current required to magnetize the field is correspondingly reduced. Again, the insertion of the wires within the iron completely protects them from injury during transportation and from all rough usage; and it also prevents their shifting during the operation of the machine, which sometimes leads to short circuits and consequent burn-outs. On account of the intense field possible by the reduction of the air gap the Wenstrom machines generate the required E. M. F. at a reduced peripheral speed.

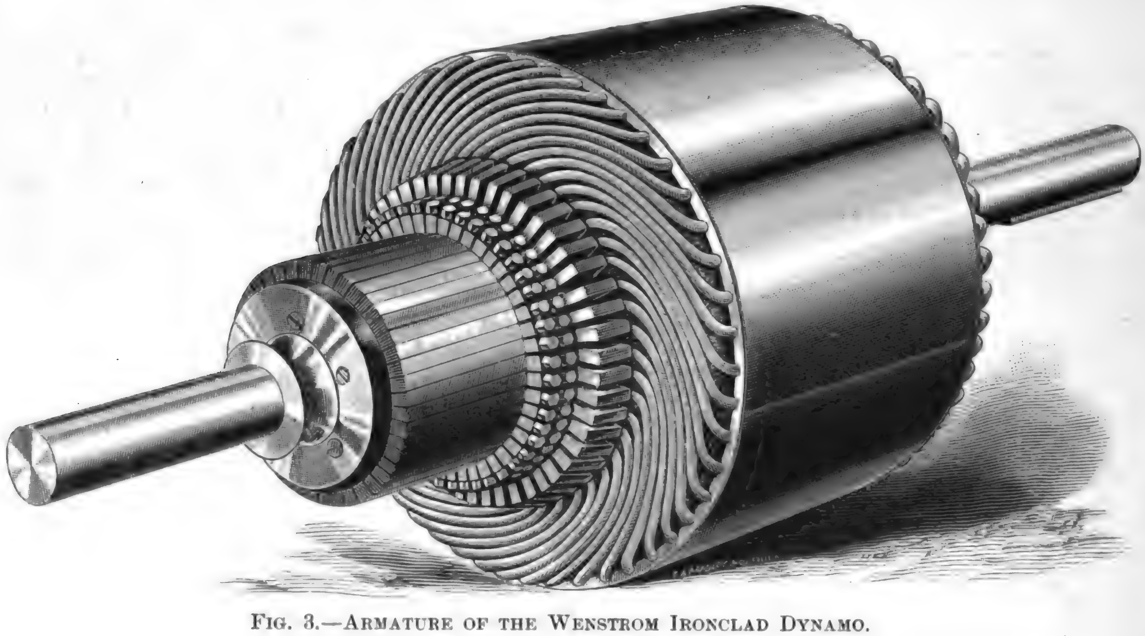


FIG. 3.—ARMATURE OF THE WENSTROM IRONCLAD DYNAMO.

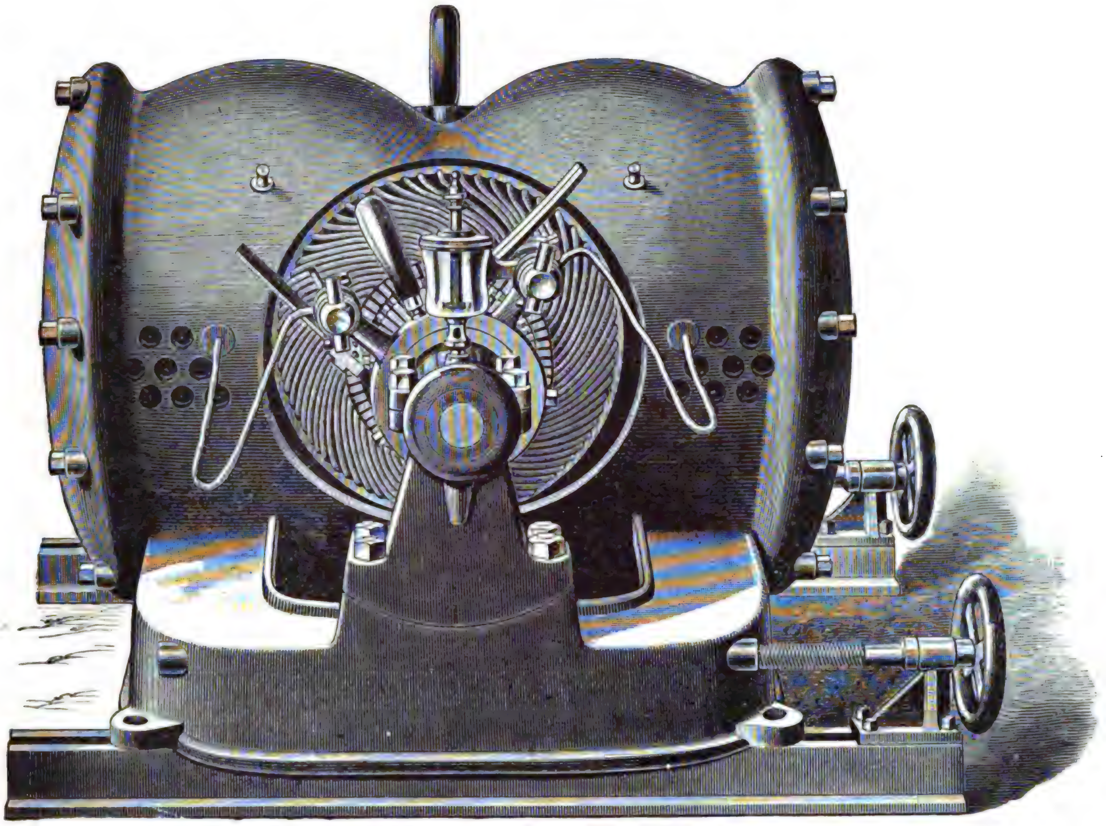
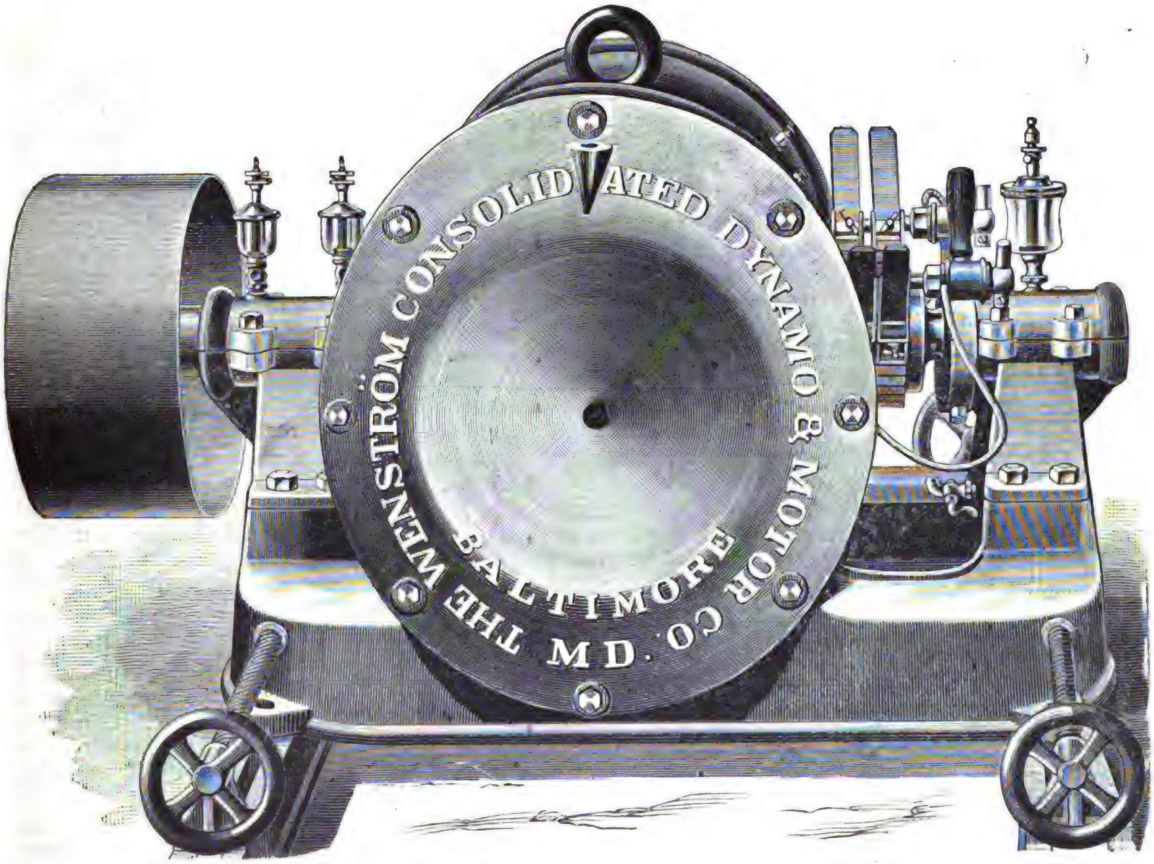
The motors manufactured by the company are of the same general design as the machine described above. They range in power from ½ to 100 h. p., and as they revolve at low speeds it obviates the use of considerable counter-shafting.

1. ELECTRICAL ENGINEER, June 11, 1890, page 455.

TESTING THE SIMS-EDISON TORPEDO.

A party of excursionists went to Willett's point, near this city, on July 15, to witness a trial of the Sims-Edison electric torpedo. Beside Mr. Warner Miller, there were present Everett Frazer, president of the Sims-Edison Electric Torpedo Company; W. Scott Sims, joint inventor of the torpedo; Capt. Ambrose Snow, Henry W. Munroe and Warren E. Hill. The torpedo, appropriately called a fish-torpedo from its shape, was started from a point about 200 yards from the dock, and ran in an almost circular course, at an estimated rate of 20 miles per hour. The charge consists of about 250 lbs. of dynamite. The company is now building for the government a larger torpedo, capable of carrying two miles of wire and 450 pounds of dynamite. The diameter of the boat will be 25 inches, and the length 33 feet.





FIGS. 1 AND 2.—THE WENSTROM IRON CLAD DYNAMO.

SHIP LIGHTING BY ELECTRICITY.—I.

BY W. H. FLEMING.

EIGHT years ago I crossed the Atlantic on a large and powerful mail boat, and what was considered a first-class, comfortable steamer. The saloons were then lighted by means of oil lamps, giving a poor light compared to what oil lamps can even now develop. The state rooms were lighted by candles, one candle placed in a receptacle in the division of each two rooms, so that it should do its duty of illuminating, as far as possible, both cabins; at 11 P. M. all lights were put out, and a solitary smoky lamp was hung up in the saloon to act as a night light.

Shortly after the introduction of lighting by electricity was proved to be not only feasible but practicable, an impetus was at once given to the lighting of steamers. The first transatlantic steamer to be thus lighted was the City of Berlin, of the Inman Steamship Company, but this was used only for the engine room and illuminating of the main saloon, and arc lamps were employed of the Siemens type. From that date forward, the progress of ship lighting by electricity has been marked and rapid, and to day, few steamers of any size, either passenger or freight boats, leave the builders' yards without a complete electric light plant installed on board.

The installations vary in capacity according to the passenger accomodations and the size of the steamer, from 50 lamps, to such as those installed on the City of Paris, and her sister ship, of 1,200 16 c. p. lamps. Great artistic skill has been displayed in the introduction of the electric fittings on board these magnificent Atlantic liners, and it is indeed a wonderful sight at night when afloat on one of these steamers, lighted from stem to stern and from engine room to pilot house. Since the dynamos are kept running continuously during the voyage, advantage has been taken of running motors for various purposes—fans for ventilating and cooling the state rooms and lower decks, motors for hoisting the ashes from the stoke-holes, and for many other purposes where they can be usefully and economically employed.

The Board of Trade have recently sanctioned the use of electric lights for the side lights and head lights. Two lamps, usually of 50 c. p. each, are placed in the lanterns formerly containing the oil lamps, and provided with automatic cut-outs, so that in the event of one incandescent lamp being extinguished, the other is immediately lighted. During the past summer, search lights of high candle-power have been installed on many large steamers, the object of these lamps being to detect ice and other obstacles during foggy or dark nights. They have proved of considerable use in lessening the dangers of ocean travel. Search lights is also employed in picking out buoys or entering channels or harbors at night time. It is only within the last two years that steamers have been permitted to navigate the Suez Canal after sundown. This is now accomplished by the aid of a powerful search light placed on a platform especially rigged for the purpose in front of the bows of the vessel, and about five feet above the water line. The whole outfit, including engine, dynamo, cable and lamps, is taken on at either Port Said or Suez, the two entrances to the canal, and after being used for this especial night travel are sent ashore. The charge for the use of this apparatus is moderate, and repays the owner of the vessel for the use of it, as the ship can then complete her voyage through the canal well within 24 hours.

The writer well remembers a passage through the canal occupying three days, though the distance is only 88 miles, owing to delays, and the then crowded condition of the canal. Vessels are not allowed to move at a higher rate of speed than five miles an hour, on account of the small width of the canal, and the wash of waves that otherwise would be caused by a vessel proceeding at a higher rate of speed, causing damage to the banks.

To ask any one even familiar with electric lighting on steamers, the number of incandescent lights that are burning every night on the north Atlantic, their answer would be considerably below the actual number. The total average number at the present time of 16 c. p. lamps lighted on this great fleet of ocean steamers numbers 100,000. This means machinery required to drive the dynamos of 10,000 h. p., and, taking a low average of six hours per day, when their full number of lights are on, requires a consumption of over 200 tons of coal per day, which would compare on land with a central lighting station of the first magnitude.

In many of the large ocean steamers duplicate sets of dynamos and engines are installed, to guard, as far as possible, against a total breakdown. To the engineer in charge, the adoption of electricity on board has proved of great service; any one who has had experience in examining the interior of the cylinders of boilers, will at once appreciate the advantage of a portable electric lamp over that of the ordinary "duck lamp," with its attendant smoke, smell, and its ready aptness to go out just at a critical moment of examining some particular seam or joint. Incandescent lamps, when protected with some suitable water-tight receptacles, have been used by divers for examining the propeller blades and stern post, and have thus saved the expense of docking the ship.

The prices at which installations can be placed vary considerably with the amount wished by the owners to be expended on the fittings. For the sake of an example it may be stated that a 100 light plant, including engine and dynamo, coupled direct, and supplied with the usual reading instruments, and wires run in molding, with all necessary cut-outs and switches, will cost, including lamps and sockets, but no fixtures, the sum of $2,700. This figure does not include steam and exhaust piping; the steam piping is taken not only from the main boilers, but the auxiliary or donkey boiler, so that the electric plant can be operated while the vessel is lying at her dock discharging and taking cargo.

The space occupied by this size of plant will be ten by three feet. The important points in the construction of the ship dynamo are as follows:

1. It should be direct driven. The reasons are obvious, as not only is the space taken up by the belting valuable, but in a sea-way the danger of running belts must be considered, and the possibility of accidents must be reduced to a minimum; it should be compact.

2. It should be free from liability to injury by salt water, and not too subject to mechanical damage.

On board ship salt water and damp air get everywhere, and within the last year a number of cases of slight burnout have occurred in armatures, which, when installed, measured high in the hundreds of thousands of ohms insulation. The dynamo should not be easily harmed. The dynamo room is now always low down in the ship, and when the light is not in use the room is very dark, rendering careful inspection difficult.

3. The dynamo should have small effect upon the compasses. This point has received little attention, though it is a matter of great importance, as the effect on many vessels is so large that, in order to work up the day's run, it is necessary to know the hours during which the dynamos have been in operation. Complete deviation tables are therefore necessary for the two cases. In different types of dynamos the effect with a twenty horse-power machine, at a distance of twelve feet, will vary from less than one-twentieth of the horizontal component of the earth's magnetism to several times the strength of the horizontal component. The latter is, unfortunately, rather the rule than the exception, and, in consequence, the position of the dynamo room has to be well borne in mind in locating the standard compass.

4. It should be easy in running and require but little attention. The machine should be non-sparking under constant load and also be able to stand sudden large changes of load with little sparking. This is necessitated by the

fact that the dynamos now supplied for incandescent lighting are also used for search light work, and the conditions are aggravated by most of the search lights having hand regulation only. Thus, with a 200 ampere machine, not only are from 50 to 100 amperes thrown suddenly on and off, but, at the moment that the operator at the projector brings the carbons together, the dynamo is suddenly called upon to deliver over three-fourths of its total capacity.

5. It should be efficient and run cool, the former in order to avoid the waste of energy and a corresponding amount of coal supply, and also in order to avoid over-heating. The dynamo rooms on ship board are, at best, warm, notwithstanding the motor fans, which are now usually supplied, and thus the safe limit of extra heating is reduced. At the same time consideration for the attendants requires that the cramped space be kept as cool as possible.

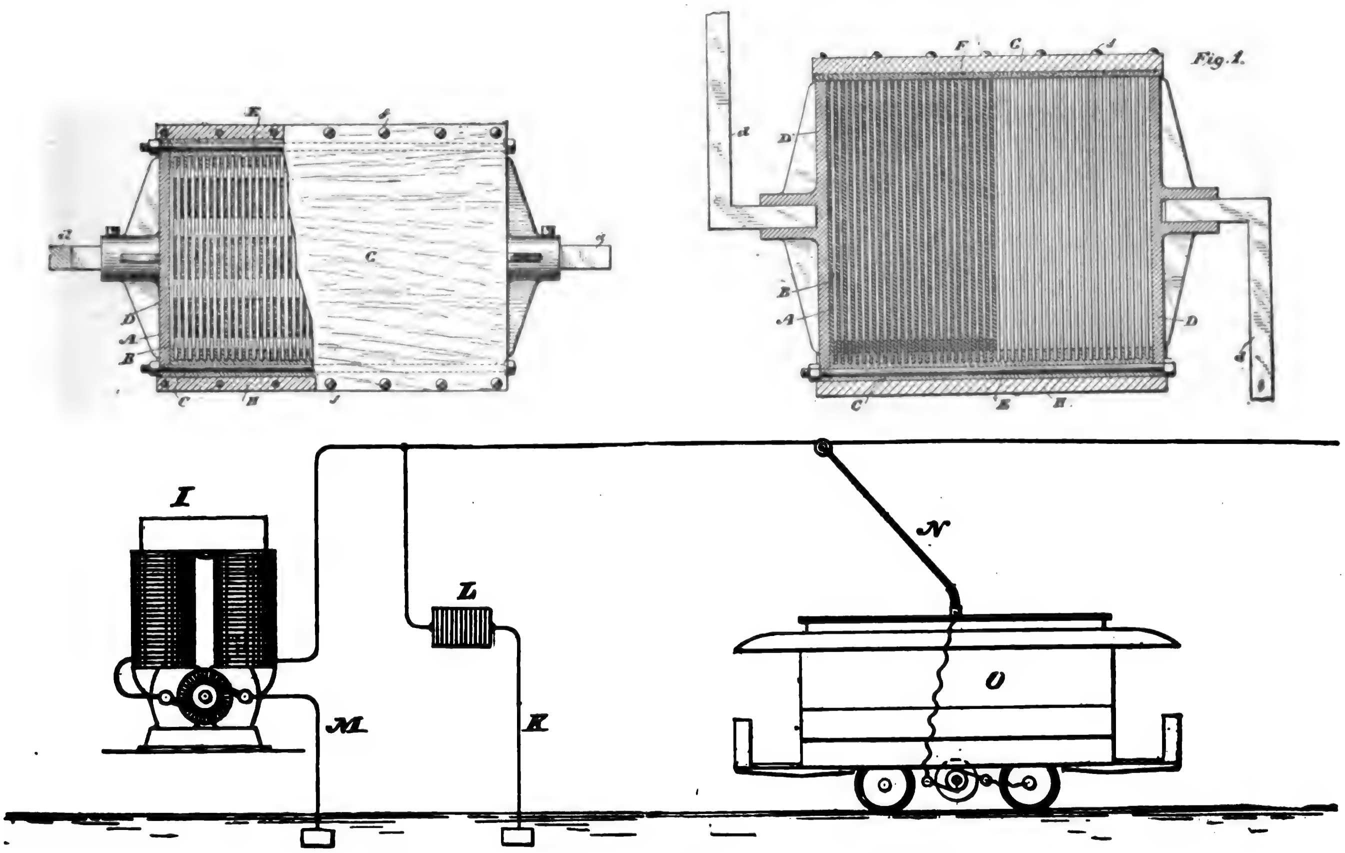
6. The dynamo should maintain a constant potential at all loads. This is, of course, accomplished by employing a compound-wound machine.

It is customary, where installations exceed three hundred lights, for the steamer to carry an extra man, rated as the electrician or junior engineer, whose duties are to take charge of the dynamos while they are running, and also to make such repairs as may be required from time to time. It is important, I think, to the owners, that the men so employed should in future, before having handed over to their care machinery of considerable value, be required to pass some examination, giving proof of their technical knowledge, the same as the men who are in charge of the main engines, and who are required to hold certain certificates. In many instances, had this rule been adopted, money would have been saved, as accidents have happened through sheer ignorance. I have known a case where the armature bearings have been allowed to heat, and instead of taking proper precaution to avoid or remedy this, a stream of water from a hose has been played on the bearings; in this particular instance the wiring of the ship was what is known as the single wire, or ship return. I leave it to the reader to imagine the result.

THE HOLCOMBE LIGHTNING PROTECTOR.

It was not long after electric lighting and power distribution had come into use that it was recognized that the methods employed to protect circuits from lightning, and which had, up to that time, been modeled upon those employed in the telegraph service, were inadequate. Damage from lightning was of frequent occurrence. It was clear that the introduction into the circuit of an apparatus which contained electro-magnetic coils created a self-induction which opposed more or less the passage of the lightning discharge and thus introduced an objectionable feature.

Various attempts have, therefore, been made to provide a lightning protector which should have no inductive resistance. The most recent work in this direction is embodied in the lightning protector designed by Mr. A. G. Holcombe, of Long Island City, N. Y., in which the object aimed at is to obtain a lightning protector, which, while always remaining in circuit and directly connected to



Figs. 1, 2 and 4.—The Holcombe Lightning Protector.

ground, shall have practically no resistance, and shall introduce no self-induction to oppose the passage of the discharge.

The anomalous statement that the arrester is permanently connected to the circuit and to the ground, and is practically of no resistance, may appear somewhat strange, but the manner in which Mr. Holcombe has effected this will be conceded to be highly ingenious. The principle embodied in the protector, briefly stated, consists in employing an apparatus having a potential of its own, equivalent to that of the line to be protected, and connected to the line in opposition, so that normally no current can pass through the protector.

This is carried out in practice in the apparatus shown in the accompanying illustrations, Figs. 1, 2 and 3, which show the protector in three different sections. It consists essentially of a series of lead plates, A, which are separated from one another by frames of blotting paper, B, dipped in paraffine so as to leave a small space between each succes-

sive plate. They are further maintained apart by narrow strips of paper, B. The whole is bolted together by end plates, D, and covered with a rubber sheet screwed down upon the top so as to enclose it completely.

By passing current through this arrangement the lead plates are slightly formed so as to develop a thin coating of per-oxide on one side of each plate and of sub-oxide on the other, constituting in fact a secondary cell. When this slight formation has been completed the sulphuric acid is removed and sulphate of zinc substituted to prevent any sulphating of the lead. With this solution the plates undergo no change, but the E. M. F. of the cells is raised to 2.5 volts.

The plates arranged in the manner shown and thoroughly inclosed are connected to the circuit in the manner illustrated in Fig. 4, which shows it applied to an electric railway system. It is evident that the positive terminal of the protector, L, is connected to the positive (+) side of the railway conductor system, and the negative (—) side of both the protector and the dynamo, M, are connected to earth. Thus with 200 plates in the protector, aggregating 500 volts, the same as that employed on the railway system, no current passes either into, or out of, the protector,

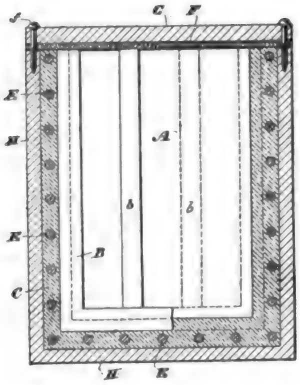


FIG. 3.—THE HOLCOMBE LIGHTNING POTECTOR.

as its potential is exactly counterbalanced by that of the line. But when the lightning discharge comes in over the line, instead of passing to earth through the dynamo having high self-induction, it passes directly through the protector, L, which, with the number of plates mentioned, has a resistance of less than one-fifth of an ohm and offers no self-induction whatever. This affords complete protection and saves the dynamo from injury.

On a system having a potential of only 220 volts only 88 plates would be necessary in the protector. These plates are about one foot square in area, and are composed of sheet lead as thin as it is possible to handle it, and for alternating currents Mr. Holcombe employs carbon plates instead of lead. The protector is evidently adapted for constant current circuits as well as for constant potential.

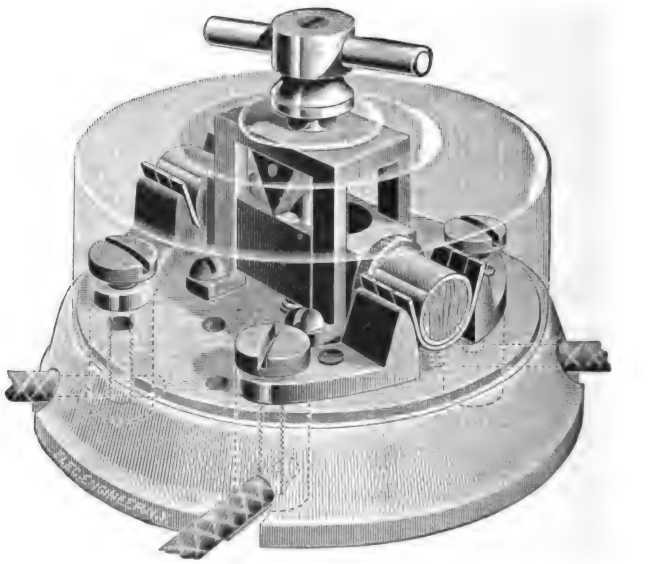
THE ROTATION OF THE PLANE OF POLARIZATION AS A MEASURE OF CURRENT.

IN 1851, Wiedemann discovered that if a tube containing bisulphide of carbon is surrounded with a wire carrying a current, the rotation of the plane of polarization is exactly proportional to the strength of the current. Starting from this point, M. d'Arsonval has devised a very simple arrangement for measuring currents and testing the accuracy of ammeters. In the apparatus recently shown to the Société de Physique, a coil of wire was wrapped round an ordinary saccharimeter tube containing pure water or bisulphide of carbon. The E. M. F. of a single Leclanché cell will cause a rotation of one degree. The apparatus can be made as sensitive as one pleases, since for a given current the sensibility depends simply upon the number of convolutions of the coil.

THE "NEW ENGLAND" SWITCH.

ONE of the most important details which go to ensure the success of an electric lighting plant are the switches for turning the lamps on or off. The requirements of a good switch are that it shall not only be able to carry the current safely without heating, but that it shall make and break quickly, so as to avoid sparking; and again that it shall be safe from grounds by being perfectly insulated.

These conditions have been well fulfilled in the "New England" switch recently brought out by the patentee, Mr. O. S. Platt, of Bridgeport, Conn., which is illustrated in the accompanying engraving. As will be seen, the



THE PLATT "NEW ENGLAND" SWITCH.

switch is operated by a handle to which a wedge-shaped piece is attached. By turning the handle the wedge is made alternately to press the brushes between the contact lugs, or to release them suddenly, by permitting a spring which has been compressed by the former operation to become free. The brushes are held firmly in place, not depending upon gravity or springs to hold them, but are firmly locked and can, as explained, only be liberated by turning the handle; when this is done the break is instantaneous, leaving no chance for the brushes to burn.

The brushes are perfectly insulated from every other part of the switch, being mounted at the ends of an insulating spindle which admits of the use of a metal handle not liable to become broken by abuse. The handle is held on to the spindle by means of one screw through the top, this one screw holding both the handle and cap in position.

The cap is of neat design, giving the switch an ornamental appearance, so that it is not necessary to put the switch in some inconvenient place for the sake of getting it out of sight. By removing the single screw the cap may be taken off at any time, even with the current on, with perfect safety.

Another very convenient feature of this switch is the manner of fastening the ends of the wires, which, as shown, are merely put straight into the slots in the porcelain base, and are held by one screw put down from the inside under the cap; the wire thus requires no bending or twisting, and hence also prevents the liability of a short circuit in connecting up.

THE BIDS FOR NEW YORK STREET LIGHTS.

Superintendent McCormack, of the Bureau of Lamps and Gas in the Department of Public Works, sent a report to Mayor Grant last week on his tabulation of the bids recently submitted by the various electric-light companies. He finds that the cost of lighting those parts of the city that are provided with electric-light lamps would, under the bids, be $77,678.65. The appropriation for that purpose amounts to but $71,507.29.

SOME DEFECTS IN PHYSICAL TERMINOLOGY.—II.

BY PROF. A. E. DOLBEAR.

Let it be admitted that a heated body sets up what we call undulations in the ether, that these waves have a wave length determined by the period of vibration of the atoms or molecules, and that the energy of the ether waves varies as the square of their amplitude, and let it be also admitted that there is not the slightest evidence that translational motion of a body of any size sets up waves in the ether, and it follows at once that what we call heat is the true vibration of the molecule and not its translational motion. That is to say, heat is the vibrational motion of atoms and molecules and its energy is proportional to the square of the amplidute of vibration.

If translational motion could impart to the ether any motion, of course a proportional part of energy would be observed by it, and the earth and other bodies moving in it would be slowing up. Now the velocity of the earth in its orbit is something like 17 miles a second, but the velocity of a molecule of hydrogen, the swiftest of molecules, at 0° C is but 1,843 metres, or only about $\frac{1}{16}$ that of the earth; so, if the earth movement sets up no waves, the free path of the gaseous molecule can much less. Again, the whole of spectroscopy teaches the same thing, namely, that the ether waves are set up by the internal vibrations of molecules and not by their external motions. As no other kind of motion is known that can produce similar effects, it would seem to follow that heat will be correctly defined when the character of the motions are specified.

When motion of one kind is transformed into another kind, the character of the energy is transformed also, and what a given amount of energy will do depends altogether upon its form, not upon its quantity; that is to say, vibratory energy has possibilities that do not belong to rotary or rectilinear. The vibratory motion of the piston of a steam engine must be transformed into rotary in order to advance the train, and if we named the vibratory motion of the piston x to distinguish it from other kinds, it would tend to nothing but confusion to speak of the rectilinear motion of the train as x motion, simply because it was the result of x motion; yet this is precisely what we do when heat is treated either as a translational motion, or as an undulatory motion in ether. There is the assumption that heat exists in three forms: I. The true vibration of the molecule; II., the translational free path motion, and III., the ether undulation when as both the translational motion and the ether waves are the *results* of the vibration of the molecule, the one by impact, the other by absorption; the one a transformation of vibrating into rectilinear free path motions, the other both a transformer and a transformation. To call each of these by the same name is to confound entirely different phenomena—an effect with a cause.

In every case where there is a so-called transformation of energy, what really happens is, a transformation of motion, hence if the various forms of motion have specific names the inconsistances will all disappear.

Third. It is but a short time ago that we were taught that there were three kinds of radiations from heated molecules—heat, light and actinic rays; but photography and the bolometer have rendered that statement quite untenable, for it has been discovered that what ether waves will do depends upon what they fall upon. One body will have its temperature raised, and we say it is heated; another body has its molecular structure broken up, and we say it has been chemically acted upon; and still another has a sensation incited, and we say it is the effect of light. Now that light is known to be a purely physiological phenomenon, and that there is no such thing apart from eyes; and even with the probability that what goes on in the eye itself is of the nature of photographic action, the general explanation of all the phenomena has been changed, but the terminology remains to mislead even those who are more or less familiar with the facts, as when one speaks of "the velocity of light," of the existence of "dark and light heat rays," and of the "temperature of space." If light be a physiological phenomenon, it cannot at the same time be an undulation in the ether; neither can dark and light be applied to the same phenomenon, nor can empty space have a temperature, as temperature is a condition of the molecules of matter. The term, radiant energy, has sometimes been used as a substitute for radiations, and in Daniell's "Physics" the whole range of undulatory motions in the ether is treated under the general head of Ether Waves. This is better than the other, yet between these two there is this discrepancy, that motions of any sort cannot properly be called energy, for, as said before, energy is a product and motion is but one of the factors.

Fourth. In the subject of electricity the lack of definitions in the terminology has led to a great deal of confused thought, but our actual knowledge of the character of electricity is much greater than many suppose it to be. Maxwell and others have asserted that whatever it may be it is not energy, while others, as represented by Preece in his late presidential address, assert that it is energy. Curiously enough Maxwell declares that it cannot be energy because electric energy is a *product* of electricity, E, into a current, C.

Edlund and some others have thought electricity to be identical with the ether, while still others have imagined it to be a fluid, or two fluids, or some kind of matter with the fundamental property of matter, namely, *mass*, left out. It is not very difficult now to see how such varied conceptions arose. An electrified body affects the space about it, or as we now say, it produces an electric field which is known to be a stress in the ether, and that implies a strain in the electrified body. It is also known that such stress is propagated in the ether with the common speed of ether waves, namely, 186,300 miles per second. The speed of this movement has been measured by so many and in so many ways that there is no doubt about it, and since the experiments of Hertz there is no room for doubt as to the existence of the ether.

What we now know is that states of stress in the ether are propagated at a definite rate in it, which rate depends not upon the source of the movement but upon the property of the ether to transmit movement; so, whether heat movements or electrical movements are antecedent makes no difference. We find no difference in perceiving the relation between the vibratory molecular motions and the resulting waves in the ether, but here is a precisely analogous case of electrified molecules and the ether propagating a motion, which implies, if anything, that molecular motion is the source of the ether displacements. One person will give chief attention to what is going on in the electrified matter, and another person to what is going on in the ether, and they come to different conclusions as to the nature of electricity, while a third person who notes their discrepant notions concludes that no one knows anything about it. What we call electricity originates in matter, and there is no evidence whatever that it ever originates apart from it. As Rowland has somewhere said: "It begins in matter and ends in matter." The conditions for its origination are differing and interfering molecular motions, whether in a thermopile, a galvanic battery or a dynamo; the conditions for its transference are a continuous material conductor, for it cannot traverse a vacuum. The effect upon the ether we call an inductive effect; and just as in heat phenomena we have a transference and a transformation, so is there also in electrical, both a transference and a transformation. In heat phenomena, where matter is placed in the *thermal field* so that the ether undulations fall upon it, the matter is heated. Likewise, when matter is placed in an electric field the matter is electrified. The cases are exactly analogous, and one is therefore justified in making the terminology appropriate to the phenomena; and whenever there has been a transformation in the motion, another name ought to be adopted and

not let the old one do double duty. If molecular motions of any kind be called electricity, then it is not proper to call any effects in the ether by that name. If the effects we study in the ether be called electricity, then do we need a name for what takes place in matter, for one is the effect of the other.

If one adopts the doctrine of the conservation of energy, and also that the matter of the earth is practically a constant quantity, it will lead him to conclude that all the varieties of energy are due to the various forms of motion that matter may have. If, also, one perceives that motion of any kind, at any place, implies antecedent motion, he will not feel the necessity for looking for hyperphysical explanations for any physical phenomena. For instance, when one sees the light and feels the heat from an electric arc lamp, knowing the nature of both the light and heat as being but particular forms of motion—one in matter, the other in the ether—he could logically look for nothing but some kind of motion that had been transformed to produce such effects. It is entirely immaterial what the character of the motions may be that produce electrical effects—that may remain to be determined by experiment—just as in the case of heat after the work of Sir Humphrey Davy and Count Rumford, it was then settled what the *nature* of heat was, namely, a molecular motion of some sort and not an entity. It is only within a few years that the character of the motion has been determined. In like manner we may say that we know what the *nature* of electricity is—that it is also molecular motion of some sort to be experimentally determined.

There are numerous reasons for thinking it to be a rotation as distinguished from a vibration. One of the chief of these comes from a study of electro-magnetic effects in the ether. It is generally agreed that this magnetic effect in the ether is of the nature of a whirl, or rotation, and in numerous treatises these whirls are pictured, but I do not remember to have noted that anyone has pointed out that a whirl in the ether implies a rotation of a molecule, for a similar reason that an undulation in the ether implies a vibration of the molecule. To me this appears to be necessary, but whether the motion be that or some more complex kind does not so much matter—it will be discovered in time.

Fifth. There is one more important matter I want to allude to and that is the expression first used by Maxwell, namely, "Light as an electro-magnetic phenomenon." Waiving for the time the criticism that light, being a physiological phenomenon, is therefore entirely inappropriate here, there still remains this fact that the ether waves from heated bodies move in straight lines, and unless deflected by the reflections and refractions of matter, will continue indefinitely on in the same straight line, making the *field of a heated body* as extensive as the universe; while the field of an electrified body depends upon the proximity of masses of matter, and practically is always limited in extent, and the observed lines are always curved. So if the two kinds of waves were really parts of the same movement, what is called a ray of light would seldom or never be found to move in a straight line for any considerable distance. If, on the other hand, the wave that originates in a vibration continues in a straight line only so long as it moves in homogeneous ether, and has its place of vibration changed by passing through a space of ether that has been electrically warped, as we experimentally discover to be the case, it would seem to follow that the two kinds of motion in the ether are fundamentally unlike. Either can exist without the other, and therefore they ought not to be called by the same name.

I have arranged the various elements concerned in physical phenomena into a table that presents at a glance the various motions involved in mechanical and molecular phenomena.

Elements of physical phenomena.
- Substance.
  - Ether—Simple. (Homogeneous).
  - Matter. (Heterogeneous.) Elements and their compounds.
- Motion. Rectilinear, Vibratory, Rotary and their compounds.
  - *In matter* called $Mv =$ momentum, $\frac{Mv}{2} \times v =$ energy.
    - *Mechanical*, if visible.
    - *Atomic* or *molecular*, if invisible.
      - External. Translation or free path.
      - Internal. Vibratory—Heat. Rotary?
  - *In ether.*
    - Rotary.......magnetism.
    - Undulatory.....ordinary light.
    - Spiral.......polarized light.
    - Vortical......matter?

THE PASSIVE STATE OF IRON AND STEEL.

In a paper on this subject recently read before the Royal Society, Mr. Thomas Andrews gives the results of his latest investigations in this direction. The results afford an indication that magnetization of comparatively low intensity, acting during considerable periods of time, exerts only a limited modifying influence on the passivity of iron or steel in the cold, though the influence is discernible when employing a delicate galvanometer. Magnetization, with the nitric acid at a higher temperature, produces a quicker effect. In a recent research by the author, on "Electro-Chemical Effects on Magnetizing Iron," it was noticed that local currents were set up between the polar terminals and central portions of steel magnets exposed as electrodes; and this class of local action, together with the slight alteration of the physical structure of the magnet bars consequent on their magnetization, may possibly be involved in producing the effects due to magnetism on passive steel or iron in concentrated nitric acid.

AN IMPROVED CONNECTION FOR CARBON BATTERY PLATES.

A USEFUL little improvement in the way of connecting the carbon plates of batteries has been devised by Mr. Dopping-Hepenstal, R. E. A small hole is drilled through the carbon plate about ¼in. from the upper edge. A piece of platinum wire, 24 or 22 S. W. G., is next snipped off obliquely, so as to form a chamfered end, and the last quarter of an inch or so of the piece is bent back upon itself, and pinched tight. The piece is then passed through the hole in the carbon plate, and pressed in hand tight, until arrested by the swell of the loop. A length of two to three inches will usually be found convenient. The plate may be partially or totally submerged in the exciting fluid. It does not matter whether the actual junction between carbon and platinum is above the level of the exciting liquid in the cell or below it, the platinum being, for all practical purposes, incorrodible. Thus a Leclanché cell can be sealed up, the carbon plate being entirely within the cell, and connected to the outside by a single platinum wire passing through the seal.

COMPLETION OF THE BERMUDA-HALIFAX CABLE.

Bermuda congratulated New York last week on the completion of the cable connection between that place and America. The mayors of St. George and Hamilton, Bermuda, sent a cable message to Mayor Grant. The mayor of Hamilton says that he hopes that connection with the Great America will cement the good feeling, increase commercial interests and prove in every way beneficial.

THE BREWER AND SMITH ELECTRIC VISUAL POLICE SIGNAL SYSTEM.

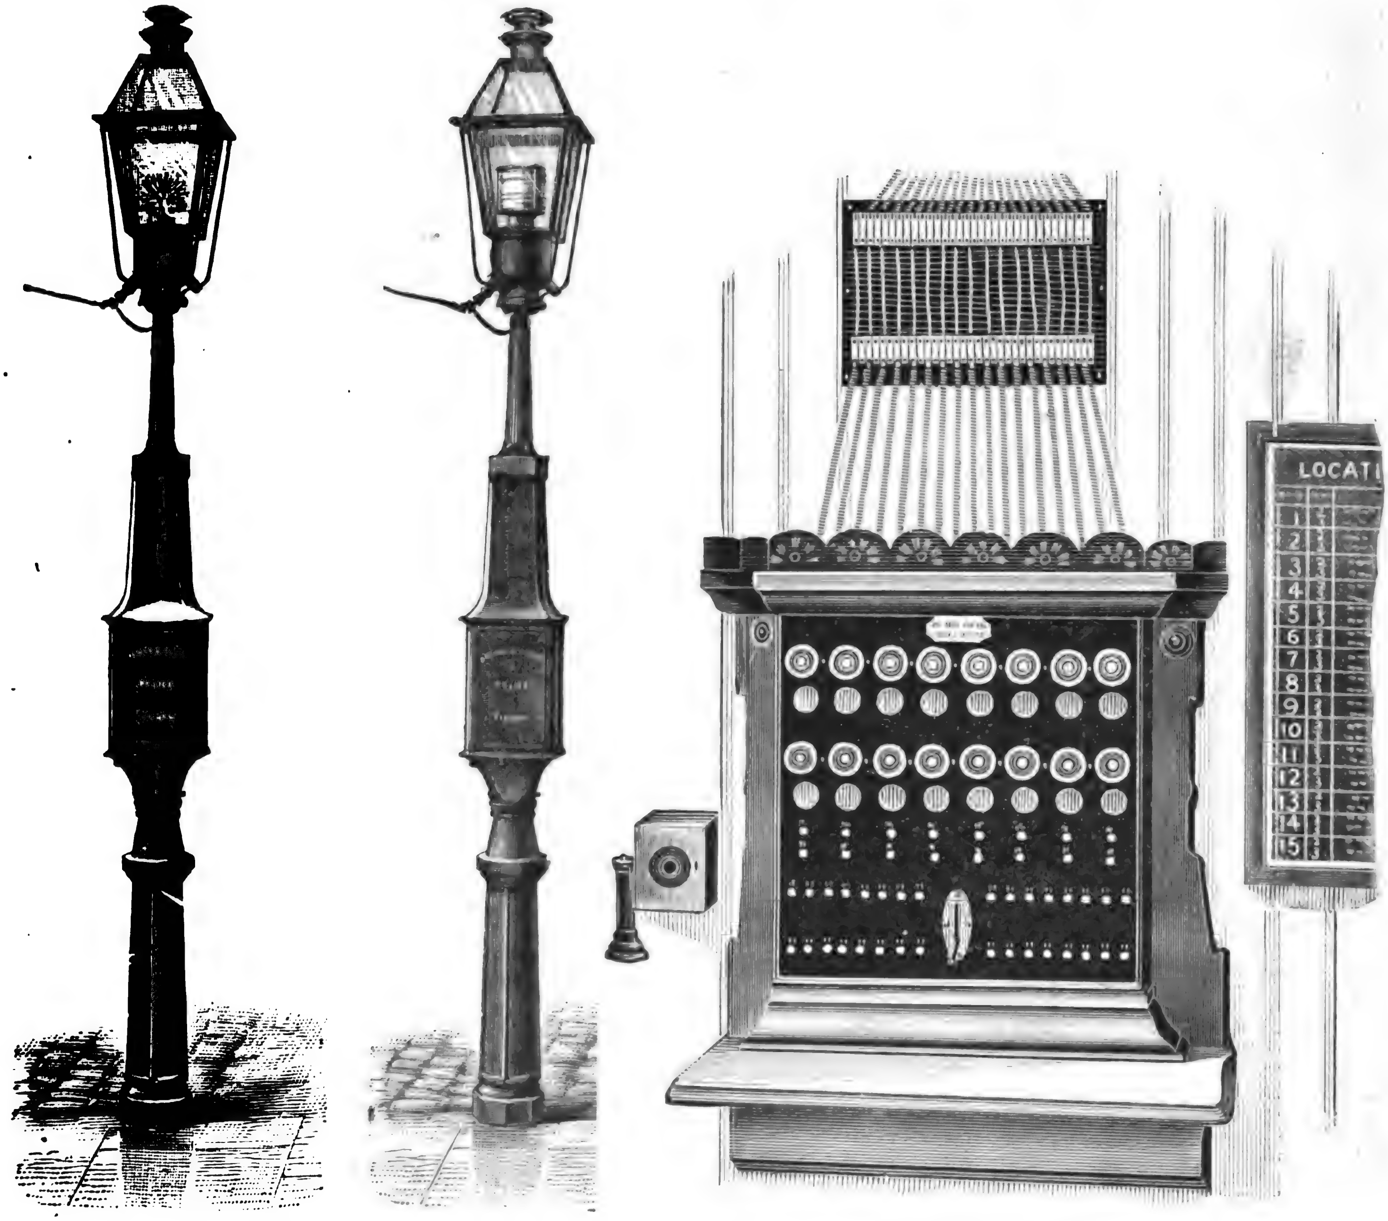
It has long been recognized that in large cities where policemen are frequently stationed at a distance from headquarters, some means of communication between them is necessary for a thorough protection of the city. A variety of systems designed for this purpose have been put into use in various cities, but almost invariably they have been of such a nature that while the officer on patrol could attract the attention of headquarters, the latter was unable to draw the attention of the officer on patrol, when at any distance from the signal box, especially at night.

To obviate this difficulty, therefore, Mr. James P. Brewer, of the New Haven, Conn., police force, and Mr. W. C. Smith, superintendent of the police and fire alarm telegraphs of that city, have designed what is known as the electric visual police signal system. It consists essentially of a visual signal united with the telegraph and telephone, which gives the officer at the desk the power to attract the attention of, and communicate with, any policeman, in any part of the city, no matter at what distance he may be.

The accompanying engraving, Fig. 1, represents one of the street stations, on the summit of which is an ordinary gas lantern or electric light, which, just the same as any gas lamp with its supporting post or electric lamp, furnishes light for the city streets. The engraving represents the visual signal as down or out of view, it being dropped below the light of the street station.

By the touch of an electric button at headquarters, an armature is released, and a red globe at once rises from inside the alarm box which encircles the gas or electric light as shown in Fig. 2. The change of color is seen by night on a street for a long distance, and in the daylight the colored signal can be seen for some blocks. The patrolman on his beat is thus notified that communication with headquarters is desired, and promptly responds through the telephone from the signal station to which the signal alarm has called him. After communicating, the colored glass globe is allowed to drop to its place of concealment. In the same manner as the central office can communicate with any patrolman on his beat, he can summon assistance from any adjoining beat, by opening the iron box, and, by a touch, releasing the armature which controls the ascent of the colored glass.

The box contains a complete set of signal, call, and telephone apparatus placed in a cast iron structure, simple and unique in design, forming no more of a street obstruction than the ordinary lamp post, and can be attached to any of the ordinary lamp posts in use in different cities. This



Figs. 2 and 4.—Brewer and Smith Electric Visual Police Signal System.

signal station is about eight feet in height, octagonal in shape, and of hollow construction ; midway it enlarges into a cast iron box sufficient in size to contain a telephone, transmitter, transmitter battery, calling and visual signaling apparatus, and the necessary lightning arresters and switches, all the apparatus being protected from damage by rain or snow. Inside and above the call box is an apparatus, with counter-balance weights, which holds in position the concealed red glass globe.

The engraving, Fig. 3, gives an interior view of the street signal station, the door being open. *a* shows a handle at one side of the interior of the street signal box. It is attached to a magnet which is used by policemen to signal to the central police office, making known there that the policeman wishes to communicate by telephone, or that he wants a patrol wagon or ambulance. By means of the button *b* the policeman can operate the visual signal mechanically, and when so used it will call help from neighboring beats and with perfect silence. *c* is a hook by which the policeman pulls down and retires the colored visual signal. There is a telephone inside of each street station, and a transmitter by which oral communication is effected.

FIG. 3.—THE BREWER AND SMITH POLICE SIGNAL.

The entire apparatus required at the central office is shown in the engraving, Fig. 4. It consists of annunciator drops, bells and push buttons, together with a telephone set. If a policeman on one of the lines or circuits makes a call, the annunciator drops and a bell rings. The number of rings shows by the code what is wanted. At the central office two lines can be connected, so that a policeman in one part of the city can send word to a policeman in another part, but as it passes through the central office it can be heard there by the officer in charge. The lower set of buttons seen in the cut, when pressed, raise the visual signal at any desired point in the city, and call the policeman desired.

It is evident that with a system of this kind the police force is raised to the highest standard of efficiency. Its operation in New Haven has been attended with the most satisfactory results, and we are informed that an installation of a dozen signal boxes is being set up in London by the police authorities there.

INFLUENCE OF MAGNETISM ON FLUORESCENCE.

BY PROF. A. E. DOLBEAR.

In the issue of THE ELECTRICAL ENGINEER for June 25, "J. J. J." asks for a publication of any experiments bearing upon the effects of strong magnets upon the phenomena of fluorescence or phosphoresence. The following experiment by myself may have some interest for him and perhaps for others.

I studied the effects of a strong magnetic field upon the phosphorescence phenomena in Crookes' tubes, of which I used several different kinds. The tube was charged by permitting sparks from a Holtz machine to fall upon one terminal. It was thus made to assume a sensitive state and could be removed several feet from the Holtz machine and the glow kept up while the machine was being turned. Under these conditions the tube was placed in a magnetic field produced by a strong electro-magnet, operated by a Morse key, and I found that the magnetic field could entirely control the luminous effects in the tube, being stopped entirely by the field of the magnet, and instantly restored by the electric field when the magnetic field was destroyed. So that the Crookes' tubes gave Morse signals where thus controlled.

Theoretical considerations led me to doubt the statement that the aurora borealis was due to electrical *currents* in the rare atmosphere in high latitudes, which has generally been the explanation given of the phenomenon ; and to test the effect of a magnetic field upon electrofied molecules the above experiments were tried. As the result of these experiments, I sent a paper to *Science*, which was published May 3, 1889. The experiments were not alluded to in that paper, because I considered there was nothing in them except what was easily deducible from what was already known.

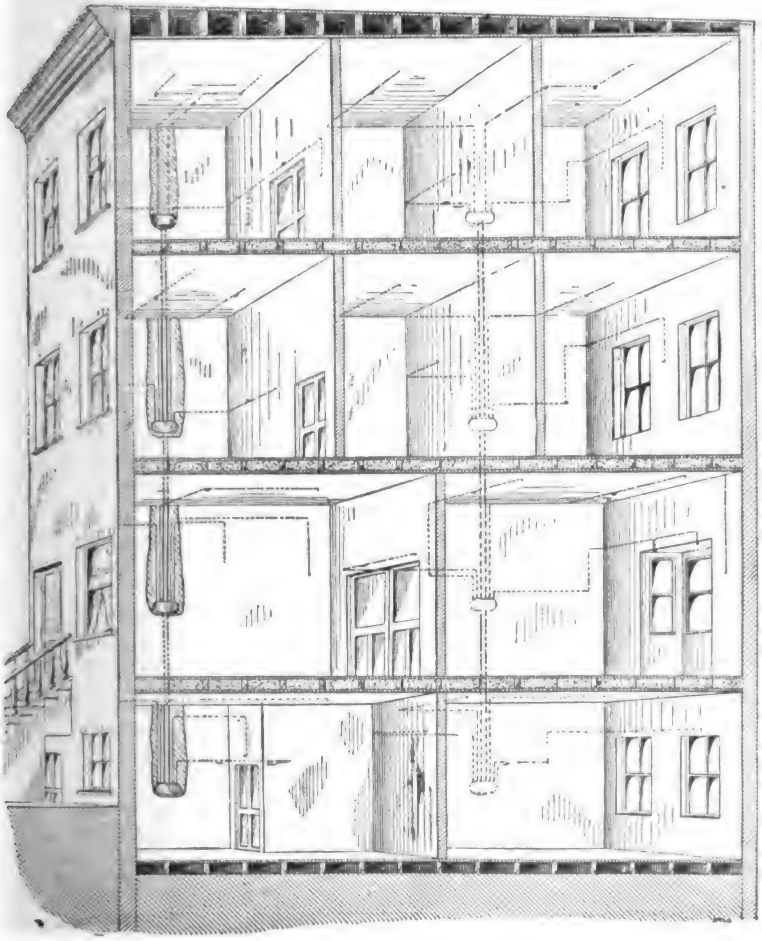
ACCUMULATORS AT THE BERLIN TELEGRAPH OFFICE.

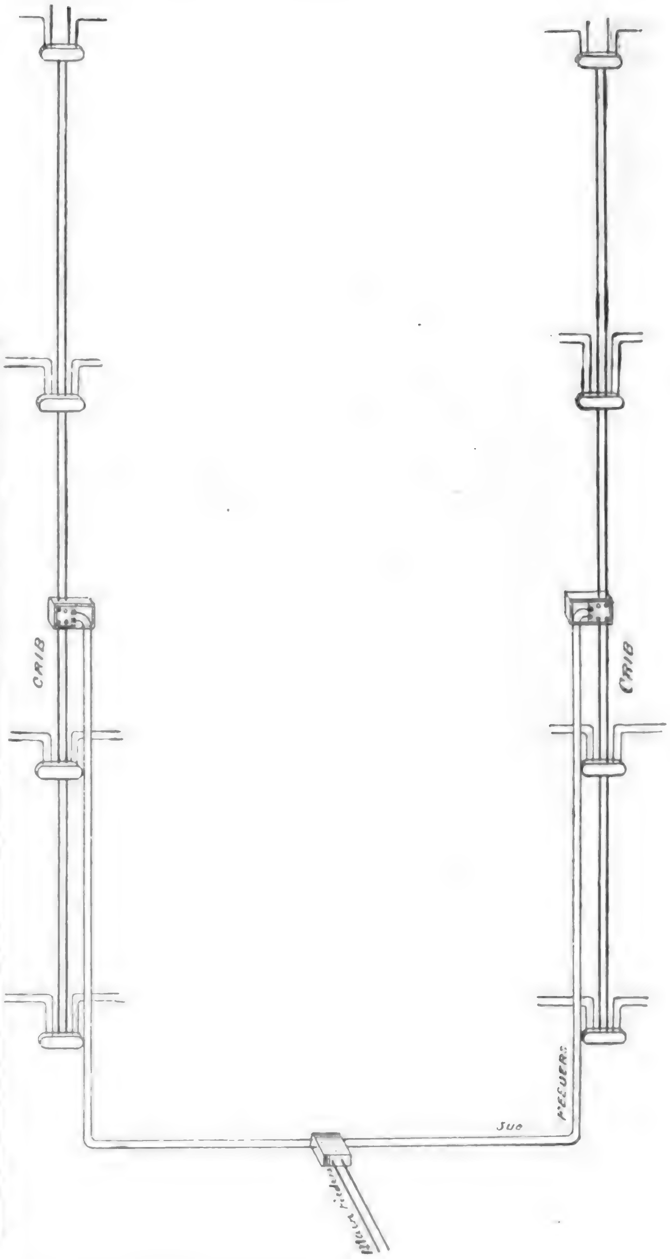
In a paper recently read before the Elektrotechnischer Verein, Herr Strecker, chief engineer to the German Imperial Telegraph Department, gave a brief account of the accumulators, which had been installed in Berlin in connection with the telegraph service. In October last a battery of 25 Tudor accumulators, having a capacity of 25 ampere hours, was installed at the Berlin telegraph offices. The cells are charged with a current of 7 amperes by a shunt-wound Siemens machine, driven by a 5 horse-power Otto engine. The current is conveyed to the central office, distant 1.7 kilometre, by means of a seven-wire cable, each wire having 5 ohms resistance. Only three wires are at present used, and they convey the current in the following manner : The first, starting from the eighteenth cell of the battery, supplies 36 circuits at 34 volts ; the second, starting from the twentieth cell, supplies 12 circuits at 40 volts ; the third starts from the last cell of the battery, and supplies 13 circuits at 50 volts, six circuits at 60 volts, and one circuit at 80 volts. In the two last circuits 10 and 30 primary cells respectively are added to the secondary cells. These 68 lines comprise 41 Morse and 27 Hughes circuits. The negative pole of the battery is connected to earth. The average discharge is at the rate of 60 milliamperes, so that the accumulators can supply this from 30 to 40 days, although, as a matter of fact, they are charged every ten days. The charging is effected in the following manner: The dynamo is switched on to the accumulators through a very high resistance, so that the charging current is at first very small indeed. A wire is taken from the centre of the battery to earth through a voltmeter, and when the E. M. F. rises by about 2 volts, the engineer in charge, by means of a switch, switches out a cell from the telegraph circuits, still leaving it in the charging circuits. The charging current is then increased, and as the E. M. F. rises still further more cells are switched out. The reverse process is gone through on stopping. The difference of potential on the telegraphic circuit during the charging operations is kept so uniform that no complaints have ever been received from the central office. Since the cells were first employed in the beginning of October, 1889, they have worked in an irreproachable manner, and the authorities are so satisfied with them that they now propose to adopt them on a far larger scale.

THE THOMSON-HOUSTON ELECTRIC CO. has organized a department for testing raw materials at the Lynn factories. It will be located in the basement of the new office building on Centre street. Felix Cleeverg, of the Sheffield Scientific School of Yale College, will perform chemical work in this department.

WIRING METHODS OF THE INTERIOR CONDUIT AND INSULATION CO.

One of the main features of the wiring system of the Interior Conduit and Insulation Co. is its employment of an insulating tube through which the conductors are carried, so that all the wiring of a house or public building lies in familiar, well-defined channels, and is at any moment accessible for inspection, extension or repair. Hitherto, wiring has been but too often a haphazard kind of work, so that its exact location was determined chiefly by the traces of its imperfection; and the effort of making changes and ameliorations has resulted in dismal disfigurement of walls and ceilings. The company have recently been preparing a catalogue and price-list for publication, and one of the illustrations shows the manner in which a house is wired up. We have reproduced this interesting cut in Fig. 1. In connection with this, another view, that in Fig. 2, is also important, bringing out as it does the "crib" system employed by the company. It has demonstrated by experience that electric light wiring can be done most economically and effectively by the establishment of centres of distribution wherefrom to radiate all minor branch circuits; and the system has been modeled in its entirety





Figs. 1 and 2.—Wiring Methods Employed with the "Interior Conduit" System.

upon this plan, by means of which really good work can be had. For mains and feeders the company advise a separate tube for each conductor, in which a rigid wire with either underwriters' or weather proof insulation may be employed, but for branches the special flexible twin conductor, with both conductors in one tube is resorted to. It is easily seen from the cut of the house that by employing as many "risers" as possible, long lateral runs, which are objectionable, are thereby avoided.

This system also has led to the invention of many new and useful appliances which greatly facilitate and reduce the expense of the installation of this admirable method of electric wiring, one for which none but words of praise and hearty recommendation are due.

The success met with by the Interior Conduit & Insulation Co's. system has borne out the estimate made of its utility. Not only are all the new buildings in the East, in course of construction, equipped with it, but it has also been specified by architects in other new buildings throughout the country, among which are the Board of Trade Building, Toronto; the Boston Building, Denver, Col.; the Bell Telephone Building, Boston, Mass.; New Jersey Central Depot, Seventh Ave. Music Hall, German Club, etc.

The fire last week in the Western Union building, could not, we believe, have occurred had the wires from the battery room to the switchboard been carried, individually, in the small tubes of the "interior conduit" system. It would have been practically impossible to start the fire by a short circuit or cross; and even had it started it could not have maintained itself. It is to be hoped that when the new switchboard is built, the wires from the battery room, instead of being massed together, as they were, in one big tangle, will ramify in a scientific manner through a system of tubes. The reform will be one of the best that the disaster presents an opportunity for.

CORRESPONDENCE.

PITTSBURGH.

Electric Railway Work—Tesla Motors—An Electric Cab Co.—The Allegheny City Plant.

The Duquesne Traction Company has just broken ground for the foundation of its new car stable, which is to cost $70,000. The structure will be two stories high with dimensions 165 by 400 feet. The excavations for the power house of the Birmingham Traction Company have been started at Carson and South Thirtieth Streets. This building will be erected at a cost of $15,000. Both of these roads are about to adopt electricity as the motive power on their lines.

The small motor of the Westinghouse Electric and Manufacturing Company is now being used on the vestibule trains of the Pennsylvania lines. The library car of the Chicago limited has been furnished with several of the motors attached to fans.

The Citizens' Traction Company held a few days ago a meeting and unanimously agreed upon an increase of the capital stock of the concern from two and a half to three million dollars. This increase is to be used for the purpose of extending the road from its present terminus to Sharpsburg, a distance of one mile. The financial statement submitted by the company for the first six months of the year shows their receipts to have been $288,061.92 and their expenses $199,617.57, making a net profit of $88,444.35.

It must not be forgotten that this road is a cable line and as the company is even at its present enormous expenditure earning an eight per cent. dividend, there is no telling the profits they would make should they adopt an electric motor system.

Pittsburgh is evidently determined that nobody shall outdo her in the development of rapid transit. The latest project about to be launched here now is the organization of an electric cab company. All preliminary arrangements for this plan seem to have been already concluded and the cabs are to be running as soon as possible. The cause for the introduction of this novelty however has been this: Ever since the Pleasant Valley electric line and the Second Avenue electric railway have been in operation and have demonstrated the great success of electric roads, the rush to obtain rapid transit franchises has been extraordinary. The result has been that there is scarcely a street in Pittsburgh and Allegheny to-day where it is not proposed to lay tracks and run electric cars. Of course in the race for obtaining council's permission, the favored parties and those with the best political influence got the best of their competitors who were less fortunate. It is in order to get even with the political favoritism that this cab company has been organized, because to run a cab along a street no special right of way is required. The cabs are to be modelled after the system which has been operated for some time in London and other European cities, the vehicles to be propelled by the storage battery method. The company intends to place 40 cabs on the streets to start with and increase this number as travel demands.

The new electric light plant of Allegheny City commenced operations last night for the first time and everything was pronounced a great success. The plant consists of 3,000 alternate current incandescent lamps and 500 arc lamps of the Westinghouse alternate current system.

PITTSBURGH, July 18, 1890.

BOSTON.

Annual Meeting of the Massachusetts Electric Lighting Association—Hospitality of the Officers of the S.S. "Minia"—Construction on the West End Street Railway—A Hint for a Safety Device in Open Cars.

THE first annual meeting of the Massachusetts Electric Lighting Association was held yesterday afternoon at Hotel Pines, Point of Pines. This association includes 30 of the leading local electric lighting companies in the state, representing a capital of $5,000,000, and 50 representatives of these various companies were present. The treasurer's and attorneys' reports were read, and the following officers elected for the ensuing year: President, Frederick A. Gilbert, of the Boston Electric Light Company: first vice-president, Hon. Theodore C. Bates, of the Worcester Electric Light Company; second vice-president, George W. Fifield, of the Lowell Electric Light Corporation; Executive Committee, Frederick A. Gilbert, Hon. Theodore C. Bates, George W. Fifield, C. L. Edgar of the Edison Illuminating Company of Boston, and C. A. Nichols of the United Electric Light Company, Springfield.

After passing a vote of thanks to President F. A. Gilbert for his able and efficient administration of the affairs of the association, the meeting adjourned to the dining hall, where a substantial repast was enjoyed.

The steamship "Minia" is attracting numbers of electrical men as it lies in Boston Harbor at present, and all are warm in their praises of the kindness of Captain Trott and his officers, who vie with each other in tendering true English hospitality to the visitor. The captain's "gig" leaves the wharf at the foot of State street every day at 1 o'clock, and daily there are small parties made up to go aboard and inspect the mysteries of the cable ship, and enjoy the pleasure of luncheon served up in true nautical fashion. There is an abundant supply of genuine English soda water on board, which, when mixed up under the eye of the genial captain, who generally manages to drop a cinder in it, composed of the "rale Glenlivet," has a most composing effect on the fagged brains of the weary shore-worker. Cool breezes and sparkling conversation on the deck "far from the madding crowd" tend to make a visit to the "Minia" extremely pleasant and not easily forgotten. Captain Trott's experience as a cable layer and cable repairer is unequaled, and now and then he can be induced to say something about it.

The West End Street Railway Company are taking every advantage of the fine weather to increase their tracks and overhead construction everywhere in and around Boston, and are now handling the immense crowds which visit Franklin Park nightly, with the utmost despatch. The tracks on Columbus avenue will be relaid this year, and work is now being carried on on Federal street, which involves the moving of the tracks of the Union Freight railway to the side of the street. Washington street is also receiving attention, and this line will soon be completed. Brighton, Everett, Cambridge and Somerville are also being thoroughly equipped, and heavy ⊥ rails being substituted for the light ones used by the horse cars. Electric railways are certainly a great attraction for the multitude, especially in the hot summer weather when open cars are in use, so that one can enjoy a long ride through the suburbs without witnessing the struggles of poor hard-worked, panting and overheated horses. Last week saw a fatal accident to a man who carelessly stepped off a car *on the wrong side* in front of an approaching electric car, and was instantly killed. During the past winter gates were put on all the closed cars on the side next the other track, just to prevent such accidents, as it is an easily observed fact that about 90 per cent. of people getting off cars will insist upon stepping off from the wrong side. Some arrangement for the open cars, apparently, could easily be made, and a wooden bar running the entire length of the car, it seems to me, would effectually prevent people, especially ladies, from stepping off in front of an approaching car. The writer well remembers seeing open cars used in Belgium with such a device, though there was a passage through the centre of the car, and with a car provided in this way it would be difficult for such an accident to recur. The bar could easily be changed from the one side of the car to the other at the end of the route, and its use would at least inspire the public with confidence in the company, and in the belief that all was being done that is possible to prevent accidents. A few would undoubtedly kick at first at the extra five seconds required in getting off and on, but they would soon get used to it, and sooner or later appreciate it, especially if they would only watch a few times as a car goes rushing past at about fifteen miles an hour and think how much chance they would have of escaping if they had stepped off unwittingly at that time.

BOSTON, July 19, 1890.

CHICAGO.

Objecting to a New Station—Examining Steam Engineers—The Smoke Nuisance—Prof. Gray for World's Fair Electrician.

A STRONG protest in the shape of an injunction bill has been filed in the Superior Court against the erection of the proposed new electric light plant of the Chicago Edison Company, at Nos. 2,638, 2,640 and 2,642 Wabash avenue. The plaintiffs are residents in the near vicinity of the proposed station. The dwellings of the plaintiffs, it is alleged, were erected with the idea that Wabash avenue was, and would remain, a quiet residence street away from noise and smoke of all kinds. It is charged that the Edison Company has excavated for foundations and is proceeding to build a large electric plant, whose furnaces will produce volumes of smoke, while the noise of the engines and dynamos will unfit the neighborhood for residence purposes.

The board of examining engineers, which is to examine and give certificates to all engineers before they can take charge of an engine, in pursuance of an ordinance passed by the Council last April, met at the office of the commissioner of public works this week and organized. S. F. Kerns was made president and E. C. Dicey, secretary. The other member of the committee is J. J. Keely. Mr. Dicey's salary is $1,500, and that of the other members $500 a year each—all to be paid out of the receipts from certificates, which will cost $2 each and be good for one year, when they can be renewed upon application and the payment of $2. The regular examining day will be Monday of each week. The board prepared a notice to be inserted in the newspapers announcing the provisions of the ordinance and fixing the first examination day for Monday, July 21. The board will meet twice each week, and the secretary will have a permanent office with the commissioner of public works.

The health department is stirring up the smoke nuisance offenders again and intends to begin a number of prosecutions. The department is investigating a number of new smoke consumers,

One of the most important questions now agitating Chicago is the smoke nuisance. The following described devices are some which are claimed to be highly effective: There are three devices used in this city which are quite effective smoke-consumers, or rather smoke-preventors. One of these is the Olson device, used in *The Tribune* building, by which steam sprays from coils of pipe on either side of the grate-bars are sent over the fire-bed at a suitable height. These sprays help to intensify the flame and prevent the generation of smoke. The device is simple and durable and its application is easy. Another device is the brick arch at the rear of the grate-bars and under the boiler. This is the device used so successfully by Gregsten, Field, and others in their furnaces. It causes a down draft, forcing the gases arising from the coal on the grate-bars to whirl down under the arch when the flame is strong and hot and thereby smoke is prevented from forming. This down draft principle is really the best that is easily available for coal smoke combustion. Another good device, and on the same principle, is the Ritter furnace, in which the arch is outside of the boiler. It is on this principle that the Boston complete combustion furnace is constructed, and it is an effective smoke preventive. So is the Murphy self-feeding furnace, but it is costly.

The name of Professor Elisha Gray has been mentioned for the office of electrical director of the World's Fair. Prof. Gray is a scientist in the highest sense of the word, and his name is known from one end of the country to the other, and scarcely less familiarly on the other side of the Atlantic. He is not merely a practical man, but something more—"a savant."

CHICAGO, July 18, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

THE NEW UNIT "HENRY."

[130.]—I was very much interested to see that Mr. Chas. Steinmetz in his paper on the rectifying of alternating currents, contained in your issue of July 16th, made use of the name "henry" for the unit of self-induction. Although it is only a few weeks since I proposed this name, I believe it will not be very long before the term "henry" is in general use.

I can remember distinctly that it was hardly more than a year from the time the scientific journals began to use the terms "volt," "ohm" and "ampere," until these words were in everyday use among the common workmen in electrical factories and stations.

FRANCIS B. CROCKER.

AN ELECTRIC LAWN PARTY AND ELECTRIC FIREWORKS.

Mr. Edw. H. Johnson, the president of the Interior Conduit and Insulation Co., has a fine country residence, "Alta Crest," at Greenwich, Conn. His house is situated about four miles from the Sound, in the centre of a plot of ground of 33 acres, which, according to the United States geographical survey, occupies the highest point of land between Maine and Florida, a like distance from the coast. On account of the electric light and the electrical proclivities of its owner, the place has been very appropriately named "Electric Hill." The house itself is of the colonial style and from its spacious porticos a magnificent view on all sides is spread before the observer. The lighthouse off Bridgeport shoals is plainly visible 33 miles distant—such is the vista. The house stands on the apex of the hill and the broad-winding driveway which leads up to it by a circuitous route is lighted by numerous incandescent lamps on ornamental poles. An Edison plant supplies the light and power for the house as well as for the spacious stables and lawns.

Within the house itself Mr. Johnson has carried out many novel ideas in regard to lighting as applied to decorative effects as well as in regard to the useful application of electric power for household work.

In the groined, oaken hall, a large handsomely finished organ pours forth melodious music by the hour, by the simple manipulation of an ordinary electric switch. An apartment over the porte cochere, known as Mr. Johnson's "Den," contains trophies from all parts of the civilized and uncivilized world. An electric cigar lighter lies handy to an open box of cigars on a table. Two electric cooking stoves keep the late supper warm, while an electric teapot simmers on the sideboard and has been found convenient in supplying other warm decoctions besides the five o'clock cup. A huge horned owl blinks electrically, with large yellow eyes, from his perch in one corner across the room at a hideous bearded Chinese mask, which emits the red fire of passion from its open eyes, mouth and nostrils. Between the two is suspended in mid-air, a large specimen of porcupine fish, within whose transparent and bristling skin is concealed an incandescent lamp sufficient by itself to light the room. Electric fan motors cool the air when necessary. On one side of the room stands what may now be termed a relic—one of the first phonographs ever made, a monument to tin foil, lung power and muscle; while on the other stands the very last instrument, especially constructed for Mr. Johnson, at the phonograph works. The drawers of the cabinet contain a choice selection of musical cylinders which prove an endless source of entertainment to everyone.

On Saturday, the 12th inst., Mr. and Mrs. Johnson received some 300 guests at their annual lawn party, given in honor of the birthday of their daughter, Miss Edna Earle Johnson. For this occasion a large dancing platform 40 x 25 feet was erected on the lawn in front of the house, covered with crash and illuminated by strings of Chinese lanterns, each with an incandescent lamp within, suspended in festoons from decorated poles at the corners. Outside the house, the decorations consisted principally of artistic effects produced by an elaborate arrangement of incandescent lamps of all colors. Between each post of both the upper and lower porticos encircling three sides of the house were suspended flexible pendants bearing alternate colored lamps of red, white and blue, while from each of the third story windows hung lamps of like colors, and, surmounting it all, making one huge pyramid of light, was a varicolored cluster of lamps in the cupola.

From beneath the ivy which climbs thickly round about the stone tower containing the gun room and telephone room, peeped forth also many red and blue lamps. The flag-pole, seventy-five feet in height, floated the Stars and Stripes, surmounted, not by the conventional eagle, but by a pin wheel five feet in diameter, containing over a dozen red, white and blue lamps and rapidly revolved by an eighth horse-power motor.

By five o'clock the guests began to arrive and they soon scattered about the place. The bowling alley, billiard room and tennis courts were taxed to their utmost capacity, but the engine room, with its two Edison dynamos, storage batteries, engines, and various regulating apparatus, proved to be a place of endless entertainment and instruction. The pumps operated automatically by Sprague motors and forcing water from wells twelve hundred feet distant, as well as the electrical dampers and other heat regulating apparatus automatically and electrically operated were thoroughly inspected. The electric organ in the hall entertained great numbers, while the phonograph in the "Den" with its popular vocal and instrumental music was the centre of a delighted audience. The idea of lighting carriages by electricity, recently mentioned as new and just accomplished in England, has been in operation on Mr. Johnson's several carriages for a number of years, and was also illustrated. The feature of the evening, however, was a grand display of Paine's Manhattan Beach fireworks, which were ignited by electricity direct from the lighting circuit, a suggestion from Mr. Johnson, and something, we believe, never attempted before.

The fireworks, some one hundred and fifty yards from the house, were ignited from the piazza by the turning of a small electric switch in the hands of Mrs. E. W. Little. A tiny electric bell at her side gave the signal that all was ready; the switch was then pressed and the rockets and bombs exploded.

The modus operandi, as conceived and carried out by Mr. Johnson, was as follows:—For skyrockets a battery (not electric) was constructed of six pieces of the one-inch tubing of the Interior Conduit Insulation Co.'s underground tube—another new application for this useful article. Upon the upper ends of each tube, which were cut squarely, were driven two French nails about one inch apart, and one side of each set of nails connecting with copper wire to one pole of the circuit (taken from an adjacent lamp-post) and the other side of each set to the other pole. Each pair of nails were connected by the simple winding about with a piece of fuse wire of small capacity immediately under the touchpiece of each tubed rocket. Accordingly each fuse was thrown directly across the line and all in multiple on the moment the switch on the piazza was made to close the circuit through a flexible cord across the lawn, thus effecting the simultaneous explosion of the rockets. The bombs and other pieces were touched off in a like manner, to the delight of an admiring audience. As the evening drew to a close all seemed reluctant to depart from this veritable fairy land.

THE ARC IN THE TREATMENT OF ORES.

A special dispatch from St. Paul, of July 17, says:—C. A. Daigh, of the Westinghouse Electric Co., has been in Tower, Minn., at the iron mines, for the last week, experimenting with electricity and iron ore in the interest of his company. He declares that he has discovered a process by which he can centre the rays of an arc light upon a piece of iron ore and thereby soften it to such a degree as to be able to work it with a greatly reduced amount of labor. It has not as yet become known with what success his labors have met.

A DESTRUCTIVE FIRE AT "195."

A fire of large proportions broke out in the Western Union building at 195 Broadway, this city, on July 18. James Larrissey, a wireman, who was on duty in the building, was the first to discover the fire. About the same time Mr. Tobin, night chief, noticed an odor of burning rubber, and on looking into a wire shaft leading from the battery-room to the operating-room, saw smoke very distinctly. This was five minutes before 7 o'clock. When Mr. Tobin discovered the smoke in the shaft and descended to the battery-room he was surprised at the great headway the fire had already made. The flames followed the wires to the room behind the great switch-board, and soon all the woodwork was burning. The fire leaped from table to table and to the window and door casings, and all efforts of the men on duty to suppress the burning by the appliances at hand were unavailing. The firemen were promptly on hand, and took possession of the building. The day force of operators were reporting for duty, but found it necessary to retire, and gathered in waiting at the Telegraph Club in Cortlandt street. Five female operators were led out of the building by the firemen. Some of the women in the restaurant were rescued from the roof by firemen of the life saving brigade. All above the sixth floor was destroyed. Carpets, papers, etc., on the fifth and other floors below, were soaked with water. The battery and storage rooms occupied the sixth floor.

The operating-room and the gallery devoted to the work of the Gold and Stock Company occupied the entire seventh floor, and the Associated Press and a part of the bookkeeping the entire eighth floor. On the ninth floor were the Western Union files.

The loss of the telegraph company is very large, and it will require a long time to replace the material. The large switchboard in the operating-room alone cost $50,000. The Associated Press lost instruments, typewriters, furniture, and all of its books, papers, and records dating from 1845, and a valuable refence library. This loss is irreparable. All of the material for a history of the growth of the press in America, contained in letterbooks and files, was destroyed and can never be replaced. The money value is estimated at $15,000. There is no insurance. Mr. William Henry Smith is personally a heavy loser by the destruction of rare books and papers, many of which cannot be duplicated. Among these were hundreds of rare pamphlets collected by Stevens in Europe, which Mr. Smith supposed were secure in this "fireproof" building. An extensive correspondence of great value was also consumed.

The telegraph company has divided its operating force among sub-offices at Twenty-third street, Jersey City, Brooklyn, and Weehawken, from which business will be done temporarily. Meanwhile quarters are being prepared at the old Baltimore and Ohio office at No. 415 Broadway, and part of the clerical staff has gone to the building at the corner of West Twenty-third street.

The United Press courteously tendered its facilities during the break, and the Postal Telegraph Co. secured a large part of the work. Owing to the interruption of the Western Union cable service, the Commercial Cable Co. has been crowded with extra business.

The loss to the Western Union Co. is estimated at $300,000. The company carries its own insurance.

The telephone was not used very much for press news, however, and officers of the Western Union said that they did not attempt to forward messages by means of it. There was, however, a great demand for it among persons who had imperative messages to dispatch, and it proved to be of great advantage for them. At some of the public telephone stations complaints were made that the wires were in such demand that it was extremely hard work to secure connections. Even at night the telephone company did a rushing business, and all its wires and operators were fully occupied.

Telephone wires were available to Boston and Philadelphia, in the evening. The demand from senders of messages was very great.

STEAM SUPPLY IN NEW YORK CITY.

W. C. Andrews, President of the New York Steam Company, and James W. Hawes, the counsel of the company, appeared before the board of health last week in opposition to the orders recently made by the board ordering steam to be shut off from certain sections of the company's plant within three days. Mr. Andrews argued that it had not been shown that the business of the company was either dangerous to life or detrimental to health. The business of the company, he said, amounted to $2,000 a day, between 3,000 and 4,000 buildings were supplied with steam, and 600 engines were furnished with steam by the company. To close these operations at short notice would cause great hardship and inconvenience, he contended. The board agreed to give the company another hearing this week. In the meantime, commissioner Gilroy has revoked all their permits for street opening, in spite of the protests of the company that injury is thereby inflicted on the public, or such portion of it as uses the company's product.

LEGAL NOTES.

LONERGAN vs. LAFAYETTE STREET RAILWAY CO., et al.

In the above case Judge B. W. Langdon, of the Indiana Circuit Court, sustained the demurrer to the complaint, and decided in favor of the electric railway. We give below an abstract of his decision:

The question presented arises on the demurrer for a want of sufficient facts to the complaint asking for a perpetual injunction against the railway company, prohibiting it from operating its cars by electric power and for damages for injuries suffered in consequence of the past use of that motor. The facts material to be noticed now are that the plaintiff is, and was before the construction of the defendant company's railway, the owner of a lot abutting on Main street near its western extremity in Lafayette, together with the iron works and blacksmith shop thereon, where he is and has been operating the same.

It is then alleged that neither the Common Council of the city nor the Board of Commissioners had any power to authorize the use of Main street, the bridge or highway adjoining for the purpose of operating a railway by electrical power, and the grants made by them are void, wrongful, and injurious to plaintiff's property rights and business. That the company claims the right and threatens to continue the use of its electric cars on Main street and bridge for 21 years, the time mentioned in its license. Prayer, as stated, for perpetual injunction, $500 damages, and general relief. It should be borne in mind that for the purpose of this case, according to the allegations of the complaint, that all the ordinary conditions usually found in the construction and operation of a horse railroad are present in the defendant company's railway, except those which relate to the matter of the motor power.

To determine whether a use of a street is without the original public easement, it is quite plain that the inconvenience complained of must be tantamount to a substantial impairment of the public use. In other words, that the use of the street is destroyed or converted into a new use, subversive of the original purpose. If the general public use and operation of the new motor are substantially consistent, they are homogeneous, and the locomotion of the cars by electricity or animal power is a mere matter of fact, and imports no substantial significance, because no new burden is imposed and no private property is taken in contemplation of law. The averments in the complaint relevant to this part of the matter are in fact not about the motor itself, but are rather about its manifestations, or the phenomena that follow from its operation. These manifestations are covered by the following allegations: That by reason of the propulsion of the cars by electric power they are driven much more rapidly than by animal power, and in passing over the street they make a loud, churning and pulsating noise, accompanied by a peculiar humming sound, and with the electric wire under the rail, produce constant flashes of electric light, especially at night and in damp weather, and are without visible means of locomotion. It is then alleged that these several facts cause fright to horses not long accustomed to these sights and sounds when approaching or are being approached by the cars, and they become uncontrollable and run away, and thereby frequent accidents occur. That the fright to such horses and the dangers incident to it have created apprehensions of danger upon the street, and it has become widespread in the community, and has the effect of driving trade and business from this street. The sum of the averments is that some horses not long accustomed to the movement of the cars by the electric motor become frightened and frequently run away. Does then the fact that some horses not long accustomed to the alleged manifestations show that there is a use of the street that is substantially inconsistent with the general public use of it? It is admitted, by implication at least, that horses will become accustomed to these sights and noises, and are tractable as usual. It comes to this, that some horses at first become so frightened until they are broke or familiarized with these sights and noises. It is plain that this inconvenience is temporary and not permanent, or insuperable, nor does it extend to the general public who are driving horses in the street, but is limited to those only who are using such animals. It is a fact and within the common knowledge of all who have observed the operation of these cars in the presence of horses, that the difficulties in their management are overcome in a comparatively short time, except in a few cases, and the streets are and can be used by the entire public passing over the street, in reasonable safety, and without any substantial impairment of the known legal right of any one. Effects not unlike these complained of are witnessed and have been since streets have been used for the movement of processions, parades, shows, passage of machinery or vehicles creating unusual sounds or noises or strange appearing sights, and it has never been considered that such a use was evidence of any additional burden or recognized as furnishing any legal basis for actionable wrongs where proper care was observed. It has been held that a change of motor can not be deemed a change in the use of the street. I do not think the averments raise the legal conclusion that there is such a substantial and permanent impairment of the use of the

street by the general public, that it can be inferred that an additional burden has been imposed; and if the defendant company has been authorized by law to use the motor complained of, the depreciation in the value of the plaintiff's property and business is not recognized by the law.

The plaintiff next maintains that the statute does not grant to the defendant company the right to use the electric motors to propel cars over the land in front of his lot, and that entitles to relief. The statute authorizing the chartering of street railways and prescribing their powers and duties, provides that a corporation may be formed by not less than five subscribers to the stock of any contemplated street or horse railroad company, for the purpose of constructing street or horse railroads upon and through the streets of the cities and towns in this state (ss. 4143 R. S., 1881; ss. 1 Act 1861, p. 75). The title of the act reads in these words: "An act to provide for the incorporation of Street Railroad Companies" The plaintiff insists and correctly, too, I think, that this act should be interpreted in the light of the circumstances and knowledge existing in 1861, when the act was passed in reference to the operation or locomotion of street cars. It is claimed that since street cars were then only propelled by animal power, it is reasonable to assume that the Legislature intended to enable companies organized under it to construct and maintain a horse railroad, and to exclude the use of any other motor. The paramount purpose of the Legislature in enacting the statute authorizing the use of a new and improved mode of travel in cities, was the public convenience. Especial regulations are imposed in reference to gradient and location, but nothing is directly said about the motor. The motor was not a controlling or noticed matter in the immediate purpose of the act. If the prime object was the accommodation of the local public, by the use of this sort of conveyance, how can it be reasonably asserted that this accommodation of the same public by the same way should be restricted to the use of an instrumentality which is only a subordinate means to the ultimate end in view, the accommodation or convenience of the public. If it is correct to say that public utility and convenience are the underlying considerations for establishing authority for the operation of street cars, it would seem that the propelling power should fall within the same consideration as the principal thing. In other words, that public utility or convenience should operate throughout and when it requires it, that the motor should be modified or superseded when not inconsistent with enjoyment of the public easement in the street by the general public, and in the absence of any declaration of a contrary intent it would seem rational to infer that such was the intent of the legislature. The act was passed at a time when it was a matter of common knowledge that mechanical devices were being daily discovered, and were practically applied in almost every department of public and private economies. The legislature was cognizant that science and skill was occupying wider and deeper fields of thought, and activities, and new discoveries were used wherever and whenever time, money, health and the convenience of the people required them. It would seem, in such a case, to be an inversion of the true intent and understanding of the legislature to say that all the useful invented appliances of the future should be excluded from public enjoyment, and that the horse or other animal should alone be utilized to propel street cars. The statutes speak of a street railroad in the enacting clause, and in the body of the acts, as street or horse railroads, and this language is sufficiently broad to cover a street railroad whether the cars are drawn by a horse or propelled by the power of an electric dynamo, and the defendant company is in the legitimate exercise of its charter power in using the same. In the view I have taken of the pending question, it is not necessary to examine other questions submitted. The demurrer to the complaint is sustained.

At the conclusion of the decision the plaintiff gave notice of appeal.

PATENT NOTES.

THE DE FERRANTI AND WESTINGHOUSE INTERFERENCE.

On appeal from the Examiners-in-Chief, the Commissioner of Patents has decided the interference between De Ferranti's application of April 18, 1887, and Westinghouse's patent of July 12, 1887, for improvements in electric converters, in favor of the latter, affirming the decision of the Examiners-in-Chief. Priority was awarded to Mr. Westinghouse under the ruling that "under the present British Statute, a British invention cannot be said to be patented within the meaning of sections 4,886 and 4,887 of the Revised Statutes, until the final act of affixing the Seal." The Westinghouse application was filed December 27, 1886. De Ferranti's English provisional specification was filed September 9, 1886. The date of sealing and issue of De Ferranti's English patent was February 15, 1887, subsequent to Westinghouse's application.

THE ELECTRIC LIGHT IN SAXONY.

A cable despatch from Frankfort, Germany, says that a syndicate has obtained a concession under which it will light electrically 168 Saxon towns and cities.

REPORTS OF COMPANIES.

CONSOLIDATED ELECTRIC LIGHT CO., OF NEW YORK.

The statement of the Consolidated Electric Light Company, of New York, for the period ending July 1, 1890, shows quarterly dividends for 15 months ending April 1, 1890, $126,271. From the income for the period ending June 30, 1890, there has been applied to the sinking fund for payment of bonds at or before maturity, $14,600; quarterly dividend of 1¼ per cent. payable July 1, $30,355. The total issue of bonds due in 1893 and 1895 was $325,000. There were purchased and carried to sinking fund, $141,800; bonds still outstanding, $183,200; total amount cash applied to sinking fund, $133,911; cash required under lease to be applied to sinking fund on June 30, $87,600; surplus, $46,311.

NEW YORK EDISON ILLUMINATING COMPANY.

General interest has been aroused in the news published first in these columns last week to the effect that Mr. John I. Beggs would resign the important position of vice president of the Edison Illuminating Company of this city, to assume new duties as manager of the Central District for the Edison General Electric Company. Since Mr. Beggs came to this city from Harrisburg, he has seen the business, then restricted to the Pearl street station, increase in a remarkable manner, so that there are now three main stations, the two new ones on West 26th and West 39th streets and the renovated Pearl street station, these in turn to be shortly supplemented by the big new station on Elm street, which is to take care of the region from Eighth street to the Battery.

The figures of the period from January, 1887, to July, 1890, bring out the growth very clearly. At the date named—the beginning of 1887—the local company's gross earnings were at the rate of $157,000 per year. Now they are not very far short of $750,000, or $2,000 per day the year around. There were then 500 customers; now there are 15 0. The number of lamps connected up was 12,489; now the number reaches 50,000, with the addition of 250 arc lamps, a branch of the business untouched in 1887. At the beginning of that year, the company did no motor business; now it furnishes daily 600 h. p. of current, and finds new work for motors every day. The number of employees has grown from 32 to no fewer than 532. Mr. Beggs has also installed 25,000 lamps in isolated plants throughout the city. A regular supply department, as large as an ordinary supply house, has been established and conducted profitably, and the company has done its own wiring with marked success. With such a showing as this, it need not be wondered at that the directors of the company have been reluctant to let Mr. Beggs give up his work here for the new sphere of labor in the West.

STOCKS AND BONDS.

THE SEDALIA, MO., ELECTRIC RAILROAD, LIGHT AND POWER CO. has increased its capital stock from $80,000 to $200,000.

THE GATE CITY ELECTRIC CO., of Kansas City, proposes increasing its capital stock from $10,000 to $30,000.

THE EDISON ELECTRIC LIGHT AND POWER CO., OF KANSAS CITY, has increased its capital stock from $100,000 to $150,000.

DIVIDENDS.

THE CHARLESTON, S. C., ELECTRIC LIGHT AND POWER CO. has declared a dividend of 75 cents per share.

THE CUMBERLAND TELEPHONE CO., Nashville, Tenn., has declared a quarterly dividend of 1¼ per cent.

OBITUARY—THOMAS E. QUINN.

Thomas E. Quinn, the oldest telegraph operator in the employ of the New Jersey Central R. R., died on Sunday, July 7, at Washington, N. C., where he had gone for the benefit of his health. He was manager of the Western Union office at Elizabeth, N. J., during the war, and had been in the employ of the company over thirty years. He was one of the best-known railroad and telegraph men in the State, and was fifty-five years of age.

OBITUARY—J. MARSHALL GLEASON.

We regret to announce the death, in his sixty-seventh year, of J. M. Gleason, the youngest brother of Mr. E. P. Gleason, of the well-known house of E. P. Gleason Manufacturing Co.

He died somewhat unexpectedly, of bowel and liver trouble, having been confined to his house in Brooklyn only a few weeks. He was custodian of the Brooklyn glass works of the concern, his son, Mr M. Wilfred Gleason, being the manager. The deceased was well-known to many electricians from having attended several of the conventions of the National Electric Light Association, and left behind him a large circle of friends, made by his fatherly, generous and charitable instincts displayed on many an occasion

in a quiet way. The funeral services were held at his residence in Java street, Brooklyn, and the burial took place on Saturday, July 12, in the Gleason family plot in Greenwood Cemetery. A large number of employees from the Brooklyn glass works and the New York factory and offices attended the funeral services.

METAL AND SUPPLY MARKET.

THE PRICE OF COPPER.

The course of prices for copper during the past year has been very different from that generally predicted after the collapse of the French speculation a year and a half ago. It was commonly believed that the enormous surplus stock accumulated at that time could not be marketed without breaking prices to very low figures for a somewhat protracted period. But the sharp rise of last October has been followed by a tolerably continuous increase. Consumption has been greatly augmented, the electrical demand alone serving to take up a great part of the Lake product. Prices in New York from July 11 to July 19 were as follows:

11	12	14	15	16	17	18	19
16.30c.	16.50c.	16.50c.	16.50c.	16.60c.	16.50c.	16 50c.	16.75c.

The prices 12th and 19th are those to which margins were called in the Metal Exchange. The other prices given are the rates bid. Holders asked .20 to .40 above these rates. The price July 19, 1889, was 11.90. Very little copper changed hands during the week.

ELECTROLYSIS OF THE MUSCLES.

In a recent number of the *Bulletin de la Société Belge d'Electriciens*, Dr. G. Weiss contributes a brief account of some interesting electro-medical investigations undertaken by him. That electrolytic effects take place at the electrodes where an electric current enters and leaves the human body is, says Dr. Weiss, universally admitted; but is the electrolytic action confined to these points? Dr. Weiss then points out how, when intermittent currents of the same strength are sent along the gastronemian muscles of a frog's leg, the contractions rapidly cease, and no amount of rest restores the muscles to their primitive condition. On the other hand, the duration of an alternating current does not perceptibly affect the contractions. This phenomenon points, therefore, to electrolysis of the muscle along the entire path of the current. Dr. Weiss then tested this theory as follows:—He took two vessels containing a one per cent. solution of chloride of sodium, connected them by a syphon filled with the same liquid, and passed a given current from vessel to vessel, using platinum electrodes. The experiment was then repeated with the two hind legs of a frog as connecting piece. The E. M. F. of polarization was considerably greater in the latter case than in the former. Dr. Weiss is of opinion that an electric current traversing a muscle gives rise along the whole length of its path to chemical decompositions, and that the products of these give rise in their turn to powerful secondary actions upon the substance of the muscles, which are rapidly attacked and destroyed. Microscopic examinations showed that the entire structure of a muscle was gradually altered by the passage of a current. Dr. Weiss then poured a strongly saline solution of gelatine, colored with well neutralized turnsol, into a U tube, and when the gelatine had solidified he poured in water colored in a similar manner. The turnsol not only changed color at the platinum electrodes but also at the surface, separating the gelatine and the water. With albuminous water the albumen was coagulated at the positive and completely dissolved at the negative surface of separation.

NEW ELECTRIC LIGHTING BIDS FOR NEW YORK CITY.

The new bids for street lighting from the electric lighting companies were opened last week by the Gas Commission. The companies' bids had twice been rejected as too high and calculated to make the cost of street lighting exceed the amount appropriated for this year. The new bids were: United States Company, 236 lamps at 35 cents a night each until Jan. 1 and 43 cents thereafter; the Brush Company, 165 lamps at 35 cents and 69 at 45 cents until Jan. 1, and afterward 165 at 43½ cents and 69 at 45 cents; the East River Company, 189 lamps at 35 cents to Jan. 1 and 43 cents thereafter; the Mount Morris Company, 109 lamps at 35 cents to Jan. 1 and then 43 cents; the Harlem Lighting Company, 104 lamps at 35 cents to Jan. 1 and 43 cents afterward. The members of the Gas Commission referred the bids to Secretary McCormick for tabulation and report. If they do not fit the appropriation, Commissioner Gilroy says he is prepared to go on and light the city with gas.

A LARGE ELECTRIC TRAVELING CRANE PLANT.

The Equitable Electric Railway Construction Co., of Philadelphia, Pa., are installing for the Southwark Foundry and Machine Works (builders of Porter-Allen engines), 5th street and Washington avenue, Philadelphia, Pa., what is supposed to be the largest electric traveling crane plant ever built up to the present time. There are two Sellers traveling cranes of 50 tons capacity, each running side by side in the foundry, which is about 400 feet long. The cranes run backward and forward over this entire distance, lifting heavy castings out of the sand. Each crane is being equipped with one 35 h. p. Sprague standard motor, and the two are supplied from a 50,000 watt Edison compound generator situated at one end of this building, driven by a Porter-Allen high speed engine. The current is conveyed to the motors through a Wheeler double trolley, running on a silicon bronze overhead line. Similar plants have been installed by the Equitable Electric Railway Construction Co., at the Pennsylvania railroad shops at Altoona, Pa., and Wm. Sellers & Co., Philadelphia.

ELECTRIC RAILROADS AT NASHVILLE, TENN.

At the recent meeting of the American Society of Civil Engineers, Prof. O. H. Landreth presented a paper on "The Electric Street Railway System of Nashville, Tenn.," in which he noted its remarkably rapid development and extension resulting from the change from mules to electricity. There are now 64 miles aggregate length of track, and over 100 cars. The overhead single trolley system was employed. The power developed was 670 nominal electrical horse power at 500 volts pressure. He described the plant, its details and operation, estimating by three different methods the total amount of power developed, and gave data of the effective power, cost of production, etc. In discussion it appeared that the operating expenses are very little increased, and the receipts are nearly doubled, both by expansion of the line and increased speed, which induces people to ride for pleasure. It was very much more economical than animal power.

In Washington, D. C., a new system is soon to be built having a main circuit and local ones with connections about 90 feet apart. This system has given good results on a 2,000 foot line, and is economical in construction, the feed-cable, trolley, wires, yokes, etc., being on top of the ties and very accessible.

WESTINGHOUSE ALTERNATING CURRENT MOTOR.

The Westinghouse Electric and Manufacturing Company are now making a new alternating current motor, which they claim, owing to its many advantages over any similar motor, is bound to become a great success. As it does not require any higher tension than the ordinary fifty volt alternating current, its usefulness makes it especially commendable for the operation of sewing machines and other minor requirements of power. The company has already received orders for five hundred motors.

INVENTORS' RECORD.

Patents issued July 15.

Alarms and Signals:—*Burglar Alarm*, J. H. Pruitt, 432,077.

Conductors, Conduits and Insulators:—*Conduit for Electric or Cable Railroads*, J. Lynch, 432,416.

Distribution:—*Means for Generation and Conversion of Electrical Energy*, A. De Castro, 432,022. *Induction Coil or Transformer*, C. E. Kammeyer, 432,050. *Regulation of Arc-Light Circuits*, D. Higham, 432,310.

Dynamos and Motors:—*Dynamo Electric Machine*, F. A. Perret, 432,169. *Commutator-Brush*, J. F. McLaughlin, 432,206. *Armature of Dynamo-Electric Machines*, O. A. Enholm, 432,387. *Armature*, E. Wagemann, 432,500.

Lamps and Appurtenances:—*Electric Arc Lamp*, E. C. Russell, 432,284. *Manufacture of Carbon Conductors*, A. de Khotinsky, 432,490.

Measurement:—*Electric Meter*, P. H. Korst, 432,053.

Miscellaneous:—*Water Conveyer*, G. W. Bailey, 431,542 (issued July 8). *Electric Stop-Motion for Warping Machines*, J. P. Haslam, 432,040. *Current Regulator or Rheostat*, O. Flemming, 432,131. *Coin-Actuated Device*, P. Kennedy, 432,163. *Electric Cigar-Lighter*, R. Graham, 432,197. *Electric Heater*, J. F. McLaughlin, 432,205. *Electric Switch*, J. F. McLaughlin, 432,207. *Electric Clutch*, J. F. McLaughlin, 432,209. *Apparatus for Detecting Short Circuits*, H. Redding, 432,215. *Electric Switch*, A. G. Frey, 432,234. *Current-Regulator or Rheostat*, G. B. Massey, 432,279. *Animal Clipper*, C. M. Palmer, 432,438. *Graphophone*, J. H. White, 432,462.

Railways and Appliances:—*Electric Railway*, R. M. Hunter, 432,019. *Trolley*, W. C. Miller, 432,063. *Electric-Railway Switch*, W. D. Swart, 432,095. *Electrically Propelled Vehicle*, R. M. Hunter, 432,136. *Electric Locomotive*, W. H. Knight, 432,142. *Means for Electric Locomotion* J. F. McLaughlin, 432,204. *Electric-Motor Car*, J. F. McLaughlin, 432,208. *Electrically Propelled Vehicle*, J. W. Henderson, 432,237. *Multiplex Electric Locomotive*, C. J. Van Depoele, 432,345. *Electric Car*, E. Wagemann, 432,501.

Secondary Batteries:—*Electrode for Secondary Batteries*, J. F. McLaughlin, 432,202.

Telegraphs:—*Telegraphic Relay*, J. M. Treber, 432,098. *Printing Telegraph*, W. W. Taylor, 432,453.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

THE ELEKTRON MANUFACTURING CO.

The Elektron Manufacturing Co. have recently added largely to their cash capital to enable them to handle properly their large and constantly increasing business, and they have doubled their manufacturing facilities twice during the last six months. They now occupy nearly all of the large new factory building, Nos. 79–81 Washington st., Brooklyn, N. Y. Their works are notable for fine machinery, whereby all parts are made accurately and interchangeably to standard gauges, and for the methodical and careful arrangement of their business. A fully illustrated description will be found in this issue of their new slow speed Perret motors.

FISHKILL CORLISS ENGINES.

The Fishkill Landing Machine Co., Fishkill-on-the-Hudson, N. Y., have just issued a new edition of their illustrated pamphlet relative to their well known Corliss engines, which embody a great many special features of excellence. Accompanying the description are a large number of references and several testimonials from users of the engines. The concern have also issued another edition of their boiler circular relating to their horizontal tubular boilers.

THE ELECTRICAL SUPPLY CO., CHICAGO.

The above concern has recently issued a very neat and effective circular relative to its Wirt lighting arrester, recently illustrated and described in our columns. The essential part of the Wirt arrester, which is broadly covered by patents, is a series of conducting plates wholly insulated from each other and having a very small space between them (from $\frac{1}{1000}$ to $\frac{3}{1000}$ of an inch), the discharge being made to pass over all the breaks in series. Each arrester is provided with terminal wires, to be joined to the line, and ground wires, thus avoiding screw connections.

EUREKA TEMPERED COPPER FOR ENGINE BEARINGS.

The Eureka Tempered Copper Co., of North East, Pa., have recently received the following letter from M. C. Connell & Co., of Hornellsville, N. Y.: "In reply to your favor of the 9th. inst. would say that we have been using your tempered copper for bearings on our engine for about six weeks, and we find it better than any we have before used. It is giving good satisfaction and we are well satisfied with it."

THE JEROME KIDDER MANUFACTURING CO.

The above company are recently in receipt of a number of testimonials as to their electro-medical apparatus. The following will serve as a sample :—

Office of Indiana Sanitarium, }
Brookville, Ind. }
Dr. S. P. Stoddard, Prop. } May 2d, 1890.

Jerome Kidder M'f'g. Co.,
820 Broadway, New York,

Please send by American Express one No. 5 Tip Battery with sponge electrode, etc., complete. * * * The first of these tip batteries I bought of you, I sent in 1873 to a friend in Omaha. The last was in 1888 or '84 when I had an office at West 45th street New York. Since then I have been persuaded into dry cell, chloride of silver and all sorts of others, two of which are now in my house, but none have ever done for me so much work and done it so well as your No. 5. I enclose draft on New York. Sincerely,

S. P. Stoddard.

ELECTRICITY IN JAMAICA, WEST INDIES.

A short time ago we published a very interesting article by Mr. A. Livingston Bogart on the electrical status of Bermuda. Mr. Bogart showed that that old British colony, with its new Halifax cable, was well in line with modern electrical work and ideas. Mr. H. C. Wilson, the Superintendent of Government Telegraphs in Jamaica, is now on a visit to the United States, and informs us that the "Isle of Woods and Springs" is also in the van so far as electricity is concerned. The telegraph service, which was established in 1879, now has 48 offices open, 8 more to be opened, 1,000 miles of line, and a staff of about 150 employés. The lines are worked on the single current system, with Siemens polarized relay and Daniell battery. The principal offices are Kingston and Port Antonio, the latter place being very busy owing to the enormous growth of the American fruit trade. There is also a good telephone system. Recently a local electric light company has been formed which has put in a fine Thomson-Houston plant, using good construction materials, such as Simplex wire, etc. The company is already an assured success. Several isolated plants are also being put in, and one has just been started at the new American Hotel at Constant Springs. It is now proposed to operate the street railway electrically. Jamaica will hold a Tropical Exhibition beginning January, 1891, when a good electrical display will be made.

APPARATUS BUILT BY BOYS.

Some most creditable work is now being done in the electrical classes of various educational institutions, and well worthy of note is some of the apparatus constructed during the past year by the students of the High School, Newark, N. J., under Prof. Sonn. The first of a series of prizes was taken by a fine Ruhmkorff coil, which has now been brought into daily use in the school. It is more powerful than that purchased for the use of the class, for which $40 was paid. Made by the same boy was a Holtz frictional machine, modelled after a machine worth $100, and described as being a very fine piece of workmanship. Among the apparatus handed in for competition were microphones, electro-magnets, galvanometers, electric motors, Leyden jars, and all kinds of electrical appliances. As there is no workshop in the school, most of the boys have been obliged to do their work at home. This is such a manifest disadvantage that Prof. Sonn of the Physics class is in hopes of having a shop, fitted with lathe and other appliances, built for the use of the boys. This is a most commendable lead. It is beyond question that a superior order of manual training has now become necessary, not only from the shop work of the technical school, but because of the intellectual development induced by doing and observing rather than merely studying. The practical teaching of electricity in schools will eventually be adopted, and its results will speedily be seen in the raising of the standard of electrical artisans and craftsmen.

THE SANDWICH ISLANDS CABLE.

John T. Waterhouse, the Honolulu capitalist, returned to this city yesterday, says the San Francisco *Chronicle* of July 10, from an extended Eastern visit. Mr. Waterhouse was one of the prime movers in the financial proposition of establishing an ocean cable between this city and Honolulu, and his Eastern trip was on business connected with the proposed cable. Mr. Waterhouse is evidently not at all pleased with the result of his Eastern trip, for in conversation last evening he said : "Business at the islands and the trade with this country are at a standstill. The recent elections at Honolulu and change in the cabinet and other administration offices have, of course, placed business men and capitalists on tenter-hooks, but nothing as compared with the effects of the tariff question."

Notwithstanding his failure to interest the leading Eastern capitalists in the Hawaiian cable proposition, Mr. Waterhouse said that while he had accomplished practically nothing there was still a large degree of progress in the movement from a new and outside source.

"English capital vested in American syndicates," said Mr. Waterhouse, "has been slowly absorbing many leading American industries, and the syndicates are now looking for connections outside of the United States, and more especially at Honolulu and in the Australian colonies. The colonies are developing very rapidly, and a telegraphic communication with San Francisco will soon be an absolute necessity. I dare not tell just what is being done in this matter, but rapid progress is being made."

Mr. Waterhouse intimated that an English syndicate was arranging to build a great ocean cable line from San Francisco to Honolulu and thence to Melbourne and other points in Australia.

AN ELECTRIC ROAD FROM BROCKTON TO BOSTON.

A special dispatch from Brockton of July 16 says :—The outlook for constructing a system of electric street railways, which will finally connect Brockton and Boston, looks more hopeful after to-day. The petition of the East Side street railway for a location in this city to the boundary lines of Abington, Holbrook, Avon and Easton was considered by the board of alderman, and granted, with the usual restrictions. Among those present at the meeting of the aldermen were the East Side directors, the selectmen of Randolph and several other gentlemen who would not divulge their names or business. It is said they represented New York and Boston capitalists who are interested in the proposed system of railroads. The plan proposed in connecting Brockton and Boston is to build the road as far as Neponset, where it will connect with the West End system. There is an electric road in Quincy already, and one is to be built this summer in Randolph. There will be 15 miles of road built in this city. The prime mover at the head of this scheme is said to be one of the car motor concerns, whose object is to have a system constructed which will be open for the inspection of capitalists in other towns and cities. The East Side road has asked for a location in Avon, and others are demanded in Holbrook, Randolph, and possibly Braintree.

Long Branch, N. J., is agitating the subject of an electric road and hopes soon to get one, although the first application, by the Monmouth Electric Railroad Co., for a borough franchise, was refused last week.

THE WESTINGHOUSE ELECTRIC COMPANY'S RAILWAY WORK.

The first electrical equipment turned out by the Westinghouse Electric Company was put in operation on the Pleasant Valley road, on July 4th, and has been in daily operation ever since, without a hitch of any kind, in marked contrast with motors of less substantial construction.

The motors heretofore made for street railway purposes have generally required the use of wrought-iron pole-pieces, and a necessarily complicated construction. The motor made by the Westinghouse Electric Company, however, does not require wrought-iron pole-pieces. Its principal part is a strong and rigid cast-iron frame, which carries the bearings and pole-pieces. The gear-wheels and pinions have broader faces than those heretofore made; in fact, everything about the apparatus indicates strength and reliability. The caps for the bearings and the pole-pieces are arranged so that the armatures, coils and field magnets can be conveniently removed for the purpose of repairs, and there is used an electric governing apparatus of novel construction which seems to possess advantages over all forms heretofore tried.

To protect the gears from rapid wear, and to deaden the sound, it is proposed to surround the gear-wheels by a cast-iron dust-proof box, which will contain a sufficient amount of oil to keep the teeth of the gears constantly lubricated. This lubrication will lessen the friction and the noise, and the box which will surround the gears will so far deaden the sound as to make it unobjectionable. The noise made by apparatus which has been in use a considerable time, and which has become badly worn, has grown into a nuisance, and street railway officials generally are expressing the hope that some way may be found for transmitting the motion from the motor to the car axle without the use of gear-wheels, for the reason that they are not only troublesome on account of the noise, but because the rapid wear involves heavy expenses for repairs.

ARMINGTON & SIMS ENGINE COMPANY.

We have received from the Armington & Sims Engine Co. a beautiful album of views of Providence, R. I., and of the leading manufacturing establishments of that rich and busy city. The first view shown is that of the Armington & Sims Works, a handsome and substantial collection of factory buildings commodiously grouped for the production of engines known around the world, and that have won everywhere the highest encomiums for American mechanical genius and skill.

THE MEN WHO SUCCEED.

Young mechanics make a very egregious mistake, says the *Builders' Gazette*, when they begin to think that they do too much for their employers when they work a few moments overtime to complete a small task they are performing, just at the time the whistle blows to quit work. More young men have been kept from receiving an advance in their wages from this than from any other known cause.

Employers watch the movements of young men very closely, and the least little thing oftentimes places them in an unfavorable light before their employers. It is the young man who studies the interest of his employer, and is not afraid to give him a few moments, that gets the rapid advancement. He is the young man selected when there are any favors to be granted.

I can tell in twenty minutes in any workshop the young man who is most likely to succeed in his trade. He is the last to leave his work, and is always prompt in beginning it. These fellows that drop their work at the moment the whistle blows are always the ones that the employer is ready to discharge when business gets a little slack.

The young man who takes the interest of his work at heart, and his employer into consideration, is very rarely laid off in slack times.

HARRIS-CORLISS ENGINES FOR LOWELL.

The electric light company at Lowell has received the new 500 h. p. engine made by the Harris-Corliss Co., of Providence, and the foundation for it and those of the boilers will be completed at the new plant this week. The new plant will be ready for operations next month. Four new boilers will be put in.

NEW ENGLAND TRADE NOTES.

The Standard Electric Co. of Vermont, have just shipped to John M. Sharpless & Co., of Chester, Pa., a 200 incandescent light plant, ordered through their Philadelphia office.

President H. A. Pevear, of the Thomson-Houston Co., with Mrs. Pevear, his son, H. T. Pevear, and wife, and Mrs. T. F. Bancroft and daughter, starts this week on a trip to Alaska.

Paine & Francis have received the order to furnish two Edison 500 light dynamos, for the new Exchange Building on State street, which the New England Wiring and Construction Company are at present fitting up with the "interior conduit" system.

The Electric Mutual Insurance Company is about to appoint a new inspector, the volume of its business making such action necessary. This week, too, a meeting of the stockholders will be held to increase the number of directors to 15, several prominent electricians to be added to the present board.

The New England Wiring and Construction Co. have received the contract to wire the Chamber of Commerce, Central Wharf, Boston, for over 1000 lights capacity. The "interior conduit" will be used throughout, and there will be no gas piping whatever in the building, which will be connected to the general Edison system of Boston. They are also at present wiring for about 225 lights the Bradley building, on Tremont street, which also will take its current from the Edison station.

The Evans Friction Cone Co. have received orders to equip the new station of the Leavenworth Electric Light Company, of Leavenworth, Kans., with their frictional system of driving dynamos. The station has been especially designed for using the Evans system, and will consist of two compound Ball engines, five Thomson-Houston arc machines, and three Heisler dynamos. The shaft on which are the pulleys to drive the dynamos, will be coupled direct to the engines. The Evans Co. are also in receipt of an order to equip two Thomson-Houston H. I. dynamos at the Cocheco Mills, Dover, N. H., with their frictional system of driving.

Pettingell, Andrews Co. have secured the agency for New England, New York State, Pennsylvania and Eastern Canada, of the "Tested Fuse Wires," tested by the Massachusetts Electrical Engineering Company. These fuse wires and American Safety fuses are made of the best material and tested and guaranteed by the Massachusetts Electrical Engineering Company, and are meeting with great success since their introduction a few weeks ago. All orders from the above mentioned States must be sent to Pettingell, Andrews Company, and new agencies for other States will soon be made.

WESTERN TRADE NOTES.

Mr. G. R. Noyes has accepted the position of manager of the Chicago Electric Club. Mr. Noyes is a graduate of Harvard and the management are to be congratulated on their selection.

Mr. J. C. Liggett, of the Milwaukee Edison Company, was in town this week investigating the various systems and arrangements of the electric lighting plants in the Chicago theatres with the view of adopting the best points embodied therein in a similar plant he is about to install in Milwaukee.

Mr. J. L. Barclay has removed the offices of the Westinghouse Electric Railway Company from the Rialto building to a handsome suite on the ground floor of the Pullman building. Their new quarters are very roomy, and are being handsomely and tastefully fitted up.

Mr. G. A. Edward Kohler, Western manager of the Eddy Electric Motor Co., of Windsor, Conn., has just sold a 3-horse power motor to Ederer & Co., 151 Wabash avenue, where it will be employed to operate machinery for manufacturing fishnets. The electric motor is slowly but surely finding its way into every possible class of manufacture.

The Electrician's Time Co. is the name of a new company just organized in Chicago to do a business in watches, diamonds, jewelry, etc., principally amongst electrical men. Their offices are located at 167 Dearborn street, room 416. Very special inducements are held out to electricians and all should patronize the new company. Mr. L. W. Collins, the late genial manager of the Electric Club, represents the company.

The Knapp Electrical Works are doing a brisk trade all the time in their various specialties. In addition to their Grimshaw wire they are selling a large amount of the American Electric Works line wire for pole work. The Knapp annunciators still find a ready market as always, and quite a number of electric motors for ventilating purposes and other classes of work are being sold.

The Sunbeam Incandescent Lamp Co., cor. Randolph and Canal streets, are taxed to their utmost capacity turning out their lamps. These lamps are manufactured to fit any socket, have a remarkably long life and do not blacken. The efficiency is also high, and there is no diminution of the rated candle power during the whole life of the lamp. Mr. Cook, the treasurer of the company, has just returned from a trip, and has brought away with him some nice orders.

The Electric Merchandise Co. are doing a remarkably large business in electric railway supplies, to which they give their undivided attention. They are bringing out new and valuable specialties in this class of work all the time and their devices are meeting with widespread adoption by electric railroad men in all parts of the country. Their latticed iron poles, which are manufactured specially for them by the Wisconsin Bridge and Iron Company, are in especial demand and meet a want which has long been felt.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, JULY 30, 1890. No. 117

I have examined piles of broken rails, links, pins, wheels and axles and have never been able to discover a fracture in good honest material.—William S. Huntington.

THE WORK OF THE STREET CARS.

According to figures compiled recently there are now nearly 9,000 miles of street car track in this country and Canada. The figures furnished us by the *Street Railway Journal*, in response to an inquiry, are as follows, being derived from the latest returns received from street railway companies :—

Miles of Horse Railway	5,902½
" " Electric	1,753
" " Dummy	556
Cable,	441
Total mileage	8,652½
Number of Electric Roads	264
" " Cable "	44

It will be seen that the electric roads begin to play a very important part in the street railway field, exceeding 25 per cent. of the mileage and of the number of roads, which are not far short of 1,000. When we remember that street railways have been running since about 1832, and the electric roads, as a practical commercial service, since 1885, it will be seen that electricity has developed and conquered at an amazing rate.

It is no wonder that the problems of street railroad work are so attractive to electrical inventors and electrical engineers. They begin to realize the magnitude of the field, its possibilities, and the fact that it is theirs in a peculiar and special way. It is also a good training school for the heavier work that awaits beyond in operating many of the present steam railroads.

The work of the street railroads in the urban transportation of our people is enormous. In St. Louis it has been found that the whole population is carried 110 times a year by the street cars. In the State of New York the surface street railways, 91 in number, carried 368,496,648 passengers during the year ending September, 1889, or the whole population of the State fifty or sixty times. If we added the 217,000,000 of the elevated roads, it would make the population of the whole Empire State ride not less than eighty or ninety times a year in the street cars. Probably such high ratios do not apply over the whole country, but the figures are still very striking, even if minimized. There are slightly over 29,000 street cars, open and closed, in America. If, say, 18,000 of these are in daily commission and carry no more than 200 passengers each, the total number of passengers is not less than 1,314,000,000 per annum. This would give every inhabitant of the United States about 20 car rides a year.

Evidently street railway work is rapidly assuming gigantic proportions, and as it grows it opens up a larger and larger area for electrical engineering and electrical productions.

COST OF ARC LAMP TRIMMING.

One of the regular items of expense in operating an arc station is that of lamp trimming. As a general rule, and perhaps universally, the carbon trimmers are paid at the rate of about $2 per day, and each man has so many lamps assigned to his care. The general manager of a large plant in the Southwest informs us, however, that he has tried the performance of trimming duty on a piece-work basis. At first they paid their trimmers 2½ cents per lamp, so that the men made as much as $75 to $90 per month, although the circuits are very long. Since the middle of May, they have reduced the rate to 2 cents per lamp, the men still making as much as $65 per month. Each man, it will be seen, looks after more than 100 lamps per day.

A disadvantage of this method is that the men are hardly likely to take time to give the lamps the care they require, the trimmer being more anxious as to the number of the lamps than as to their efficient burning. On the other hand, the men, since they get so much for each lamp on their "beat," are anxious to secure new customers, and will readily go out of their way to secure additional business for the station. We think the subject an interesting one, and would be glad to have other data or expressions of opinion from our readers.

CHEAP CONTRACT WORK.

There is no denying the fact that cheap and dishonest competition has cut much of the interior wiring business into pieces, so that reputable contractors often do not care to bid on work. It is true the lighting wires are subject to inspection, but the rates asked are so low sometimes that one knows immediately that, inspection or no inspection, either the purchaser will "get left" or the contractor will shoulder a heavy loss. In ordinary work for bells, annunciators, alarms, etc., where conscience is not kept on the alert even by fear of the inspector, the work is frequently disgraceful. If it were plumbing, the architect knows that he would have to deal with a board of health

or with a nervous buyer whose sense of smell had been abnormally developed by the reading of sensational hygienic literature. But wiring—the lowest bid will win the day. This is not as it should be, and until architects are themselves able to judge of the quality of the work and of the goods used in the installation, they should call in a trustworthy expert or engineer, whose modest fee for examination will be recouped many times over in the solid satisfaction enjoyed by the occupants of the property. The subject is one of general interest to the electrical profession. There is certainly room for better work, and better prices for it, and the effort should be made to raise the standard in both respects.

LIGHTNING PROTECTION.

THERE is perhaps no more anxious time for the central station manager than when he sees a thunder storm approaching, with the consciousness that the entrance of lightning into the station may ruin part of his machinery, if it goes no further to entail more serious destruction. The lightning protection of central stations has in fact been the constant study of not a few electricians and inventors of eminence, and that there is still room for study and improvement is evidenced by the frequent appearance of new devices designed with this object in view. Quite recently our columns have contained descriptions of apparatus of this nature in which the object aimed at was the elimination of all self-inductive resistance from the circuit on the one hand, in order to present no obstacle to the path of the oscillating discharge; while, on the other hand, we described a device in which self-inductive resistances were purposely inserted in order to force the discharge to take an easier path to earth. In our last issue we presented another modification, in which the purpose aimed at is not only to eliminate all self-induction, but all non-inductive resistance as well. Mr. Holcombe, it will have been noted, has accomplished this by the connecting to the line direct a device possessing a potential of its own in opposition to that of the line, but offering little or no resistance to the passage of a lightning discharge.

Small Arc Lamps.

WHILE at the outset arc lamps were employed to a considerable extent for interior illumination, their use is at the present time confined almost exclusively to outdoor illumination except in cases where large interior spaces are to be lighted, and where the height of the ceilings permits of the even distribution of the light. It has often been remarked, however, that an arc lamp of small candle power ought to find a large field for application for interior illumination, and it is indeed strange that efforts in the past have not been made or have not been successful, if made, to produce a lamp of this nature. We believe that some attempts, with fair success, have been made abroad, but up to the present this field seems to have been entirely neglected in this country. We are glad to note, therefore, the appearance of a lamp designed for such a purpose, and which we describe in another column. With good mechanism and good carbons, so as to insure a steady light equivalent to 150 or 200 candle power illumination, there is no reason why such a lamp should not come into extensive use, especially on the score of economy.

Electric Metal Working.

Now that electric welding, pure and simple, has attained a firm foothold in the arts, we see springing up around it, and as a direct result of it, a variety of most valuable and interesting processes worked out by Prof. Thomson and his associates. Among these we describe in this issue a process for case-hardening, devised by Prof. Thomson, in which the high heat produced by the current is employed to effect the deposition of carbon from a hydro-carbon gas surrounding the piece to be treated. This process will be recognized at once as analogous to that employed for the flashing of incandescent lamps in order to obtain uniformity in the filament. In the present instance, however, the body upon which it is deposited combines with the carbon to form a steel coating. Mr. Lemp's process of electric swaging seems also destined to a wide application, not only on account of the nicety with which the operation can be performed, but equally on the score of its economy. It is safe to say that we have by no means reached the end in this work, which indeed seems without limit.

Developing the Phonograph.

A BRIEF article elsewhere in our pages gives a few interesting details as to the later development of the phonograph. It appears that 8,000 phonograph or graphophone machines are now in use, and that the number is rapidly increasing, as it is likely to do when a single firm finds employment for as many as 16. After ten or twelve years of telephonic exploitation, there are well over 400,000 telephones in use, and since the newcomer will prove far more generally serviceable, there is no reason for doubting that after a like period not many short of a million phonographs will be at work. The phonograph is a much simpler piece of apparatus to master and run than the sewing machine, and of its immense convenience we can speak from personal knowledge and experience. A feature that gives it special interest to electrical people is its dependence upon electricity as a motive power. Not a little ingenuity has already been shown in supplying motors and batteries for its operation, and it is obvious that further uses for electricity will be found as new fields for the phonograph are opened up.

Mercury Thermal Cut-Outs.

As a method of protection from abnormal currents, fusible cut-outs have found wide application, probably as much on account of their simplicity as for any other reason. When applied to the protection of delicate instruments, however, the difficulties encountered in drawing down a fusible metal, on account of its lack of tenacity, and also from its extreme fragility, limit its use. To avoid this, Mr. Stephen D. Field has applied the mercury cut-out in an ingenious manner, by which not only is uniformity and strength obtained, but the cut-out is saved from destruction, and, upon the cessation of the abnormal current, immediately assumes its former guarding functions. The cut-out shows itself to be quite satisfactory in its operation under severe conditions.

THE RIES ELECTRIC TRACTION-INCREASING SYSTEM.

We have recently devoted considerable space to the discussion of the increased adhesive effect produced between driving wheels and rails and other metallic surfaces when traversed by an electric current under given conditions. Among the contributions upon this interesting subject, we have had the pleasure of describing in detail[1] the important results obtained by Mr. Elias E. Ries, during a series of original investigations and experiments extending over a considerable period, in the direction of applying this method of increasing tractive adhesion to steam and electric railway locomotives.

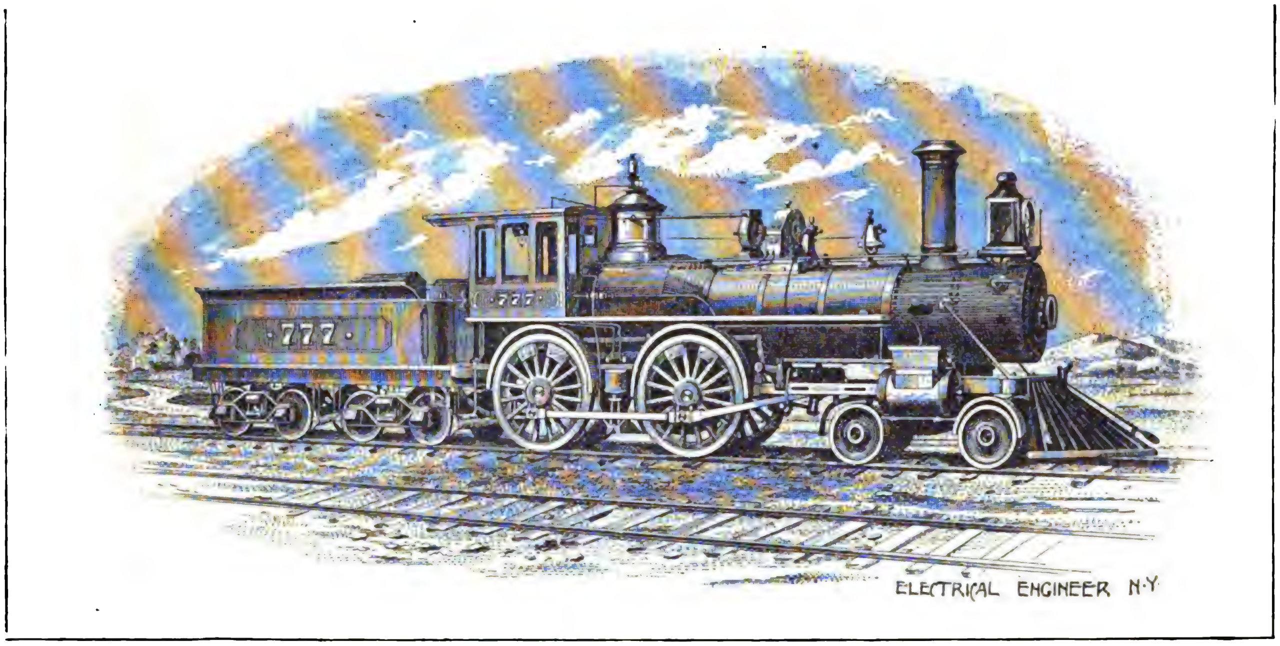
It will be remembered that in this system of electrically increasing traction as developed and practiced by Mr. Ries, a low tension quantity current is made to flow through a local circuit of almost negligible resistance, of which circuit the driving wheels and that portion of the track rails immediately below and between them form the principal part. This current produces a slight local heating or incipient welding effect at the points of contact between the wheels and rails, which is practically instantaneous in its action, and brings about a decided increase in the coefficient of friction between the opposing metallic surfaces.

Practical interest in the subject has recently been awakened among railway men by the exhibition of working models of this invention at the annual meetings of the Association of Railway Telegraph Superintendents[2], and of the American Railway Master Mechanics Association[3], held at Niagara Falls, N. Y., and at Old Point Comfort, Va., respectively, on June 18 and 19, 1890, at which the new method of increasing tractive adhesion met with considerable favor, the models exhibited showing an increase in traction due to the current of over 200 per cent. Preliminary tests of the invention, as applied to steam locomotives in regular service, have been very successful, and this, together with the favorable reports of experienced railroad officials who have investigated the system, has recently led to the organization, in Baltimore, Md., of the Ries Electric Traction and Brake Co., with a capital stock of $2,000,000, for the purpose of further developing and introducing the same.

1. The Electrical Engineer, June 4, 1890, page 432.
2. The Electrical Engineer, June 25, 1890, p. 511.
3. The Electrical Engineer, July 2, 1890, p. 18.

We are enabled this week to present to our readers, through the kindness of this company, a perspective view showing the general appearance of a steam passenger locomotive equipped with their electric traction-increasing apparatus, and we hope soon to be able to make public the results of the new series of tests that we understand are now in progress on the Baltimore and Ohio Railroad.

Referring to our illustration, it will be seen that the traction-increasing current is generated by a small alternating current dynamo driven by a rotary engine supplied with steam from the locomotive boiler. The engine and dynamo are mounted upon a common base secured to the boiler in the position formerly occupied by the sand box. One or both pairs of driving wheels are electrically insulated from the body of the locomotive and from each other by the use of special insulation surrounding the driving box and side rod brasses. The insulation so far employed has proven itself fully capable of withstanding the exceptionally severe strain to which it is subjected, and tests made after several months of continuous service have led to its permanent adoption for this class of work.



The Ries Electric Traction-Increasing System.

Electrical connection with the two pairs of drivers is maintained by means of peculiarly constructed brushes bearing upon brass sleeves secured to the central portion of each driving axle. These brushes are connected, by means of heavy stranded copper conductors, with the source of low tension current, which in the case illustrated is a transformer (not shown) placed in proximity to the main driving axle. A type of machine is now about to be used, however, which generates directly the low tension quantity currents required. As the resistance of the traction-increasing circuit is practically constant under given track conditions, the flow of current is usually regulated by varying the electro-motive force, which, on account of the low resistance of the circuit and multiple connection of the driving wheels, can be kept very low. The current density at the points of contact between the driving wheels and rails can be varied at will, according to the percentage of increased adhesion desired, the usual range being from 500 to 2,500 amperes.

It is proposed to use part of the current generated by the dynamo, either directly or indirectly, according to the type of machine employed, for the operation of electric locomotive and train brakes, electric headlight and train lighting, etc., in addition to its use for increasing traction. The dynamo is generally kept running at a slow rate of

speed when not otherwise employed, and is so constructed as to respond promptly and automatically to any demand that may be made upon it within the limits of its capacity.

Experiments already made upon a large scale have shown that by this method it is possible to increase the tractive adhesion of locomotives fully 25 per cent., thus enabling them, with a saving of fuel, to haul a largely increased load, to mount heavier grades, and to descend the same under perfect control and without the skidding of wheels. Besides this, it will enable railroads to haul, with their present engines, much longer trains than they can now do, thus not only increasing the carrying capacity of the road, but saving largely the wear and tear upon tracks and bridges that the use of heavier engines for this purpose would entail. It will likewise enable both passenger and freight locomotives to make better speed and to maintain schedule time notwithstanding ordinary unfavorable conditions of the track due to the weather.

A recent report of a large railway shows that an increase of *one-fifth of one car* per train brought an increased revenue of over $50,000 in six months. It is needless to say, therefore, that if the claims made by the Ries Electric Traction and Brake Co. for their traction-increasing system are even partially realized in practice—and the experiments already made by Mr. Ries go to indicate that these claims are entirely within the mark—the increased earnings to railroads from the use of this invention would be simply enormous, to say nothing of the operating and other advantages to both steam and electric railways that would result from its adoption.

McDOUGALL'S ELECTRIC CAR MOTOR.

In our last issue we described the electric car now being constructed by the McDougall Electric Co., after designs by Mr. Wm. M. McDougall. The latter gentleman has, however, devised still other means of construction, and among them is one in which the motor revolves with the

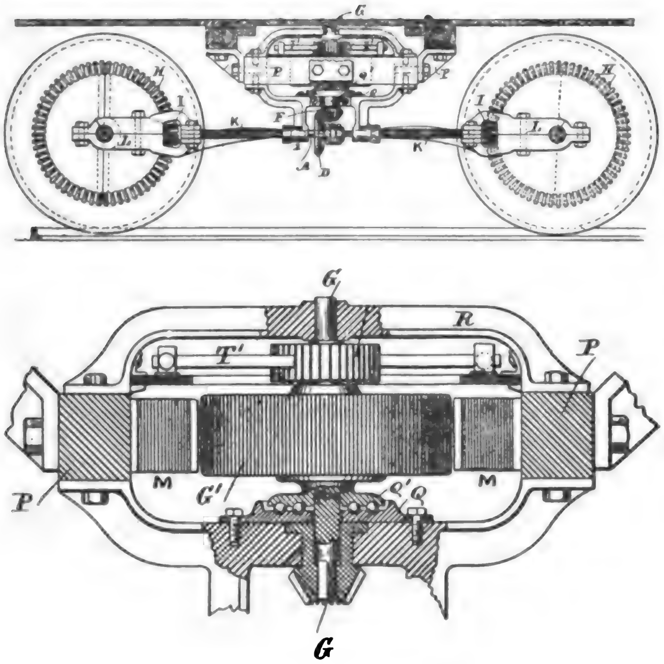


Fig. 1.—McDougall Electric Car.

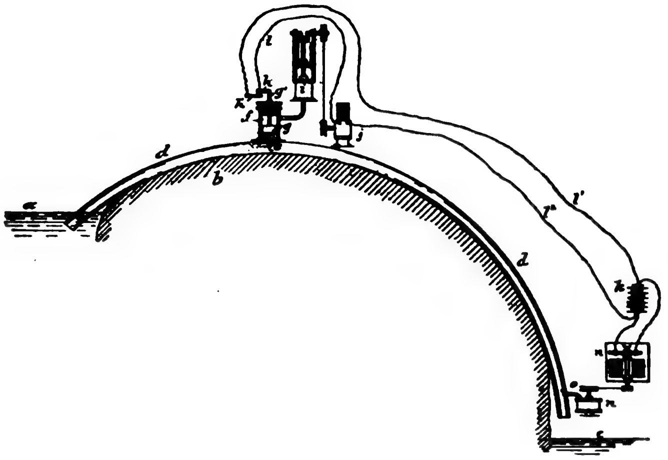
shaft placed vertically and connected to the axles by bevel gear. The manner in which this is carried out is shown in the accompanying engraving, Fig. 1, which shows a side elevation of the car truck, Fig. 2 showing the motor enlarged and in section. As shown, the shaft K is coupled to the short shaft A, supported by bearings upon the frame of the motor and between these bearings is the bevel gear D meshing with the pinion F. The bevel gear-wheel D and sleeve are slipped endwise upon the shaft A by lever and fork, and when the wheel D is in contact with the pinion F the car will be propelled.

The motor is provided with field-magnets M, supported by the main frame P of the machine and the beams of the car. The armature-shaft G passes into the pinion F, and in order to allow the armature and shaft to be lifted out, a square or key is placed at the lower end of the shaft to connect the same to the pinion F, and this pinion has a tubular hub



The Electric Siphon.

and flange within the frame for holding the pinion in position when the armature-shaft is withdrawn.

In order to lessen the friction Mr. McDougall makes use of a concentrically grooved plate Q, and a similar plate Q′, fastened upon the armature-shaft with steel balls in the concentric grooves for supporting the weight of the armature. The upper end of the armature-shaft is supported by a removable cross-bridge R, bolted to the main frame, and having a central bearing for the armature-shaft, so that the armature can be lifted out when this bridge is unbolted and removed, and to facilitate this operation a trap is provided in the floor of the car, so that by lifting or swinging the same inside access is given to the motor. The commutator and brushes being at the upper end of the motor, are easy of access for cleaning or repairs by simply lifting the trap.

AN ELECTRIC SIPHON.

The application of the siphon for the conveyance of liquids from a higher to a lower level is an old one, but when it is attempted to apply it on a large scale difficulties are encountered due to the accumulation of air in the upper end of the siphon, which stops the flow. In order to avoid this, Mr. George W. Bailey, of Brooklyn, N. Y., has recently devised a method which is illustrated in the accompanying engraving. Here the siphon pipe *d* dips at one end into the water *a* and extends upward over the bank and downward to the lower level *c*. *e* is a hole connecting the interior of the pipe at the top of the bend with chamber *f*. Within this chamber is placed a float *g*, which is connected by the stem *g′*, with one of two electrical contact points *h h′*, so that when the float *g* falls the contact will be made between these points, and when the float *g* is raised the contact will be broken. *i* is an air pump arranged to exhaust air from the bend of the siphon-pipe and *j* is an electric motor arranged to drive the air pump.

A storage battery *k*, is connected with the electric motor by the wires *l l′ l″*, so that when the current is closed in those wires the electric motor *j* will be operated to drive the air pump so as to exhaust the air from the bend of the siphon. The wires *l* and *l′* are connected, respectively, with the contact points *h* and *h′*. Current is generated by means of a dynamo machine *m*, driven by a turbine wheel *n*. The water for driving this turbine wheel is taken near

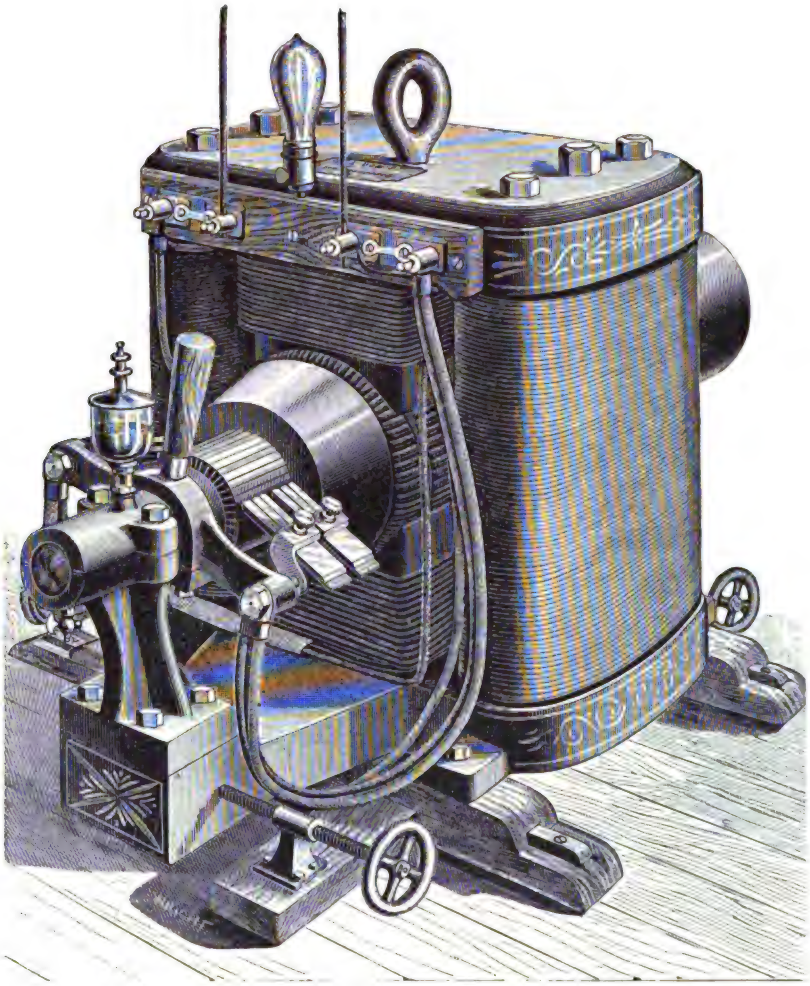
the lower end of the siphon pipe from the stream of water falling within, the siphon pipe *d* being tapped by a branch pipe *o*, leading to the turbine for that purpose.

The operation will now be readily understood :—When the siphon pipe is in perfect operation, the water will rise up in the chamber *f* sufficiently to raise the float *g* and break the current of electricity by separating the contact points *h* and *h'*. Under these circumstances there will be no current to drive the electric motor *j*, and consequently the air pump will not operate. As fast as any air accumulates in the bend of the siphon pipe, it will rise up into the chamber *f*, and the level of the water will fall therein until the float has descended far enough to bring the contact points *h* and *h'* together, so as to close the current. This will start the electric motor *j* in operation so as to drive the air pump and exhaust the air from the chamber *f*. This operation will continue until the air has been exhausted sufficiently to raise the level of the water and with it the float, so as to separate the contact points *h* and *h'*. In this manner the air pump and electric motor will be required to operate only to a very slight degree, in order to keep the bend of the siphon free from the accumulation of air. At the same time an ample charge will be maintained in the storage battery *k* by the continuous operation of the turbine *n* and dynamo *m*.

Mr. Bailey believes that with an arrangement similar to that described above, many natural waterfalls might be availed of for power, in many cases where sluices or tunneling would either be impracticable, or too expensive, especially as natural waterfalls usually occur in rocky places, where the conditions that are unfavorable to almost every other agency, still admit of the use of electricity.

THE LOOMIS INCANDESCENT DYNAMO.

Constancy of potential on incandescent circuits has long been recognized to be essential to long life in incandescent lamps, and dynamo builders have made this quality in their machines subservient to almost every other. To attain this object—that is, constant potential at varying loads—the Eureka Electric Company, of this city, have brought out a machine designed by their electrician, Mr. O. P. Loomis, in which compound winding is applied in a most effective way. The machine, which is illustrated in the accompanying engraving, is of the consequent pole type, but instead of following the usual practice in compound wound machines, Mr. Loomis places the series coils directly upon the pole pieces. In this way their action is intensified by their being brought as close as possible to the armature. Another feature of the series coil is, that a wide copper strip is employed instead of wire, the object being to obtain as low a resistance as possible. Mr. Loomis finds that the winding and insulation of such a copper strip can be very easily performed and that it is quite as economical as copper wire, as regards cost, if not more so. The latter would have to be very heavy to carry the current and the turning of the corners would involve difficulties which are absent in the copper strip.



The Loomis Incandescent Dynamo.

The result of the compounding is that the potential of the machine remains practically constant between full load and one lamp, as we had occasion to note in a recent trial.

The machines are built in sizes varying in capacity from 25 lamps to 750. The 600 light machine has a current output of 400 amperes, and its armature is wound with a cable consisting of seven No. 10 wires, and having a re-

sistance of .009 ohm. This cable is in one continuous length and tapped by copper strips connected with the commutator. The shunt coils consist each of twelve layers of No. 10 wire and have a resistance of 19.5 ohms. The series coils consist of 6 turns of copper strip .065 inch thick and 5 inches wide, wound on each pole piece, and have a combined resistance of 0.0013 ohm. The machine is designed to give 110 volts at 950 revolutions, and weighs 5,600 pounds. All the mechanical as well as the electrical details have been well worked out, and the machine presents a very neat and compact appearance.

ARC CIGAR LIGHTER AND TABLE LAMP.

The convenience and cleanliness accompanying the application of the electric current for heating purposes has already found many uses for it, among which the electric cigar lighter is now a familiar object in many cities. Heretofore this class of apparatus has embodied a construction involving the heating of platinum or german silver wires, but a departure in this respect has recently been made by the substitution of the arc light. This has been carried out very neatly in apparatus shown in the accompanying engraving. The cigar lighter consists in fact of a small arc lamp, the mechanism of which is hidden in the ornamental base. By pressing the button shown, the arc is started, and the mere application of the cigar end at the arc serves to light it uniformly. The lamp consumes only half an ampere of current at an E. M. F. of 50 volts—that is, the electric engery equivalent to an incandescent lamp, and as it is lighted intermittently, the cost for current is but trifling, not exceeding, it is claimed, 15 cents a month; while the avoidance of all burnt matches, the trimming of lamps and other cigar-lighting devices gives it a distinct value. The lamp is adapted for both

An Arc Cigar Lighter and Table Lamp.

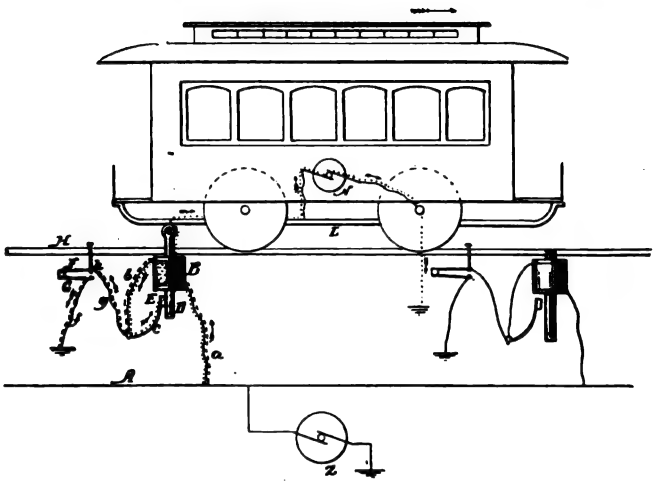
continuous and alternating and for arc or incandescent circuits. The carbons are calculated to last one month with ordinary use.

The lamp can be readily transformed into a table lamp for the studio, drawing-room or office, with the addition of an ornamental shade. It gives a light equal to 180 candle power, equivalent to more than ten 16 c. p. lamps, the light being of a pure white. The renewal of the carbons involves but a slight and infrequent expense, while the economy of the arc light per unit of current energy makes it very economical. This interesting novelty is manufactured by Messrs. Schefbauer & Co., of Paterson, N. J., and is being introduced by the E. P. Gleason Manufacturing Co., of this city, who have one on exhibition—the first that has been shown in public.

BLICKENSDERFER'S ELECTRIC RAILWAY SYSTEM.

While the ingenuity of many inventors is still being employed in the perfection of the details of overhead railway construction, not a few are at work on the solution of the best method of conduit construction for the reception of the conductors. Among the methods proposed are several in which avoidance of the slot has been a leading feature, and a recent plan with this object in view is that proposed by Mr. U. Blickensderfer, of Chicago.

The manner in which this is carried out is shown in the accompanying illustration, the general idea being to have



The Blickensderfer Electric Railway System.

a constant contact with the buried insulated conductor by making, as it were, a trolley of the car itself.

Contact with the moving car, whereby the motive current is conducted or transmitted to the car and its motor, is made by first flashing a temporary starting current through each helix or solenoid coil B, as the car advances, which raises the movable core D, till it comes in contact with the flat conductor-bar L placed longitudinally under the car. The initial, or starting current, therefore, is a temporary current. Its course or circuit is shown by a line of dashes in the engraving.

As the car wheel depresses each pin-head H, it brings the springs F and G together at *h*, which completes a circuit for the initial current, viz., from the main buried conductor A, through the solenoid coil B to the ground, for the return current.

The initial current flows only while the car wheel is treading each pin-head down, in passing. It is, therefore, but temporarily in action, its purpose being merely to raise each forward core before the car conductor-bar leaves the rearward core contact. But the instant the initial current flows, and raises the soft iron core D, it also magnetizes it; and then by virtue of its imparted magnetism, the core D in turn attracts the soft iron piece E, purposely placed on the end of the spring *c*, and draws the spring over till it touches at E the core D at its lower end. It thus completes a circuit for the motive current, viz., from the main buried conductor wire A, through the solenoid coil B, the spring *c*, core D, car conductor-bar L, and motor N, to ground. The course of the motive current is shown by the dotted lines.

As the motive current, after being put in circuit and action by the initial current, passes from the main A, by the wire *a*, first through the helix of the core D, and thence through the core, conductor-bar, car motor, etc., it takes the place of the temporary initial current in keeping the core raised, after the temporary current has flashed or performed its brief part, and then ceased. The motive current, therefore, by virtue of its course, continues to keep the core elevated to a contact with the car conductor-bar, as the car moves forward, and until it has passed by; and so on.

By the construction adopted the slot is avoided and no shock can be obtained by persons or animals passing, since the core bolts D are "dead," electrically, except when the car is over them.

THE WALKER ELECTRIC METER.

OUR readers will remember that in a recent issue[1] we described the electric meter designed by Mr. G. W. Walker, of the Walker Electric Co., this city. This apparatus, it will be remembered, is so constructed that the current strength is, as it were, continuously photographed, so that all disturbances or irregularities due to friction in the apparatus, were a mechanical marker employed, are done away with. Since our description above referred to has appeared, Mr. Walker has entirely remodeled his meter, though not altering the principle, but resulting in a simplification and re-arrangement of the parts, which considerably increase its efficiency.

The improved meter, as it appears at present, is shown in the accompanying engraving, Fig. 1, with the cover removed. As will be seen, it consists of an ammeter coil in the shape of a solenoid, in which an iron wire in the shape of a nearly complete circle is placed as a core; to the same shaft to which the circle or core of the armature is attached there is also fixed a light aluminum sector, provided with a fine vertical slot, and immediately behind

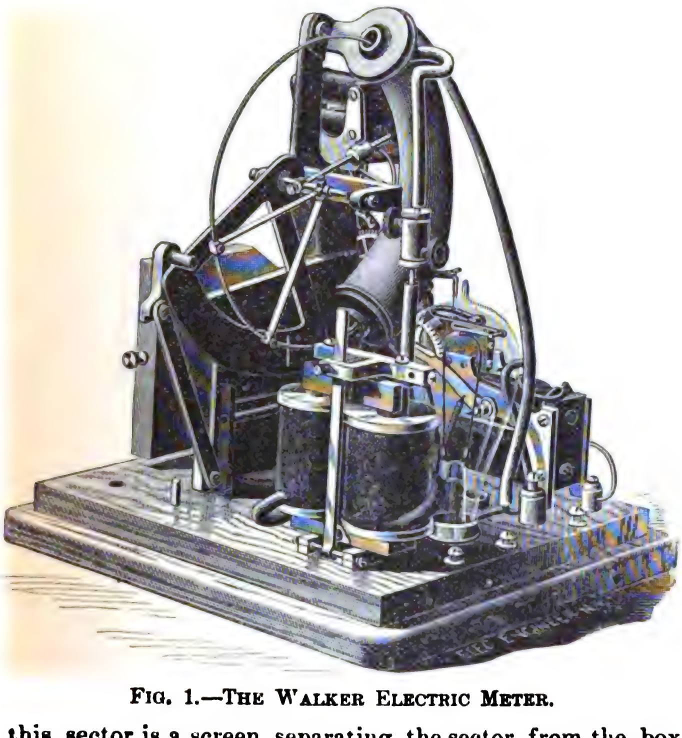


FIG. 1.—THE WALKER ELECTRIC METER.

this sector is a screen, separating the sector from the box which encloses a roll of sensitized photographic paper.

The interior of this box is shown enlarged in the engraving, Fig. 2. The screen before the box containing the sensitized paper has a horizontal slot, which permits the light from an incandescent lamp to fall upon the paper so as to form the line of light, J. Besides this there is a series of perforations in the screen, which permit the light to enter and form the dots, I, shown. The vertical slot in the sector is arranged to come immediately in front of a second horizontal slot in the screen, so that in whatever position it may be it will allow a ray of light to pass from the lamp and throw a single dot, H, upon the sensitized paper.

In this way it will be evident that, depending upon the strength of the current passing through the solenoid, the sector will take up a corresponding position which will be indicated by the impression made by the ray of light upon the moving paper. The varying position of the dot traces a curve which will be further away from the end of the box as the current is increased. The perforations forming the dots, I, shown, will cause a corresponding number of lines to be photographed on the paper, and these perforations are so spaced that the distance between two consecutive lines represents two amperes of current.

The slot which forms the horizontal line, J, is normally closed, but at intervals of one hour it is opened for a fraction of a minute so as to allow the line, J, to be photographed, and in this way the time record is obtained; the space between the successive lines, J, representing hours, are half an inch apart, and the curve formed by the moving dot of light, H, indicates continuously the ampere strength.

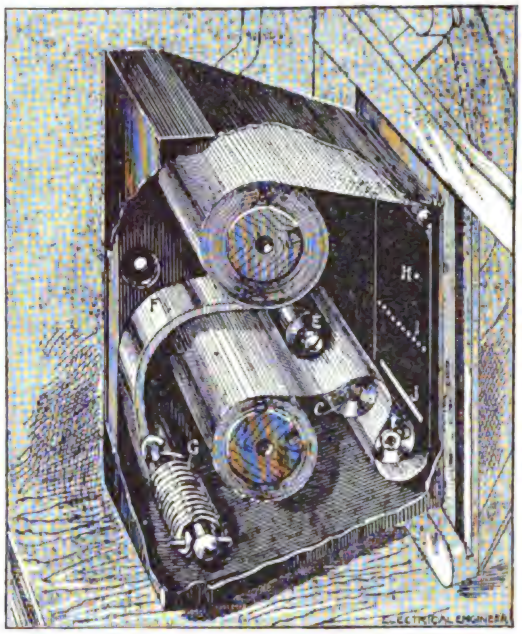

FIG. 2.—THE WALKER ELECTRIC METER.

It is evident, however, that some means must be provided for causing a continuous movement of the paper roll, and this is effected by means of a small clock movement which is wound automatically by the small electro-magnet shown in Fig. 1.

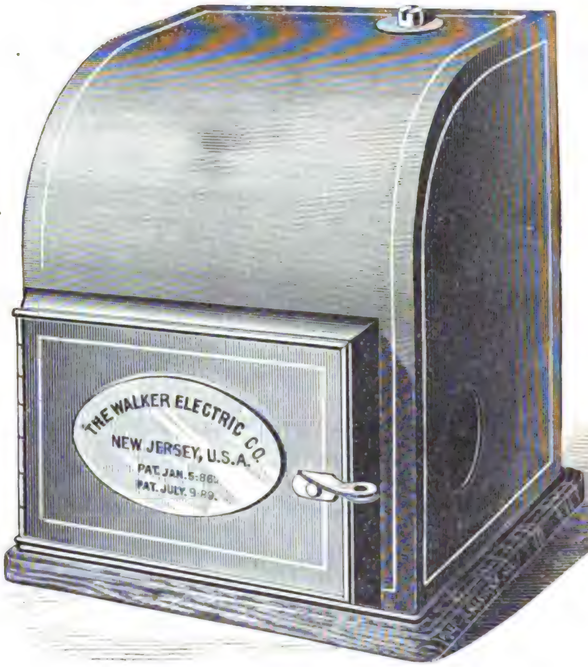

FIG. 3.—THE WALKER ELECTRIC METER.

The full roll of paper, it will be noticed, is mounted upon

1. THE ELECTRICAL ENGINEER, April 9, 1890.

a spindle, A, and after passing before the perforated screen passes to the receiving spindle, B. It is held taut by the roller, E, which is mounted on the arm, F, provided with a spring, G. By turning back the arm, F, the roll of paper can be easily slipped out and a new roll inserted. When no current is on, the meter is at rest, but the lighting of a single lamp immediately sends a current through the relay and photographing lamp shown in Fig. 1, which also starts a clock movement in operation that revolves the paper before the screen. A roll of paper sufficient to last one month may be placed in the box, after which time it is taken out and developed in the ordinary way.

The curve indicated on the chart can be readily measured up in the same way as a steam engine indicator diagram, so that practically no calculation is required to ascertain the number of ampere hours.

We have seen the Walker meter in operation, and the results obtained with it are very satisfactory. The engraving, Fig. 3, shows the meter covered completely and occupying a space of about one square foot.

CONVERTERS WITH CORES OF IRON FILINGS.

THE pernicious effects due to the generation of Foucault currents in the armatures of dynamo machines very soon led to their lamination, and the introduction of converters brought out still more prominently the necessity for the subdivision of the iron when subjected to changing magnetic conditions.

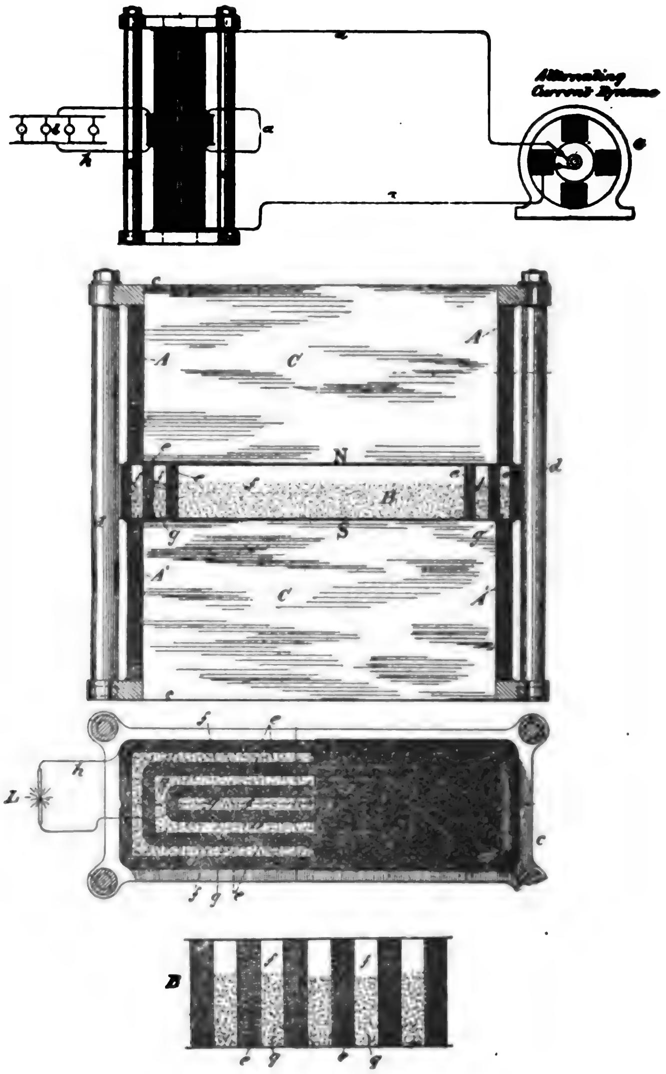
In carrying out still further the lamination or subdivision of the core, Mr. De Castro, of this city, has adopted a method, which is the subject of a recent patent, and which consists in the employment of iron filings, arranged in such way as to be loose or free to move, so that the particles may vibrate and be subjected to the action of magnetic lines of force derived from electro-magnets or from an exciting coil. The field of force in which the iron filings are thus placed is a varying field of rapidly-alternating polarity, which sets the mass of iron filings into rapid motion or vibration. The coils are arranged within inductive proximity to the vibrating mass of filings, and are influenced thereby for the induction of alternating currents.

The manner in which Mr. De Castro has carried out this idea is illustrated in the accompanying engravings, Fig. 1 showing the general arrangement and Figs. 2, 3 and 4 being views of the converter employed.

The coils, A A′, are the field or exciting coils, being included in a circuit, *a a*, and fed by an alternating-current dynamo. The coils are fitted with soft-iron cores, C C, laminated, as shown in Fig. 3, by being built up of plates of soft iron and clamped in to iron top and bottom plates, *c c*. They are arranged with their opposite polar ends, N S, facing one another and spaced sufficiently apart to make room between them for an armature or inductor, B, which consists of a coil arranged to be traversed by the lines of force induced by the coils, A A′. The outer ends or poles of the field-magnets are connected together to form a closed magnetic circuit through the medium of the posts, *d d*, which also form a mechanical connection between the top and bottom plates, *c c*, by which the whole structure is solidly united.

The inductor, B, as shown in Figs. 2, 3 and 4, is built up of two or more coils, *e e*, and intervening spaces, *f f*, the latter being closed at the top and bottom by plates of vulcanite, mica, or other non-magnetic substance. These spaces are partly filled with masses of iron filings, *g g*, which should be sufficient to about two-thirds fill the spaces or chambers.

In a state of rest the iron filings are held by gravity in the lower portions of the chambers, as shown in Fig. 4, the upper portions being empty. If now an alternating current be sent through the coils, A A′, thereby magnetizing their cores, the iron filings which are subjected to this rapidly-alternating field are set into active vibration. Their bodily movement is back and forth in one mass, or the mass may divide and its two portions may fly toward the opposite poles during one phase of the pulsation, and during the succeeding phase they may fall back toward the centre of the space, their vibration thus taking place toward and from the centre in two masses. In so doing each of the separate particles, being magnetized by induction, has the effect of a separate minute magnet moving through the coils, *e e*, and hence these coils, in addition to being excited by the mere projection of the lines of force from the magnets, A A′, through them, are further inductively affected by the bodily movement of the magnetic particles of iron



FIGS. 1, 2, 3 AND 4.—CONVERTERS WITH IRON FILINGS.

to the same effect as though so many separate small magnets were quickly moved into the coils.

The same idea has been applied by Mr. De Castro in the construction of the cores of dynamos, and experiments which he has made lead him to believe that by the employment of cores of subdivided iron or iron filings in lieu of solid cores, he can secure inductive effects of much greater intensity than heretofore and effect a considerable economy of electric energy and insure the conversion of a greater number of lines of force or energy than has heretofore been possible.

THE FRENCH CABLE.

The French Cable Co. is increasing its capital from 5½ to 11 million francs, and stock subscription books have been opened in Amsterdam, Brussels and Paris.

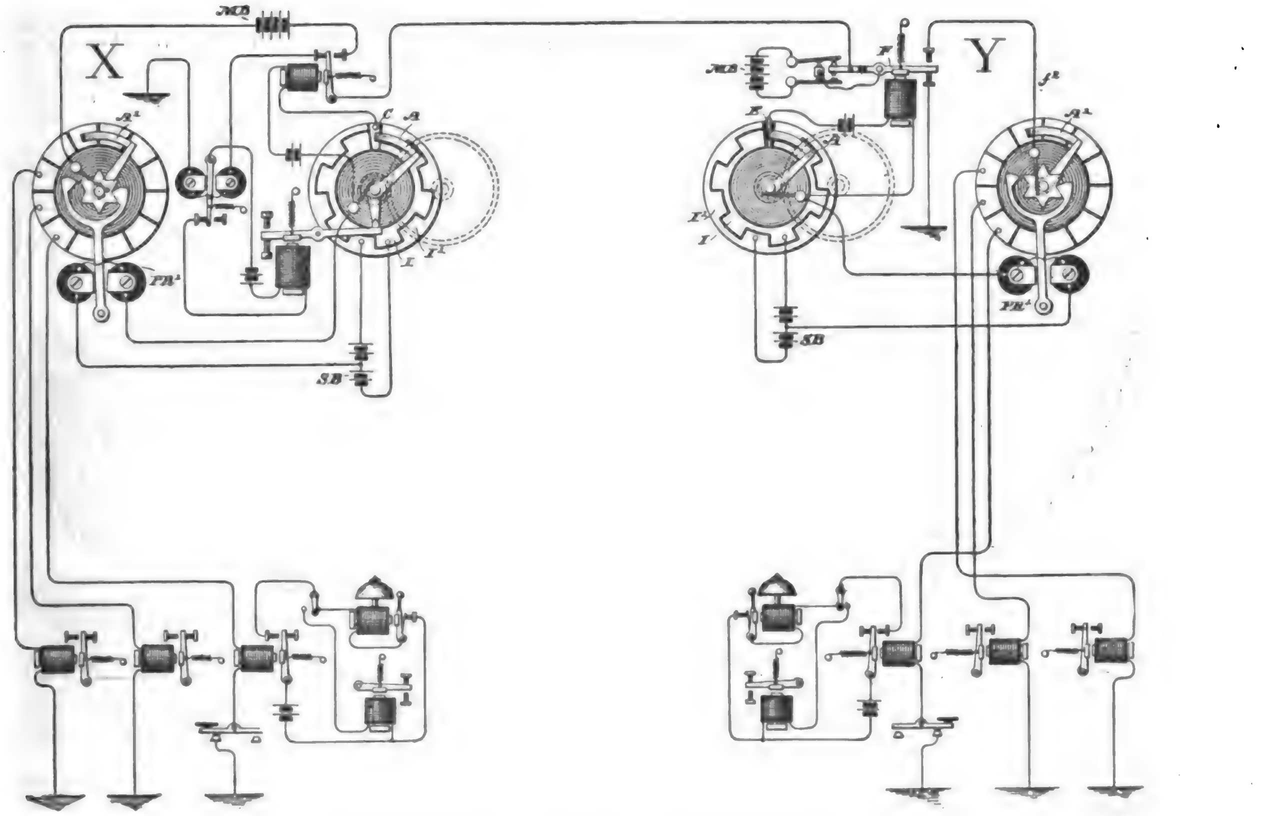
DELANY'S SYSTEM OF PRIVATE LINE TELEGRAPHY.

The necessity of having direct and rapid communication between correspondents in different cities some time since created the "private line," the use of which is constantly increasing among business firms. The heavy expense involved in this method where but one subscriber is at each end of the line has somewhat restricted the use of this method, and recognizing the need of some arrangement by which a line could be automatically distributed to a number of subscribers at stated intervals, Mr. Patrick B. Delany has recently patented a system adapted to both telegraph and telephone circuits. It appears to us that this idea, practically worked out, as it is, must supply a necessity now rapidly developing, and to meet which the Long Distance Telephone Company have already resorted to a system of hand transferring of lines simultaneously at both ends for such of their subscribers as do not require constant facilities.

Mr. Delany's system, which we illustrate in this issue, comprises an ingenious and effectual system of automatic switching controlled by a clock at each end of the line. It is so arranged that subscribers at distant points may be put in communication for five, ten, fifteen, twenty, thirty or more minutes in each hour. A New York subscriber having a branch house or correspondent in Boston, may, at a fixed yearly rental, subscribe for a line for five minutes in each hour throughout each day. Another pair of subscribers may arrange for ten minutes in each hour, or for five minutes in every half hour. Another pair may be accommodated with fifteen minutes each hour, and so on, until the whole time of the line is taken up. Thus a single line passed around periodically may be made to give ample facilities to a number of firms at a comparatively small cost to each. Very many concerns whose business does not warrant an exclusive wire will be attracted to a service which will give them just such facilities as they require, and relieve them from paying for more than they can use. This automatic system not only obviates the employment of switchmen, but insures decidedly more reliable and accurate distribution of the line, since the clocks are automatically regulated each hour, so that the transfer from one pair of subscribers to another must be simultaneous.

An important feature of the system is the elimination of the clocks from the main circuit, except during the one minute in each hour applied to their automatic correction. Thus there are no moving or scraping contacts in the circuit, and, furthermore, the clocks cannot be affected by any disarrangement of the wire. The automatic cutting in, correction, and cutting out of the clocks each hour is very ingenious and renders the rest of the operation quite simple.

At station X the trailer A carried by the clock mechanism is shown as resting on the correction-receiving segment C. From this segment a line runs through the neutral relay and local battery and back to the trailer. The neutral relay is therefore closed and the main line, which is connected to the armature, is grounded through its front post and the polarized relay. While in this position the main line is disconnected from the subscribers. Now, with the trailer at Y touching the small blade A, current from the positive pole of the main battery M. B. at Y energizes the polarized relay at X, drawing its armature against the tension of the biassing spring and closing the local circuit of the setting or correcting magnet of the clock at X.



Delany's System of Private Line Telegraphy.

On the end of the lever of this magnet is a wedge-shaped piece which, when the armature is drawn down to the magnet, enters a corresponding notch in the arm attached to the trailer shaft, and sets the trailer exactly in the centre of the correcting segment, or in a position corresponding to the thin segment over which the trailer at Y is passing, and from which the correcting impulse is being sent out. The sending correcting segment at Y is but about one-tenth the size of the segment for the reception of corrections at X. The latter represents one-sixtieth of

the circle, as the trailer is exactly one minute in passing over it.

The sending correction segment represents about five seconds; therefore, the clock at X may be half a minute slower or half a minute faster than the clock at Y and still be within the scope of correction from the small segment at Y.

Should the trailer at X reach the correcting segment before the trailer at Y reaches the small correction segment, no correction can be received at X from the operating battery at Y, which is normally on the line, for the reason that this battery attracts the armature of the polarized relay in the direction in which the spring is pulling it. Not until the trailer at Y reaches the small segment and closes the local circuit of the *pole changer*, putting the negative pole of the main battery M. B. to the line, will the polarized relay at X be affected. As soon as the trailer at Y passes off of the small segment the local circuit of the pole changer is broken, the positive pole of the main battery is restored to the line, and at the instant that the trailer at Y passes off of the insulation represented by the black line, the trailer at X passes off of the receiving segments for corrections, and the line is given to each of the first pair of subscribers exactly at the same instant.

The switching, or simultaneous transfer of the line, is accomplished in the following manner: The circuit table of the clocks comprises two parts or rings, with six projections on each, and brought together in alternately interlocking position, so that the twelve teeth or projections lie in the track of the trailing finger. The trailer corresponds to the minute hand of the clock. The projections represent five minutes each, because it takes the trailer five minutes to pass over one. The set, I, is connected to the negative pole of the split battery, S B, the other set, I^1, being connected to the positive pole of the same battery. This battery works the polarized switching instruments, P R^1. The main line is normally connected to the trailing finger, A^1, of these polarized switching instruments. There are twelve separate segments in the circuit table of these instruments. If there were twelve subscribers wanting five minutes facilities in each hour, each would be connected to one of these segments. The one minute appropriated to the correction may be taken from the last or first subscriber, and allowance made in his rental for the same.

In the diagram the trailers of the clocks are shown at unison, and the trailers of the switching instruments are on the segments of the last subscriber. When the clock trailers pass to the first projection of plate I^1, the batteries of the polarized switching instruments, P R^1, will be reversed, and the trailers connected to the main line are moved to the next pair of subscribers by the movement of the pawled armature levers. When, at the end of five minutes, the clock trailers reach a tooth on plate I, the batteries of the polarized switching instrument are again reversed, and the line is transferred to the next pair of subscribers, and so the transfer goes on regularly so long as the clock is wound up every eight days. It will be seen that the transfer of the line is made simultaneously and with a snap, and that the main line contact is quiet until the time expires. Any portion of an hour may be given to any pair of subscribers by simply connecting the subscriber's branch line to the number of segments required. The branch lines to the subscribers are normally switched to a vibrating bell, so that when the circuit comes on, the operator's attention may be attracted and no time lost.

NOISELESS GEARS FOR ELECTRIC CARS.

THE method of transmitting the power of the motor to the axles of electric cars has absorbed probably as much attention as any other detail of electric car construction. In the method now generally in use, owing to the high speed of the armature, it is customary to use a small pinion, and at least one counter-shaft between the armature and the large gear on the axle, in order to get the desired reduction in the number of revolutions of the car wheel. These gears and pinions are subjected to very heavy duty and, in addition, are exposed to dust and dirt, which, in comparatively short time, necessitates their renewal, involving considerable expense. In order to avoid this, and at the same time to provide a noiseless gear, Messrs. Chadbourne, Hazelton & Co., general agents for the Wenstrom Consolidated Dynamo and Motor Co., have recently brought out an interchangeable elastic gear which possesses a number of novel features.

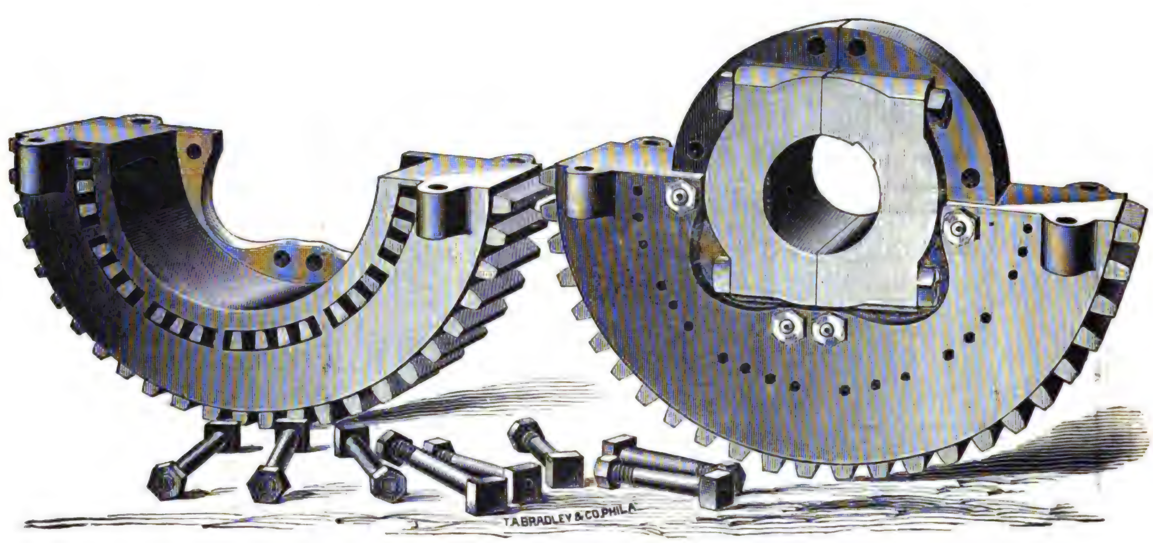


FIG. 3.—SPLIT AXLE GEAR, SHOWING HUB AND SECTION OF COGGED RIM REMOVED.

The manufacturers of this gear have started out on the principle that contrary to the present practice, where one of the gear wheels is made of softer material than the other, the softer cog should be put in the wheel having the greatest number of teeth. The manner in which this has been carried out is shown in the accompanying engravings, Figs. 1 and 2, which illustrate the new intermediate gear as a whole, and as taken apart to show its construction.

As will be seen, the gear is made up of three separate parts: The blank or hub which is keyed fast to the axle; the removable rim which holds the cogs, and which is bolted to the hub; and lastly the wooden teeth, which are inserted in the rim. At first thought it may seem that the wooden teeth would hardly stand the strain and wear and

FIG. 1.—INTERMEDIATE GEAR AND PINION.

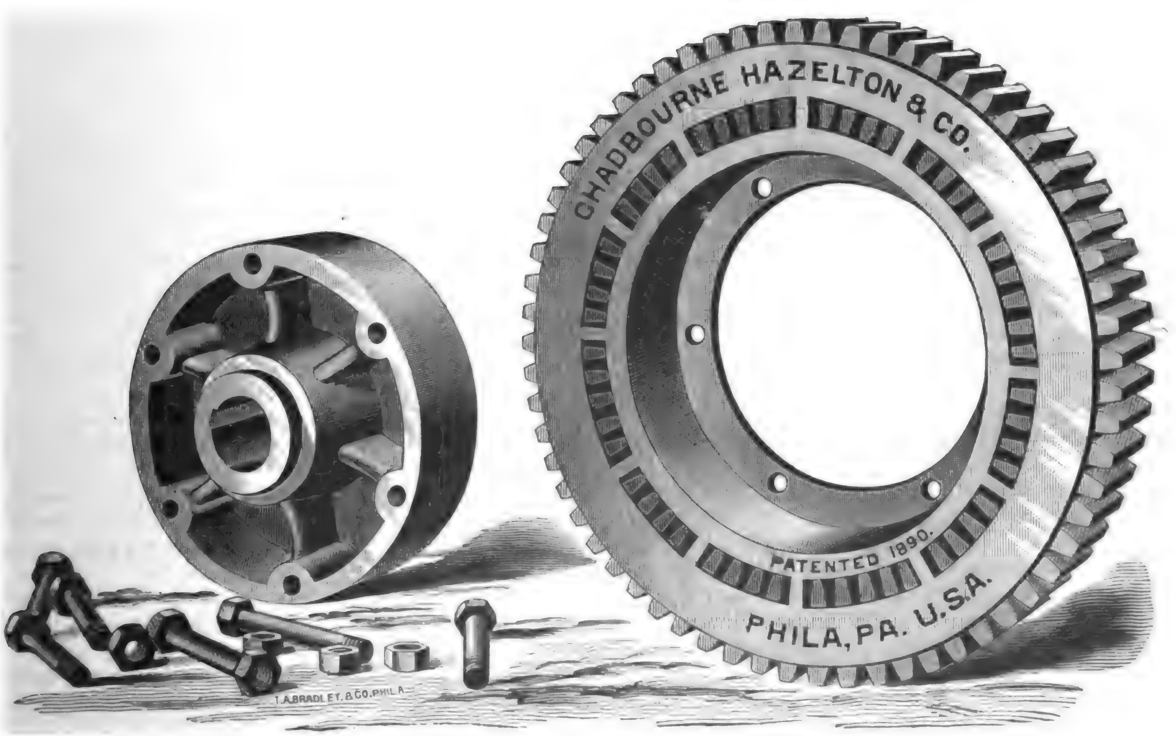

FIG. 2.—INTERMEDIATE GEAR, SHOWING RIM REMOVED.

tear which is brought upon them in street car service, but in New England, where the largest mills are driven by turbine wheels, and where thousands of horse power are used in a single mill, this entire power is transmitted through bevel gearing, the larger gear always having wooden cogs, for the reason that nothing else has yet been found that would stand the work. These cogs last several years, and then are renewed at a slight expense, being simply driven in the iron frame of the wheel, and they have the advantage of being elastic and noiseless.

The teeth which are used in these gear are of selected wood, and are driven in with white lead, and wedged at the base in the usual way; they are then put into the gear cutter and cut in the ordinary manner. The rim is made of a specially fine grade of cast iron and slips over the blank, being held in place by six bolts. Between the rim and the hub is laid a sheet of oil paper, which prevents any corrosion, and also stops any vibration or "bell tone" from the gear.

The blank is keyed firmly to the intermediate shaft and need never be removed. After the wooden teeth have become entirely worn out, all that is necessary is to remove the six bolts and slide off the rim; an extra rim with the teeth in it can then be put on, the entire change not occupying over ten or fifteen minutes. Any ordinary carpenter or wheelwright can then re-cog the old rim and cut the teeth in a half day's time, so that the expense of replacing the cogs is merely nominal.

The armature pinion is made of forged steel with the teeth case hardened after being cut.

The split gear intended for the axle is shown in Fig. 3. In order to avoid breakage and noise the same construction is employed as in the intermediate gear. The split gear is composed of two parts, the blank or hub which is split and put on to the axle, and the rim which is also split and put on so as to break joints with the hub.

These gears have been adopted on the electric railways at Atlantic City, Wilmington, Richmond, and a number of other places, where they have given excellent satisfaction.

THE DEVELOPMENT OF THE PHONOGRAPH.

BY T. C. MARTIN.

THE writer has had in his hands during the past week a volume of unusual interest and importance. It is the report by Edison phonograph of the meeting of the Association of Phonograph Companies held in Chicago last May. The convention lasted two days. In place of the stenographer, with his paraphernalia of note books and pencils, appeared the little machine that so many people are still apt to regard as a toy; and all that was said was indelibly written with the tongue. The proceedings of one day were "taken down" by the graphophone, and of the other day by the phonograph. The record made by the phonograph on May 29 comprises 40,000 words upon 61 cylinders. It has now been transcribed by typewriter, and the first copy, handsomely bound, has been sent to Mr. Thos. A. Edison for the library of his laboratory at Llewellyn Park.

The method of reporting or recording is simple. Two machines stand side by side at the place usually occupied by the stenographer. The speakers address the meeting from any point they choose, or if, like Henry Clay or Henry Ward Beecher, they walk about while they declaim, no objection is offered. As they speak, the reporter, seated at machine No. 1, repeats every word softly yet distinctly, prefacing each speech by the name of the man who makes it. The cylinder being rated to carry 1,000 words, it becomes necessary when that limit is approached to quit machine No. 1 and to begin work on machine No. 2. This is done very easily. By the time No. 2 cylinder is charged with words, No. 1 is ready once more, and again a change of position is made. The results are eminently satisfactory. The slight movement is attended by no fatigue or inconvenience, and it is not at all difficult, even with a fast talker, to carry over and continue the record. A little knack and study soon enables one to chase close upon the heels of the orator, and even to anticipate the conclusion of many of his sentences. Any good stenographer is familiar with that part of reporting work, and naturally such a man is quicker at it than one whose mind is not so trained, to become expert in the new art. One great point that presents itself to notice is that the record is ready for immediate transcription. Very often no one can read the stenographer's lines and curves but himself, and sometimes the best stenographer is baffled by notes only a few hours cold. But there is no difficulty here. Of course, as in ordinary stenographic work, the reporting staff can work in relays, and one machine take up the thread of discourse where the other drops it.

Such a performance as this to which the bulky volume of 40,000 typewritten words bears evidence is not to be gainsaid. It has to be dealt with on its merits, and all the harsh criticism in the world can but leave the fact as much a fact as ever. Since the phonograph has attained this degree of practical perfection and usefulness, it becomes more than ever an object of importance in the eyes of electricians and electrical engineers.

At the present time there are in the neighborhood of 8000 phonographs and Tainter graphophones in use in this country, the phonograph largely preponderating, it is said. Both instruments are made, rented and operated under the controlling patents owned by the North American Phonograph Company, which, with a capital of $6,600,000, has its headquarters in New York city. This company has as licensees throughout the country the following sub-companies, very much as the telephone companies are the representatives of the parent company in Boston :—

The Michigan Phonograph Company; the New England Phonograph Company; the Wisconsin Phonograph Company; the Kansas Phonograph Company; the Western Pennsylvania Phonograph Company; the Pacific Phonograph Company; the Ohio Phonograph Company; the Columbia Phonograph Company; the Florida Phonograph Company; the New York Phonograph Company; the Nebraska Phonograph Company; the Texas Phonograph Company; the Missouri Phonograph Company; the Minnesota Phonograph Company; the New Jersey Phonograph Company; the Iowa Phonograph Company; the Spokane Phonograph Company; the West Coast Phonograph Company; the Alabama Phonograph Company; the Colorado and Utah Phonograph Company; the South Dakota Phonograph Company; the Montana Phonograph Company; the Georgia Phonograph Company; the Kentucky Phonograph Company; the Eastern Pennsylvania Phonograph Company; the Tennessee Phonograph Company; the Wyoming Phonograph Company; the Central Nebraska Phonograph Company; the Old Dominion Phonograph Company; the Chicago Central Phonograph Company; the State Phonograph Company of Illinois. The names of these corporations fairly mark out their territory. The Kansas Company operates also in New Mexico; the Columbia (D. C.) Company in the States of Maryland and Delaware; the Missouri Company in Arkansas and the Indian Territory; the Old Dominion Company in Virginia, North Carolina and South Carolina. These 31 companies, many of which are of recent formation, represent a capital that probably approximates $20,000,000. All of them are at work, and not a few are experiencing a very rapid growth of business.

It would, in fact, be rather difficult to determine the bounds of phonographic development, so varied and numerous are the avenues of employment that open up to it. Verbatim reporting is one of these, and but small. The machine is finding its way with quiet swiftness into all manner of business offices. One firm in Chicago uses 8; another house in Richmond is not satisfied with less than 16.

A large number are rendering excellent service in editorial and publishing offices. The Electrical Engineer has two, and will soon have more. Out in Milwaukee, two printing offices have made a specialty of setting up from phonographs, the compositors dispensing with time-honored "takes" of copy. Cleaner proofs are the result. Under such a régime Horace Greeleys cease to be a terror to the inoffensive "comp." A large number of lawyers, patent solicitors, stenographers, clergymen, authors, actors, musicians, linguists and other professional men are using the machines. An interesting and novel feature is the use of the machine for obtaining daily reports from foremen in large factories. Such men can generally talk vigorously and well, but a pen they shun and abhor. It has been discovered, however, that they will "pour out heart affluence in discursive talk" upon a waxen cylinder in a most admirable and effective manner; and this new method of factory reports is naturally coming into vogue with gratification to all parties concerned. Out of the whole 8,000 machines, it is estimated that 75 per cent. are in business service. New York has already 600 machines running.

The motive power to run the machines is a subject that is still actively discussed. This question can hardly be settled yet. The phonograph is driven by the ingenious little motor invented by Mr. Edison for the purpose; but that motor is energized in various ways. Sometimes the current is derived from an Edison-Lalande battery, one great advantage of which is its constancy. Sometimes the current is taken, through a resistance, from the incandescent lighting circuits. There is a very general preference for storage batteries, and nearly all the makes have been tried. With the graphophone have been coupled Lugo and other motors; and the small size Perret has been found very successful. In view of the fact that the 8,000 machines bid fair to become 800,000 in the next ten years, it will be seen that this question of motor and current for them is not one of the least interesting now before the electrical community. The customer of the sub-company pays $40 for his machine per year, or the small sum of 75 cents per week. The supplies are extras, of course, and there is a vast field for work and ingenuity in many of their details. By and by it may become a general practice for the companies to furnish the supplies to their patrons on a certain "flat rate" annual basis.

Amusement phonographs are still new, for, although countless exhibitions have been given, we have but barely entered on the nickel-in-the-slot period, when music and oratory, song and speech will be on tap. Nickel-in-the-slot phonographs have proved immensely popular whereever introduced, and there is not the slightest reason to believe that the favor they are in will be simply a short-lived craze. Every week brings forth its new singer, its new song, its new march or air; and the public has an ear that likes to be tickled. The phonograph as a Joe Miller jest book, telling the latest as well as the oldest good story, is an amusing companion. Incised with a yarn and a laugh from Eli Perkins, it is in more senses than one a "howling success."

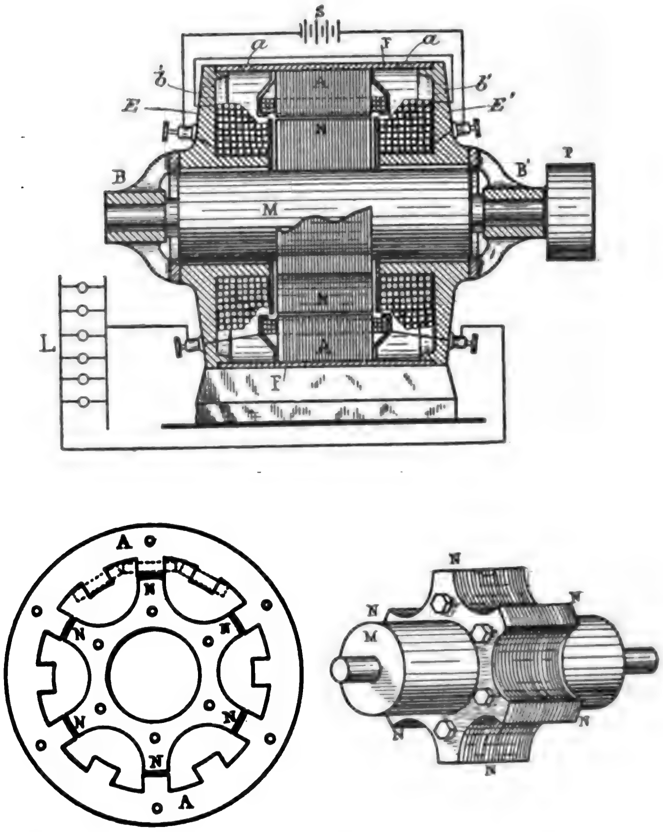
The past week, which has seen the issuance of this phonographic report has by strange coincidence seen, also, the issuance of an order from Washington for the treatment of phonograms as other ordinary mail matter. This is a step forward, and will lead to other improvements and developments, especially, it may be assumed, in the standardizing and unifying of apparatus, so that the same machine and the same record cylinder serve the same purpose everywhere.

The Elgin, Ill., Electric Railway, which has recently been equipped with the Sprague system and was started up on the 4th of July, ran from the start without the slightest hitch, although no previous tests had been made of any of the power or electrical plant. The road was started with 2 cars, which they have already increased, and added another 50,000 watt generator. The cars were run free at the start till 12 o'clock, after which till 10 p. m. 4667 nickels were taken in fares.

PROF. THOMSON'S NEW ALTERNATING MACHINE.

With the high speeds now generally employed in alternating current machines the moving coils are more or less liable to derangement, so that they are subject to both mechanical as well as electrical strain. In order to overcome this difficulty and to obtain a compact as well as efficient machine, Prof. Elihu Thomson has recently constructed an alternator in which all the coils are stationary, and so that no moving contacts whatever are necessary to conduct the current from machine to line. The machine is shown in section in the accompanying illustration, Fig. 1, and consists of a stationary armature A, Fig. 2, within which revolves the field magnet, shown in Fig. 3.

The armature A is built up of a number of ring-shaped plates or sections of rings bolted together to form practically a compound laminated ring. It corresponds in a



Figs. 1, 2 and 3.—Thomson's New Alternating Machine.

measure to a fixed laminated armature, and is supported in the interior of the outside casing.

The end plates E E' are joined at their outer portions by the iron frame-work or casing F, consisting of a cylinder surrounding the machine. It is designed to connect the outer edges of the end plates E E' magnetically with the stationary laminated ring A, surrounding the core M so as to embrace the centrally projecting portions of the core M. To the inner side of the structure A, and upon projections extending radially inward, are applied the coils, the ring and coils thus resembling a multipolar ring or cylindrical-shaped magnet whose poles are on the inside.

The field magnet coils are supported fixedly in the casing and energize the multipolar field magnet M, all the poles of which are of like name, as shown at N, N, etc. The core M is fixed to the shaft of the machine and has the laminated pole pieces keyed to it.

The ring structure A A has interior projections of double the number of the projecting poles N N N, carried by the ring core-piece. On these projections are firmly secured the coils in which currents are to be induced, and which are connected to the line wires. The field magnets, of

course, require to be energized by a continuous current which can be furnished by a separate exciting machine.

The action of the machine is as follows: The moving field-poles N N N, etc., carried around on the revolution of the core-piece M, pass in front of the coils in which the currents are to be induced. The lines of magnetic force projecting from these pole-pieces cut across the wire on the coils transversely. The direction of the winding and the connection is such as to make the effects cumulative in the coils—that is, so that if a polar projection N passes, as in Fig. 2, over the centre of one coil to that of the next its lines are caused to cut the wire lying between those centres, half of which would belong to that coil, the centre of which is being left by the traveling pole, and half to the coil toward the centre of which the traveling pole is moving.

These actions of induction repeatedly following one another will be accomplished without a reversal of magnetism in the core-piece or even in the laminated ring structure supporting the coils in which the currents are induced; but, on the contrary, the lines of force will simply be carried rapidly past wire whose virtual direction of winding is opposite alternately, and this will generate impulses without the necessity of magnetic changes of polarity taking place in any of the core-pieces. Prof. Thomson is thus enabled to save a large portion of the loss due to magnetic changes or "hysteresis," in the iron of the machine, while still utilizing the iron to the best advantage in the construction of the magnetic masses subject to the magnetizing actions of the field-energizing coils. There is also secured a strong magnetic field by the expenditure of a minimum of energy in sustaining the same, besides which none of the wire of the machine need revolve, thus dispensing with rubbing-surfaces or sliding contacts when the machine is used for the generation of alternating currents.

ELECTRIC POWER AT GLOVERSVILLE, N. Y.

THE work now being done by electric motors at Gloversville, N. Y., the largest glove manufacturing town in the United States, is of more than ordinary interest, and presents one or two novel features. The Gloversville Electric Company started their plant on December 1, 1889, and began to supply electric power just a month later. They are now operating 26 motors ranging from ½ to 2 h. p., and these 26 machines represent so many different glove factories. The ½ h. p. motors run eight sewing machines each; the 1 h. p. from 12 to 14 machines; and the 2 h. p. from 18 to 22 machines. The prices for current are $90 per year for 1 h. p. and $35 for the use of the motor; $50 for ½ h. p., and $25 for use of motor; $175 for 2 h. p. and $50 for use of motor. The motors are owned and supplied by the company. The users have become familiar with their care, and they give very little trouble to the company in the care of them; but they are of course kept under surveillance and a weekly inspection.

The service is furnished from 7 A. M. to 6 P. M, each day, with an intermission at noon, and proves very satisfactory to its patrons. The power is supplied by Thomson-Houston arc machines generating a current of 6.8 amperes. These machines are used at the end of the day for lighting the town with arc lamps. The motors used are the constant current made by the Excelsior Electric Co., of this city, and have been found eminently suitable for their work. The Gloversville company now have applications for power as high as 40 h. p., and they are considering the advisability of putting in large generators to deliver a 500 volt current to furnish power for that special work. The company are obtaining their prime power from compound condensing engines, that answer admirably and are preferred to the ordinary non-condensing high speed type.

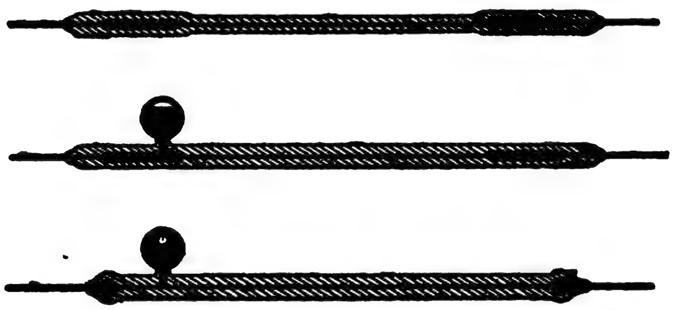
The company have begun to furnish motors as small as ⅛ h. p., running the service right into the houses of the operators, so that as the work is paid for by the piece, they can take it home and do it outside the factories. This is a little point, but it has its significance.

The factories really make money by the motors they put in, as they charge the "help" that use the machines 50 cents per week for the use of the motor, the work being done by the piece, as stated above. At first no little objection was made to this, but now the operators are glad to pay the charge, for the reason that they are enabled to do very much more work with the machine run by the motor than in the old way. There is thus a saving and a higher profit in the work for everybody concerned.

FIELD'S MERCURY THERMAL CUT-OUT.

The protection of telegraph and telephone apparatus from abnormal currents has led to the construction of a large number of cut-outs, both electro-magnet and thermal in their nature. In order to avoid the introduction of an electro-magnetic device which might introduce retardation, and on the other hand to overcome the objection to lack of uniformity and fragility in fine fuse wires, Mr. Stephen D. Field has recently invented an ingenious cut-out in which mercury is employed as the fusible, or rather volatile, material. Another object aimed at is to obtain such a construction that upon the cessation of the abnormal current the circuit to the instrument is automatically restored without the replacement of any material in the cut-out.

The simplest form of Mr. Field's cut-out is illustrated in the accompanying engraving, Fig. 1. It consists merely



FIGS. 1, 2 AND 3.—FIELD'S MERCURY CUT-OUT.

of a glass tube with a fine bore which is filled with mercury and has two conducting wires sealed in at the ends. The passage of an abnormal current heats the mercury, vaporizes it and the pressure generated bursts the tube, thus rupturing the circuit.

In order to provide for the automatic closing of the circuit above referred to, the construction shown in Fig. 2 is employed. Here a chamber is placed at one end of the tube, which is part filled with the mercury. The air, which occupies a portion of the chamber, being an elastic medium, allows the expansion due to the vaporization of the mercury in the capillary portion to take place without rupturing the structure, as the air becomes compressed and the separation of the column of mercury in the capillarly tube can take place, thus opening the circuit in a reliable manner without destroying the apparatus,

Another form of cut-out, shown in Fig. 3, is similar to that shown in Fig. 2, except that instead of leaving a open air-space in the chamber, a rubber ball filled with air is placed in it and the chamber completely filled with mercury This prevents the escape of the air from the chamber into the capillary tube in transporting or handling the appaatus, while affording a sufficiently elastic medium to preserve the apparatus from destruction by the vapor-pressure gnerated in its operation.

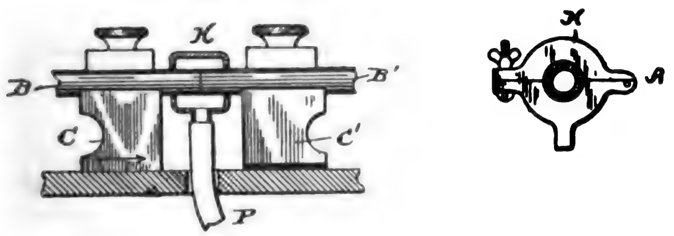
Among the practical advantages claimed by Mr. Field for this form of cut-out, are first, that, if using only pure distilled mercury, it is possible to have absolute uniformity in the conductivity of a given size of cut-out. Again, the

construction of capillary tubes of glass has reached such a stage of perfection that it is entirely practicable to have a given diameter uniformly reproduced, and, furthermore, the diameter may be very much smaller than it is possible to draw any of the known fusible wire metals or alloys. Again, mercury has a very high coefficient of resistance. It therefore becomes possible and entirely practicable to construct thermal cut-outs of this character so as to permit an exceedingly small fraction of an ampere to volatilize the mercury at the point of least diameter, and the action will take place invariably at the same critical temperature. We have seen the cut-out in operation and it seems to fulfill all the claims made for it by Mr. Field.

THOMSON'S METHOD OF ELECTRIC CASE-HARDENING.

Prof. Elihu Thomson has already devised a variety of ways of working metals by means of the heat generated in them by the passage of the electric current, and has recently added to these another interesting method de signed to case-harden the metals, such as iron or steel. The process consists essentially in heating the object electrically, and then applying to the metal so heated a surrounding envelope (either gaseous, fluid or solid), for the purpose of changing or preventing change in the quality of the material, according to the special end to be attained.

The method is applicable not only to those cases where it is desirable to prevent oxidation or change of character



Figs. 1 and 2.—Thomson's Electric Case-Hardening Process.

in the surface of the metal object which is heated in the welding, forging, or shaping operation, but is also applicable to producing an addition to, or modification in, the character of the surfaces of the metal object, either independently of, or simultaneously with, the forging, shaping, or other working operation performed upon the metal. Thus, for instance, it can be applied to the local hardening of parts of steel bars and the local case-hardening of iron or mild steel bars when heated by the passage of the current for the purpose of welding, forging, shaping, etc.

To prevent oxidation Prof. Thomson surrounds the iron and steel bars with a hydrocarbon gas or other gas containing no oxygen, such as hydrogen or nitrogen. To chill and harden steel the heated bars are suddenly surrounded with cooling-fluid, such as water or oil. To case-harden the bar it is surrounded with a layer of case-hardening flux—such as cyanide of potassium, yellow prussiate of potash, shavings of horn, animal charcoal, leather cuttings, and carbonate of potash, or the like—and the pieces kept hot by the current until the required case-hardening is effected as a result of the addition of carbon to the surface layer of the material.

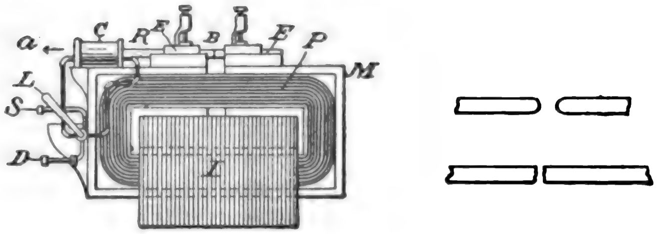
The accompanying illustration, Fig. 1, shows the apparatus designed to accomplish this. As shown, the bar to be treated is surrounded by a casing, K. This casing is supplied, through a pipe, P, with ordinary coal-gas or gasoline-vapor during the heating of the metal, so as to preserve the same from oxidation during the welding or like operation performed upon the object heated.

The casing is constructed of sheet-iron, and made in two parts, hinged at A, as shown in Fig. 2. Evidently it must not make electrical contact with the object treated, but must be guarded therefrom by mica, asbestos, or other insulating and refractory material applied at the points where the object enters the casing.

Oxidizable metals are by this means thoroughly protected at their surface, and, in fact, with gases rich in carbon, will receive when highly heated a veritable protective layer of deposited carbon, which gradually carbonizes the surface of an iron bar while heated and steelifies or case-hardens it.

LEMP'S METHOD OF ELECTRIC SWAGING.

Among the recent developments of the electric welding process of Prof. Elihu Thomson, is a method of swaging metals devised by Mr. Hermann Lemp, of the Thomson Electric Welding Co. The apparatus employed for this purpose is shown in the accompanying engraving, Fig. 1,

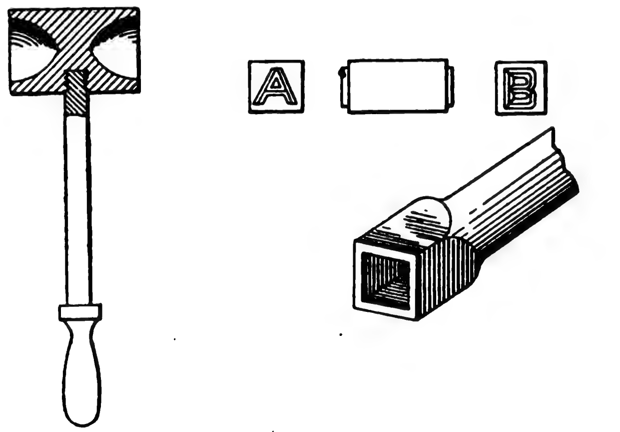


Figs. 1 and 2.—Lemp's Method of Electric Swaging.

and will be seen to consist of a welding transformer, one clamp of which is made movable.

The latter clamp is actuated by means of a piston-rod, B, secured to a piston working in a cylinder, C. Steam or air pressure is applied at opposite ends of the cylinder through pipes controlled by a four-way valve, the handle of which is indicated at L. In one position of the handle communication is opened between the inlet, S, and one end of the cylinder and between the outlet, D, and the opposite end, so as to move the clamp toward the opposite one. In the reverse position of the handle the condition is reversed, the inlet, S, being connected with the proper end of the cylinder to produce a reverse movement and the outlet, D, with the opposite end.

The operation of the apparatus is as follows, B being the bar or piece of metal which is to be manipulated. After



Figs. 3, 4, 5 and 6.—Lemp's Method of Electric Swaging.

clamping, the current is turned on until the portion of the metal between the clamps is heated and softened, when, through the application of pressure the cylinder bar is divided into two pieces. It is advisable to stop the current just before the separation, thus leaving two pieces such as shown in Fig. 2. By separating the bar quickly the ends will be left as in Fig. 3. The two pieces with their ends in plastic condition having been thus formed, the double forming device or holder—such as shown in Fig. 4—is placed between the ends of the heated bars, and the lever, L, is turned into position so as to cause the

clamps to approach one another, thus pressing each hot end and the die or former together, so that the metal will assume the shape of the forming or swaging device. In this instance a conoidal form is given to the end of the bar. The shaping device interposed between the two ends of the heated metal might be a die, as shown in Fig. 5, in which case each hot-metal piece would be made into a stamp.

The production of a tool such as indicated in Fig. 6 by the process described is obvious, it only being necessary in such case to use a die or former which shall shape the metal into the form indicated after the heating of the blank in the clamps or holders, as before described.

It is obvious that by this method of procedure metal may be shaped with great expedition, as no time is lost in the removal of the metal from the clamps or holders of the electric-heating apparatus.

AN ELECTRICAL EFFECT[1].

It may be of value to remind teachers of an effect not generally known, which is produced by varying the ordinary mode of performing the experiment of putting pieces of zinc and silver in the mouth and touching them, to obtain the acid taste which accompanies the completion of the electric circuit.

If the piece of zinc be placed under the tongue, and a florin vertically between the upper lip and the top row of teeth, and the two metals be brought in contact, a faint flash is seen in both eyes when the eyes are open.

If the eyes are shut the sensation of light is not felt, so that the effect is probably due to a muscular twitching.

It is necessary to use a large silver coin, and not a shilling, and to push it well home behind the upper lip.

The experiment so made seems to be a handy and simple illustration of the meaning of subjective phenomena.

A NOVEL ELECTRIC RAILWAY POLE-TOP.

A glance at the electric railways in this country will show a number of poles of different designs now in use. How serviceable the different forms are will depend on the rigidity of the pole and partly on the design of the pole-top. That the pole should stand a great side-pull without

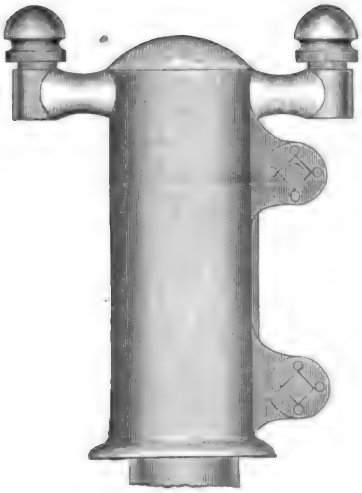


Fig. 1.—The Verstraete Pole Top.

much bending was early seen, but only lately has due attention been given to the features needed in pole-tops. These should be strongly made, so shaped as to shed the water, and should insulate both trolley and guard wires from each other and from the pole. Then there should be ready means of taking up the slack in both of the suspension wires, and two insulators for carrying the feeders. These features seem to be embodied in the new pole-top designed by Mr. Edmund Verstraete, the electrician in charge of the construction of the Union Depot Railway Company's plant in St. Louis.

As shown in the accompanying engravings, it is an iron cap which may be used with either iron or wooden poles. The wooden poles do not need to fit it tightly, as the pull of the guy-wires will keep it pressed against one side of the pole. The pole-top is merely slipped over the end of the wood poles, the top adjusting itself. With iron poles a wooden plug and a wood bushing is used, as shown in the section Fig. 2. These bushings are thoroughly soaked with Simplex paint; and as the iron flange keeps the adjacent

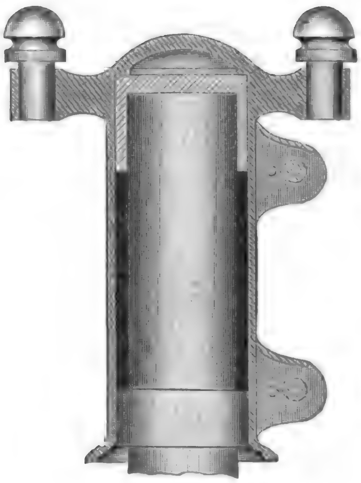

Fig. 2.—The Verstraete Pole Top.

part of the pole dry, the top is always insulated from it. The lower end of the pole-top is flared out so as to shed the water, and keep the upper part of the pole dry; this insures the insulation of the trolley wire from the ground.

The suspension wires are wound on a drum, whose enlarged ends have six holes; a pin through one of these holes keeps the drum from unwinding. These pins cannot drop out, yet allow the slack of the wires to be readily taken up. The drums for the guard wires is 9 inches above that for the trolley wire, and is made of insulating material. The insulators for carrying the mains or feeders are above the guard wire; hence if both the trolley and the guard lines are put up before the mains are, the latter need not be slipped through between the suspension wires, but are readily thrown over the top and fastened to the insulators. The pole-top is well built, simple and inexpensive, and seems to be eminently practical. It is made by the Great Western Electric Supply Co., Chicago.

A SERIES STORAGE BATTERY.

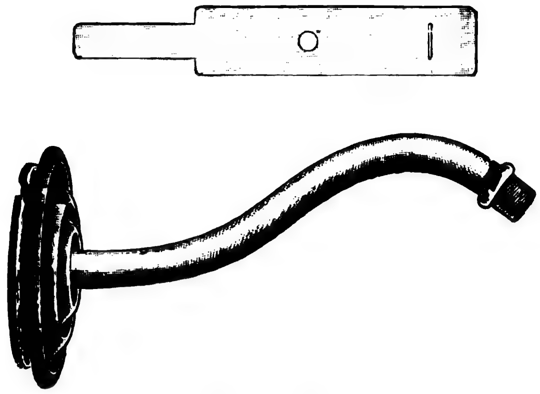
There has recently been brought out in London a storage battery designed especially for lighting on a small scale, such as carriage lighting, which embodies some novel features. The battery consists of a wooden cell, divided into separate partitions by the battery plates. The opposite sides of a plate are therefore of an opposite character; one side being, as it were, positive, and the other negative. The plates in a cell are therefore in series, and no electrical connections whatever are required, except at the two end plates. A wooden frame between the plates prevents buckling. A box 14 in. long, 4¼ in. wide, and 6 in. deep, will contain a battery of 24 plates, that is, 24 cells; and this, we are informed, will yield 18 amperes at 48 volts. The plates are cast with square recesses, for holding the peroxide, and probably would discharge at a rate comparing fairly with other accumulators.

The Sprague Electric Railway and Motor Company, through their Chicago office, have just closed a contract at Fort Scott, Kan., to build five miles of road, to be equipped with six cars and one 110 horse-power generator.

1. Edward B. Cook, in *Nature*.

DETAILS OF THE INTERIOR CONDUIT SYSTEM.

Last week we were enabled to show diagrams illustrative of the manner in which, by resorting to the "crib" system, the Interior Conduit and Insulation Co. introduced their tubes into and throughout buildings. No reference was made, however, to the details of construction, which are equally worthy of note. As the tube comes in sections, it is obviously necessary to bring sections together in order to afford the continuous channel for the wire. In Fig. 1 is



Figs. 5 and 6.

shown the threading tool with which is furnished a complete set of dies for all sizes of the tube; Fig. 2 is a section of conduit showing threaded end as used with screw coupling, and Fig. 3 is a sectional view of the screw joint with the coupling in position. The couplings are sometimes of metal. When the lengths have been coupled together, and the run is complete, powdered soapstone is blown through the tube to smooth the way for the wire, which is then fished through very easily with the help of a

Details of the Interior Conduit System.

crinoline steel fishing wire, at the front end of which is a little ball or leader on a universal joint, giving it free play to turn in any direction. As many as four elbows can be gone around with a flexible wire in this way. At the junction and intersection boxes the tube is carried in fully.

In fastening the tube to walls or beams either staples or brass clips are used, the latter being preferable, and in some places made compulsory by the Fire Underwriters. Where staples are employed they are driven by the staple driver, Fig. 4, provided for the purpose, thereby avoiding any chance of injury to the tube. The clip, Fig. 5, is recommended, as it is more easily used, and can be employed where difficulties are met with in fire proof buildings in driving home both legs of the staple. Its position may be easily lined out. A French nail is used to attach the clip to wall or beam, and after the tube is in position the tongue of the clip is pushed through the slot, provided for same, and drawn tightly by means of pliers. If desired, the ends of the clip may be cut off.

As a general rule, only six or eight lights are distributed from one tap, and the company prefer to use their flexible "twin conductor" for the branches with the two conductors in the one tube. Many details of feeder terminals, main and branch junction boxes have been worked out. In

Fig. 7.

Fig. 6 is a one-light bracket with locking canopy to fit a junction box, and Fig. 7 shows another variety of attachment in an ingenious spring ceiling pendant.

ELMORE'S COPPER DEPOSITING PROCESS.

Our readers will remember that about two years ago the Elmore process of copper deposition was brought out, which consists in depositing the metal upon rollers over which travel agate burnishers so that the copper as deposited is smoothed down and compressed.

The company formed to work these patents has made considerable progress since that time. Works of some magnitude have been acquired near Leeds, which leave room for extension. At present the plant laid down is capable of turning out five tons per week, and this is being increased at the moment to a fifteen tons capacity. Several samples of work that have been executed by the company, have recently been exhibited. These embrace specimens ranging from threads which have been passed cold through dies of $\frac{1}{1000}$ inches diameter drawn down from spirally cut sections to this dimension, up to pipes 18 inches in diameter and 14ft. long. Of the thread 40 miles in length go to the pound, and it looks like a bunch of hair, while the pipes shown are ¼in. thick, though the thickness may be increased to any desired extent. When it is understood that these results are achieved direct from Chili bars without any annealing whatever, and therefore without any detriment accruing from this operation, some idea will be formed of the purity. Specimens were exhibited that had been treated very severely, yet no harm had been done to the metal. It was as homogeneous as before it was touched. The invention accomplishes all this by eliminating the foreign matter always found with copper in its usual form. Up till now the company has confined its work to straight tubes of an even thickness, but the system admits of extra metal being deposited where required. If, therefore, a bend is necessary, it is proposed to take advantage of the irregularity allowed by this process to make the necessary shape.

CONTRIBUTIONS TO THE MOLECULAR THEORY OF INDUCED MAGNETISM.[1]

BY PROF. J. A. EWING, F.R.S.

AFTER referring to Maxwell's discussion of Weber's theory, which ascribes magnetisation in iron and other magnetic metals to the turning of molecules which are already permanent magnets, and to suggestions made by Profs. Wiedemann and Hughes, and lately by Mr. A. E. Kennelly,[2] the writer describes experiments which he has made directly bearing upon the molecular theory. The experiments were made by grouping near to one another a large number of small permanent magnets, each pivoted on a fixed centre, and by studying the manner in which the configuration of the group changed when external magnetic force was imposed. The results do not support the notion that the molecular magnets form closed chains in unmagnetised iron. They lead, however, to the important conclusion that no arbitrary conditions of directional constraint need be postulated to make the manner in which the molecular magnets turn agree with the chief features of magnetic quality. In the writer's view the molecular magnets are perfectly free to turn in response to external magnetic force, except in so far as they are constrained by the magnetic forces which they exert upon one another. He discusses this theory in a preliminary manner with regard to the form of the magnetisation curve, the character of cyclic processes, the effects of temperature, of vibration, of stress, and so forth, and shows that it is in general agreement with the known facts. The summary of conclusions is as follows :—

I. That in considering the magnetisation of iron and other magnetic metals to be caused by the turning of permanent molecular magnets, we may look simply to the magnetic forces which the molecular magnets exert upon one another as the cause of their directional stability. There is no need to suppose the existence of any quasi-elastic directing force, or of any quasi-frictional resistance to rotation.

II. That the intermolecular magnetic forces are sufficient to account for all the general characteristics of the process of magnetisation, including the variations of susceptibility which occur as the magnetising force is increased.

III. That the intermolecular magnetic forces are equally competent to account for the known facts of retentiveness and coercive force, and the characteristics of cyclic magnetic processes.

IV. The magnetic hysteresis and the dissipation of energy which hysteresis involves are due to molecular instability, resulting from intermolecular magnetic actions, and are not due to anything in the nature of frictional resistance to the rotation of the molecular magnets.

V. That this theory is wide enough to admit explanation of the differences in magnetic quality which are shown by different substances, or by the same substance in different states.

VI. That it accounts in a general way for the known effects of vibration, of temperature, and of stress, upon magnetic quality.

VII. That, in particular, it accounts for the known fact that there is hysteresis in the relation of magnetism to stress.

VIII. That it further explains why there is in magnetic metals hysteresis in physical quality generally with respect to stress.

IX. That, in consequence, any (not very small) cycle of stress occurring in a magnetic metal involves dissipation of energy.

THE NEW WESTERN UNION BUILDING.

The directors of the Western Union Telegraph Company held a special meeting on July 22, and were in session for an hour and a half. A long discussion of the fire and the means necessary to overcome its effects resulted in a decision to rebuild all above the fifth story. It was finally unanimously determined to construct four floors above the fifth, making the structure a nine-story building. In order to get still more room, the directors decided to build on the top of the building at No. 8 Dey street, which is owned by the company, and by means of the low roof of which the imprisoned employees were rescued during the fire. The reconstructed Western Union building will be plain and square, the present tower and ornamental top being dispensed with. As the Dey street building is twenty-seven feet wide and as deep as the present central building is wide, all the additional room that the company has been in need of for some time will be secured. The sixth floor will be used wholly for offices, in addition to the third floor, where the present offices are located. The seventh and eighth floors will furnish two operating rooms about 75 by 23 feet each. The Associated Press will have quarters on the seventh floor, in the new part of the building. The elevator in the Dey street building will run up to the ninth floor. The entrance to the Associated Press rooms will be on Dey street, as well as through the present building. The ninth floor will be occupied by a kitchen and restaurant for the employees. All the batteries and dynamos are to be located in the cellars of the building. The dynamos have been there for some time, although at one time they were operated up on the battery floor. The material of the new part of the building will be brick and iron, very much like that of the old portion. The time ball will be worked on top of the square roof, perhaps on a flag staff.

The directors gave General Manager Eckert full power to carry out their plans. J. B. Smith, builder of the present structure, will be engaged to do the work.

The work of tearing down the three upper stories will be begun immediately. The cost of remodeling and enlargement will be great, but no estimates have yet been made.

The relation of the New York business to that of the country, and the fact that the bulk of the Western Union's revenue comes from handling local messages, is shown by the reports from the test offices. It is the company's practice to receive reports each week from its central offices in all the larger cities of the United States. The business transacted by these offices amounts to more than half of the total business of the company, and their reports, therefore, afford an immediate and reasonably accurate index of the condition of the company's affairs. The reports for the week of the fire from the test offices, which are not directly dependent on New York for the bulk of their business, show almost the regular increase over the corresponding week of last year. In every city which is a business centre, with outlying towns dependent upon it, the bulk of the business is local. In the Mississippi Valley the company's business centres more largely at Chicago than in New York. For these reasons the returns from almost every test office west of the Alleghanies and south of the Potomac show a steady growth for the week ending last Saturday as compared with the same week in July, 1889. Of course, in the Eastern and Central States, where all except purely local business is more or less dependent upon New York, the company's work has been very greatly crippled. At the same time, the resulting loss is less than might have been expected. The company's entire business for the week was $10,000 ahead of last year. As the regular weekly increase is about $25,000, the effects of the fire, as shown by a falling off of $15,000 in the total volume of the company's receipts, have been comparatively insignificant.

THE KNOWLES STORAGE BATTERY.

We have recently had occasion to examine a new storage battery, the invention of Mr. E. R. Knowles, the well-known electrical engineer, who has had a large experience in the construction and manufacture of storage batteries, and in which many of the difficulties heretofore experienced in such cells appear to have been successfully overcome.

The new battery, as made by him, is novel and durable in construction, so that it will withstand mechanical and electrical shock without being disorganized or disrupted, or lose the active material out of its plates. In fact, as the plates are constructed, it would seem impossible for the active material to get loose or come out under any kind of ill usage. All liability of the plates to curl or buckle and injurious sulphating appears to be eliminated. The plates have a large storage capacity for their weight, and their efficiency is high. The cell is quite simple in construction, embodying several new features, and the support plates are unchangeable and unoxidizable. The cost of the cell has been reduced to a minimum, almost the entire method of construction being mechanical in its character, very little hand labor being employed.

A complete battery of these cells has been in active operation daily for the past eight months, subjected to very severe tests of various kinds, and successfully sustaining them all, the battery being in as good, if not better, condition now as it was when first set up ; and it would seem that the claims made by Mr. Knowles for his battery have been fully substantiated by its performance. In addition to this, the battery is made on a principle, covered by existing patents and others which are pending, which, it is claimed, places it outside the pale of present litigation, it being neither a battery of pasted plates nor a battery in which the active material is mechanically applied to the support plate. It is also claimed not to be a secondary-storage battery but a primary-storage battery, being constructed in such a manner as to be active when first set up, and hence able to give a current of electricity at once, without being acted upon by a current from some external source, thus saving time and expense in formation. Arrangements are now being made to place this battery on the market.

IN MEMORIAM—W. H. SNELL.

We have received from England a memorial pamphlet dedicated to the memory of Mr. W. H. Snell, the brilliant young editor of the *London Electrician*, who died this year only thirty-one years of age. It has an excellent steel engraving of Mr. Snell as frontispiece, and is a compilation of various testimonials as to his worth and work. The utterances thus included are from such men as Gisbert Kapp, W. M. Mordey, A. Reckenzaun, Guy Fricker, George Forbes, Oliver J. Lodge, J. A. Fleming and F. H. Webb.

1. Abstract of Paper read before the Royal Society, June 19, 1890.
2. THE ELECTRICAL ENGINEER, June 11 and 18.

CORRESPONDENCE.

CHICAGO.

Manufacturing in Chicago—Silicating Copper—The World's Fair Electrician—A New Electrical Organization.

THE announcement made recently of the sale of the Morgan tract, in Sec. 28, Calumet, has had already a marked effect on values in the vicinity. The property was held by the estate of D. S. Morgan. It comprises 477 acres. The price is $500,000. The significance of the sale lies in the fact that the ultimate purchaser is understood to be the Westinghouse Electric Company, and that the plans of the company contemplate the erection of large shops which will employ 1,500 men. The land purchased is considerably more than will be required for manufacturing uses, and a portion of it will probably be sold in lots, so that the cost of the land actually needed will be greatly reduced if not entirely made up from the profit of such sales.

The Washburn and Moen Company will soon begin to build its barb wire works on the land recently purchased near Cummings.

Mr. E. P. Wilson, of the Evanston Electric Light Company, will remove to Cincinnati, where he has been appointed commissioner of the Cincinnati Freight Bureau.

Mr. George G. Mullins, of Los Angeles, Cal., who is at present in Chicago, at the Leland House, claims to have discovered a method for silicating copper. He says:—"Electricians have always had an obstacle to combat for want of this method, which, by its purifying qualities, greatly increases electrical conductivity. By its means an absolutely pure copper casting can be made. When there is a flaw in a copper wire great annoyance results, and when that wire is in an underground conduit the annoyance and expense are greatly increased. Many experimenters have been searching for the method but without success." The method is understood to be thoroughly covered by patents.

The Chicago *Evening Post*, of July 21st, devotes a column and a half to electric work in Chicago, and the discussion of the merits of the gentlemen proposed for the appointment of electrician-in-chief of the World's Fair. Those informally proposed are:—Professor Elisha Gray, of Highland Park; Professor W. A. Anthony, of Manchester, Conn., and Mr. John P. Barrett, city electrician of Chicago.

An ordinance granting more time to the People's Electric Light and Motive Power Company of the town of Lake, has been vetoed by the Mayor.

A meeting of about 200 men employed in the construction departments of the electric light companies held a meeting last week at 167 Washington street and formed an organization. James C. Malloy was chosen temporary chairman and C. A. Roff, of the Chicago Edison Company, and E. Z. La Plante, of the Thomson-Houston Company, as secretaries. Addresses were made by Robert Nelson, M. T. Britzins, W. C. Pomeroy, James O'Connor and James Conrad, and all present became members of the organization.

CHICAGO, July 25, 1890.

PHILADELPHIA.

The Electric Lighting Interests of Philadelphia.—The Suburban Electric Co.—A Thomson-Houston Suit.

BEFORE many months the entire built up portion of the city will be strung with wires, and the gas works will be squeezed out of business by private companies making a better and cheaper light. There are eleven electric light companies furnishing light to consumers in this city, four others are preparing to enter the field, councils having granted them the authority to do so, and two more are awaiting the Mayor's approval of their ordinances to begin work. All the companies now in operation are as follows: Brush Electric Light Company; Northern Electric Light and Power Co.; United States Electric Light Company; Philadelphia Electric Lighting Company; Wissahickon Electric Light Company; Germantown Electric Light Company; Frankford Electric Light and Power Co.; Merchants' Electric Light Company, of North Front street; Frankford Avenue Merchants' Electric Light Company; Keystone Light and Power Company; Edison Electric Illuminating Company.

The following companies have secured their desired privileges and are preparing to begin operations:

Suburban Electric Light Co.; Powelton Avenue Electric Light Co.; Columbia Avenue Electric Light Co.; Cheltenham Electric Light and Power Co.

In addition to the above, councils have passed the ordinances of the Delaware Avenue Electric Light and Power Company and the Southwestern Electric Light Company, but the Mayor has not yet signed them.

The Brush, Northern, United States and Philadelphia Companies form what is known as the Electrical Trust. The United States has swallowed up the Maxim Company, while the Electrical Trust has gobbled up the American Sectional Underground Electric Light Company, and the Penn Electric Light Company's privileges have been absorbed by the Edison Company and the Electrical Trust.

It would appear that an understanding has been reached by representatives of different sections of the city by which the electrical franchises of all Philadelphia are to be divided upon a territorial basis.

The Suburban Electric Company, which will apply to Gov. Beaver for a charter on August 11, embraces Philadelphia, Bucks and Montgomery counties in its application, and is for the purpose of furnishing light, heat and power by electricity. Hamilton Disston, Charles A. Porter, William Miller, Thomas W. Smith and Peter E. Costello are named as the incorporators. Peter E. Costello said yesterday: "We have experimented and find that we can furnish light by electricity cheaper than gas, and we will not at present go further than to supply Tacony, but as several of our outlying towns, such as Foxchase, Somerton and Torresdale, lie close to the county lines of Bucks and Montgomery, we will make our charter to embrace these counties."

The Thomson-Houston Electric Company have filed two bills in equity in the Common Pleas against the Macon City and Suburban Street Railway Company, the American Life Insurance Company, and the Real Estate Title, Insurance and Trust Company. It is claimed that about September 26, 1889, the railroad contracted with the plaintiff to furnish electrical appliances for its equipment for which it was to receive 6 per cent. twenty-year bonds out of an authorized issue not to exceed $250,000 secured by first lien mortgage. The bonds were to be taken at 90 per cent. of face value. In February and May of the present year the plaintiff received 160 bonds as security for the payment of money due. The latter, when work is completed, will amount to $55,000. The plaintiff then states that after the original agreement between it and the railroad company had been executed that the railroad company "did procure to be certified and delivered by the trustee to it 260 of said bonds secured by said mortgages above recited;" and that the railroad company did, by its officers acting in its behalf, issue and deliver the said 280 bonds to the American Life Insurance Company without any consideration whatever, and in fraud of the rights not only of said railroad company as obligor and mortgagor, but also of the plaintiff. These bonds are now held by the assignee. The bill asks that the bonds be delivered up to a receiver to be held in accordance with the agreement, or if a consideration was paid for them that on the return of the consideration the bonds be returned to the company.

The Electric Engineering Co. have filed articles of incorporation in the Camden County Clerk's office. The objects are to construct electrical railways, cars, etc. Harvey Barton, Henry Gianella, Christian Schneider and Thomas Marion, of Philadelphia, and Charles Richter, of Camden, are the incorporators. The capital stock is $100,000, of which $5,000 is paid.

The report of the Philadelphia Local Telegraph Company for the past year shows the paid up capital to be $400,000. There are 142 miles of wire, and 60 stations. The gross expenses, including $31,000 in dividends, were $64,753.04, and the gross receipts were $63,861.06. The company has invested in stock of other companies $181,990.

PHILADELPHIA, July 25, 1890.

PITTSBURGH.

Electric Railway Franchises at Braddock—Electric Mining Work—Voltage for Electric Railways.

THE people of Braddock, Pa., have been in a fever heat ever since the numerous street car lines have been chartered, to know who would be successful in securing the rights of way through the borough. There are five corporations in existence, all clamoring for the plum, and on Monday evening, July 21, all presented their claims before a meeting of councils. It is safe to say that the historic halls of the Braddock council chambers never witnessed such a scene of wrangling and general disorder. Personalities were exchanged in a very profuse, though anything but a complimentary, style, and for a time it looked as if the city fathers in their wild endeavor to defend their own company were going to pull each other's hair. The affair apparently reached its climax when one councilman accused another of holding five thousand dollars' worth of stock in one of the companies, which made him more partial to its success than anything else. This announcement created a sensation, and councils adjourned in a regular stampede. This story has one moral which ought to be a good lesson to all street railroad men in the land, to wit: "Since the introduction of the electric motor, street railway companies are paying investments, and everybody tries to get the valuable franchises for running an electric road. Therefore, get up early and secure this right before you have four or five competitors, as in Braddock, Pa."

Another coal mine in the Monongahela coal valley is being furnished with an electric equipment for the production of coal, hauling of wagons, and also to light the mine. This time it is mine No. 1 of W. H. Brown & Sons, and the apparatus is said to be the Hercules mining machine, which is being operated very successfully in several mines already in connection with the Tesla motor of the Westinghouse Electric & Manufacturing Co.

The Postal Telegraph Company of this city is laying six additional wires East and three West of Chicago. A force of twelve local electric men, under Foreman Robert Daly, are now laying the wires each way from this centre.

Supt. Morris Mead, of the bureau of electricity in this city, has served a written notice on all the electric street railway companies, telling them that they must not charge their wires with an E. M. F. higher than 800 volts. Mr. Mead has stated that this rule has been established here and has to be observed by all electric street railway companies to ensure safety to the public from their wires.

PITTSBURGH, July 26, 1890.

ST. LOUIS.

Using Electric Power for Mining Work—Increasing the Municipal Co.'s Plant—Electric Railway Figures.

THE reorganized Gold King Consolidated Mining Company, owned by James Campbell and others of St. Louis, will use electric power to operate their stamp mills and other mining machinery. Water power will be utilized. A 300 h. p. plant will be installed at a cost of about $87,000.

The Municipal Electric Light and Power Company are putting in ten 60-light Wood arc dynamos to provide for additional lights required by the city and commercial demands.

The traffic of the Union Depot railroad has increased 35 to 40 per cent. since it has been operated by electric power. The gross receipts for June were $31,751.33 ; gross expenditures, $17,062.15.

Two 80,000 watt Short generators are being installed at the power station of the Short electric railway, on the south end of the St. Louis railroad.

ST. LOUIS, July 24, 1890.

REPORTS OF COMPANIES.

AMERICAN BELL TELEPHONE CO.

The Bell Telephone Company reports an increase in the net output of instruments for the month ended July 20. The returns show 468,234 instruments in use, an increase of 36,026 over a year ago. The movement of instruments for the month and since Dec. 20, is here given :—

Month July 20.	1890.	1889.	Increase.
Shipments	4,787	4,122	665
Returned	2,887	2,390	497
Net output	1,900	1,732	168
Since Dec. 20.	1889-90.	1888-9.	
Shipments	38,364	34,338	4,026
Returned	14,991	13,671	1,320
Net output	23,373	20,667	2,706
Instruments in use July 20	468,234	432,208	36,026

It is proper to look upon the growing use of the telephone as evidence of the growth of the country. The Bell company serves the whole country, and its instruments are indispensable business adjuncts.

NEW ENGLAND TELEPHONE CO.

The New England Telephone Company has declared the usual dividend of 75 cents per share, payable August 15, to stock of July 31.

The New England Telephone Company makes a report for the June quarter, to which is added the previous quarter's returns, completing the half year. Gross receipts have recorded a fair gain, but operating cost and construction charges have eaten up the whole increase, and the result is a decrease of surplus for both periods, as shown below :

Quarter June 30.	1890.	1889.	Increase.
Earnings	$347,410	$324,707	$22,703
Expenses	264,914	230,893	34,021
Net	$82,496	$93,814	*$11,318
Construction	18,123	17,924	199
Balance	$64,373	$75,890	*$11,517
Since January 1.			
Earnings	$681,449	$624,212	$57,237
Expenses	505,799	455,385	50,414
Net	$175,650	$168,827	$ 6,823
Construction	61,051	37,687	23,364
Balance	$114,599	$131,140	*$16,541

*Decrease.

AMERICAN BELL SEVEN PER CENT. BONDS.

"Rumors of rights soon to issue in American Bell Telephone," says the Boston News Bureau, "probably originate from the fact that on August 1 the company has the right to redeem the $2,000,000 debenture 7 per cent. bonds at $110 issued to stockholders at par Aug. 1, 1888. These bonds, which are really notes of the company, were drawn for ten years, with the proviso that it could redeem them at $110 in two years or on any quarter-day thereafter. Rights to take these bonds sold at $2 each, and were in the proportion of a $1,000 bond for five shares of stock or five rights. It is doubtful if these $2,000,000 bonds are called this August. A special meeting of the directors would be necessary, as no regular meeting will be held till after August 1. The interest on the $2,000,000 bonds now aggregates $140,000. This redemption would call for $2,200,000, and it is probable that at least $2,500,000 of stock would issue upon their being called for payment. The difference between the interest on the bonds and the dividend which the issue of stock would call for, would, if put into a sinking fund, redeem the principal of the bonds at maturity. But this plum to stockholders would undoubtedly be justified by the phenomenal financial condition of the company. The bonds now sell at $112."

STOCKS AND BONDS.

ST. LOUIS.—The Union Depot Railroad Company have authorized an issue of $1,000,000 6 per cent. 10-20 gold bonds, to be ready for delivery October 1st, and the Mound City Railway Company have authorized an issue of $525,000 6 per cent. 10-20 gold bonds for delivery at the same time. The St. Louis Trust Company is named as the trustees for both issues. The entire amount, $1,500,000, has been placed with James Campbell, broker.

THE LINDELL RAILWAY CO. have increased their capital stock from $800,000 to $2,500,000.

BIRMINGHAM, ALA.—The Birmingham Railway & Electric Co. will hold a stockholders' meeting on July 26, to consider the issuance of $1,500,000 of negotiable first mortgage consolidated bonds.

OTTAWA, CAN.—The Chaudiere Electric Light and Power Co. will increase its capital stock to $500,000.

SLATER, MO., has voted bonds for $7,750, to be spent for an electric light plant.

WINDSOR, CONN.—The Windsor Locks Electric Light Co. will increase its capital stock from $10,000 to $20,000.

DIVIDENDS.

MALDEN, MASS.—The Malden Electric Light Co. has declared a quarterly dividend of 2 per cent. It has increased its capital stock from $100,000 to $150,000.

SOCIETY AND CLUB NOTES.

THE MICHAELIS FUND.

A movement has been started to raise a fund for the benefit of the family of Major Michaelis, whose untimely death was mentioned a few weeks ago. Major Michaelis, whose death was due to his efforts to save one of his children from drowning, left a wife and six children, and, like most army officers, had been able to accumulate little. His widow has taken steps towards supporting her family herself, but some of the friends of Major Michaelis wish to raise a small fund, to be invested in a house or in some other manner for her. They take this step entirely without the knowledge of Mrs. Michaelis. The committee who have the matter in charge are Messrs. Shinn, Becker, Brush, Collingwood and Bogart, of the American Society of Civil Engineers; Pope, Martin, Wheeler and Phelps, of the American Institute of Electrical Engineers. Contributions may be sent to any of these gentlemen. Several hundred dollars have already been raised.

CAPE MAY MEETING OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. A. R. Foote, Secretary of the Association, has prepared a special circular with regard to the Cape May meeting, to be held August 19, and following days, and we quote the following items of information:—

How to Get There.

Pennsylvania Railroad from New York City to Cape May.
Daily except Sunday.
Leave New York 11 A. M., arrive Cape May 4.33 P. M.
Round trip ticket good for 10 days, $6.00.
Pullman palace car fare, one way, $1.00.

West Jersey Railroad from Philadelphia to Cape May, station foot of Market street, Philadelphia.
Daily except Sunday.
Leave Philadelphia 9 P. M., 2.30 P. M., 4 P. M.; arrive Cape May 11.15 A. M., 4.33 P. M., 6.10 P. M.
Sunday train—Leave 8.20 A. M., arrive 10.40 A. M.
Round trip ticket good for 10 days, $2.00.
Pullman palace car fare, one way, 50 cents.
Steamer Republic from Philadelphia.

Leaves Race street wharf every morning, including Sundays, at 7.30; arrives at Cape May Point about 1 P. M.

Round trip ticket, good for day of issue only, $1.00.

Fare one way, 75 cents.

The Way the Time will be Spent There.

Breakfast from 6 to 10:30.
Morning session of Convention from 10 to 12.
Bathing from 12 to 1.
Dinner from 2 to 4.
Afternoon session of Convention from 4 to 7.
Supper from 7 to 9.
Orchestral Concert or Hop from 9 to 11.

The Convention will meet in the large ball room of the Stockton Hotel, capable of seating 800. This room has been placed at the disposal of the association, by the proprietor, without charge.

During the dinner hours an orchestral concert will be given in the parlor adjoining the dining-room.

For the Evening Concert or Hop the orchestra and arrangement will be under the management of the Reception Committee. The services of an orchestra of ten pieces, Mr. B. L. Faeder, director, will be furnished by the proprietor of the hotel without expense to the association.

The Expenses While There.

Special hotel rates for members of the association, their families and friends :—

1 person per day.		2 persons per week.		2 persons for the Electrical Season.	
Annex room,	$3.50.	Annex room,	$10.00.	Annex room,	$50.00
Land view,	4.00.	Land view,	42.00.	Land view,	54.00
Ocean view,	5.00.	Ocean view,	50.00.	Ocean view,	64.00

The "Electrical Season" at Cape May will be from dinner on Saturday, the 16th, to include breakfast on Monday, the 25th. This secures nine days by the sea, with but seven business days.

Carriage hire, when secured at the hotel office :—

For 2 persons, single carriage without driver, $1.00 per hour.

For 4 persons, carriage, with or without driver, $2.00 per hour.

Bathing.—For use of bathing suit and dressing room, 25 cents for each person. No other charge.

Yachting.—Boat for 12, 3 hours for $3.00.

The Way to Secure Rooms.

Rooms have already been engaged for about 150 persons—members, their families and friends. As the hotel will accommodate 1000 persons, there will be no lack of room for all who come. The use of an elevator renders all floors about equally desirable. Still, those whose applications for rooms are first received will be accommodated from the largest range for selections. Those who know Cape May best are those who most cordially recommend every one who can do so to plan for a vacation during the "electrical season" and to spend it there with their families and friends.

Letters to engage rooms, should be addressed to:—

F. Theo. Walton,
Proprietor Stockton Hotel,
Cape May, New Jersey.

If a check is enclosed to cover the price of the room for the time and number of persons desired, a receipt giving the number of the room reserved will be sent by return mail.

LITERATURE.

"THE ELECTRICAL ENGINEER'S POCKET BOOK."

D. Van Nostrand Co., of 23 Murray street, will shortly issue "The Electrical Engineer's Pocket Book of Modern Rules, Formulæ and Tables," by H. R. Kempe. The work will have numerous illustrations, and will be sold for $1.75. The name of the author is sufficient guarantee for the appearance of a work of value that will be appreciated by all members of the electrical engineering profession.

AN ELECTRIC RAILWAY 42 MILES LONG.

Hon. C. H. French, of Seattle, Washington, passed through Pittsburgh on July 24, says a special dispatch, on his way to Washington. He is vice-president and manager of the Farmers' and Merchants' Bank of Seattle, but is lately devoting most of his time and attention to the building of an electric railway between Seattle and Tacoma, a distance of 42 miles. Mr. French said :

"The road when built, and it is now well under way, will be the longest electric railway in the world. Theorists and talkers have for some years been saying that electricity is the great motive power of the future. But the people of the East and the ones who do the most talking still stick to the steam railways. We of the West are going to put the electrical way to a practical test. The road will be a fair competitor of the steam railway and at a fair distance. The route takes us through several towns of 1000 to 3000 inhabitants and numerous smaller ones, but the most of the country along the road is farming land. It is very valuable, however, and one farm right on the route recently sold for $300 an acre. We expect to use the overhead system."

OBITUARY—JAMES W. QUEEN.

We regret to announce the death of James W. Queen, founder of the house of James W. Queen & Co., 924 Chestnut street, Philadelphia, on Saturday, July 12, at Cresson, Pa. Mr. Queen, who was about seventy-eight years old, had been failing for some time, and visited Cresson in the hope of receiving benefit from the mountain air. When a boy Mr. Queen entered the employment of John McAllister, then a well-known optician on Chestnut street. When McAllister retired, Mr. Queen, together with W. Y. McAllister and Walter B. Dick, succeeded to the business under the firm name of McAllister & Co. In 1853 this firm was dissolved and J. W. Queen started at 924 Chestnut street. In 1855 Samuel L. Fox was taken into partnership. The firm is now controlled by Samuel L. and Edward B. Fox. In 1868 Mr. Queen retired from business and traveled extensively, visiting nearly all civilized countries. Until last year he enjoyed excellent health. He leaves a widow, but no children.

In the business history of Philadelphia James W. Queen's name occupies a prominent place. His reputation was of the highest and he was noted for his integrity. Mr. Queen was very skillful as a manufacturer of delicate instruments for scientists, surveyors and chemists, and his reputation in that direction was world wide. He had for a long time past represented in this country the leading European makes of electrical apparatus for measurement, etc., and had lately gone into the manufacture of such apparatus himself. Many of the productions of the house in this department are already familiar to our readers.

OBITUARY—CLARK BEERS HOTCHKISS.

Few men were better known in electrical circles than Mr. Clark Beers Hotchkiss, the organizer of the district telegraph and messenger service system in this city, who died on July 24, at Paul Smith's, in the Adirondacks.

Mr. Hotchkiss was born in Auburn, N. Y., about forty-two years ago. At an early age he came to this city and for a time was engaged in the banking business. In 1871 he organized the American District Telegraph Company, and for many years held the position of its assistant secretary and treasurer. Leaving the older company in 1881 he organized the Mutual District Telegraph and Messenger Company, of which he was vice-president and secretary, and with which he maintained a connection to the time of his death. The success of both these companies was largely due to him. He was afterwards manager for A. G. Day's Kerite.

About two years ago Mr. Hotchkiss became afflicted with consumption, and since that date he has passed most of his time in various places among the Adirondacks in the vain endeavor to regain his health. His home in this city was for many years No. 60 East Sixty-sixth Street. He married Miss Porter, of Orange, who survives him.

Mr. Hotchkiss was a man of strong build and of equally strong will, and it was largely due to his assertive nature and marked capacity for executive work that the district messenger service took its place so quickly in the economy of city life. He was also, however, a man of warm heart and kindly instincts, and leaves a host of friends rich in reminiscences of his good will toward them.

AN INTERESTING ELECTRICAL PLANT.

A recent visitor to this city, Mr. Hawks, the general manager of the Salem-Winston electric road of Winston. N. C. gives an interesting account of the road just started there. This road, which is of the Sprague overhead system, went into operation on July 15, with two cars. Between 3 p.m. and 10 p.m. the cars had earned $57.65. Next day, with the partial help of another car, they ran the earnings up to over $100, making nearly 1000 passengers per car. Other cars are being added. The road is 4¼ miles long, laid with 45 lb. Johnson girder rail. The station is a composite one of unusual character. It comprises 3 Ball engines of 385 h. p. capacity. The electrical plant consists of 2 Edison railway generators, No. 20, of 50,000 watts each ; 4 Edison incandescents of 750 lights each, and two Brush arc machines of 45 lights each. The company has a long, exclusive franchise for light and power, and bid fair to build up in a short time one of the most lucrative businesses in the whole South. The towns of Salem and Winston lie immediately adjoining each other, and the population of 12,000 is chiefly engaged in the tobacco industry, which supports a number of large factories. The place also has many attractions as a health resort, and will soon have a large hotel, reached by the electric road, and lighted throughout by electricity.

LEGAL NOTES.

ELECTRIC LIGHT TOWERS—THE DETROIT BRUSH ELECTRIC LIGHT CO. vs. THE DETROIT ELECTRIC LIGHT AND POWER CO.

A case that has attracted much attention is that of the suit for an injunction brought by the Brush Electric Light Company to restrain the Detroit Electric Light and Power Company from employing towers similar to those used by plaintiff. The proceedings were had before Judge Brown. All the five claims of infringement were denied, with the exception of the central pole as a support for the skeleton tower. This the Judge thought might be patentable. Coming down to the question of granting or denying a preliminary injunction, the opinion was substantially as follows: "I think upon the whole that a preliminary injunction in this case ought not to be granted for the following reasons: First, because I am not altogether certain that the central post is patentable, or, if patentable, that it is infringed, although my present impressions are in favor of complainants upon both those points, but I can conceive it entirely possible that upon a more elaborate hearing of this case other devices may be shown which were anticipatory of this; or I may be able to sit in connection with the Circuit Judge, as this is a matter of considerable importance, where I should not hesitate to call upon him, as his opinion may differ from mine in regard to it. Although, as I said before, if this were a final hearing I should feel compelled, with the doubts I entertain about this case, to grant this injunction and not to accept a bond. I merely throw out this intimation as a hint to the defendants to accommodate themselves to the possible final disposition of this case. In the second place, I do not think this court ought to use the process of an injunction to break up this contract. I think the court ought rather to favor the contracts into which the municipality has entered, and not use the process of the court to break them down. In the third place, the granting of an injunction in this case would lead to very serious consequences, which would result not merely in the discontinuance of this central post, upon which, as I conceive, this whole case depends, but it would involve the stoppage of the use of the entire tower and the lamps placed upon that tower. At the same time, if this were a patent upon the lamps, and I felt as clear as I do about the question of central post, I should not hesitate to grant the injunction asked; or if it were upon the tower itself, I should make a like disposition of the case; but as it merely involves the support of the tower, and as the use of those supports in itself does no damage to the complainant, I think it would be an oppressive use of the process of the court to put a stop to the entire lighting of the city by this defendant company, simply because they have used, in defiance, it may be, a post which is an infringement upon the complainants' patents. Now, what shall be the result of this case upon a final hearing? The defendant may, undoubtedly, as it seems to me, avoid the effect of this patent by extending his parallel posts to the ground. And that form of it, I presume, may be done in a large number of cases. But, I suppose, he does not see fit to do that, and it would be a question of consideration whether we would enjoin him. I can only say that my present impressions are that if the case stands as it now does on final hearing, I shall be obliged to grant an injunction. I think, however, it is open to a fair argument as to whether this does involve invention, or whether this device is an infringement, and upon the whole I have come to the conclusion to deny the injunction.

"Both sides will be allowed three months in which to prepare for the final hearing on the question of whether the central post is patentable, and an infringement on the patent controlled by the complainants."

ELECTRIC STREET LIGHTING IN NEW YORK CITY.

The session of the gas commission last week was a short one, the board adhering to its position to hold the electric light companies down to the prices of last year. Contracts for 680 lamps have already been awarded at those rates. There are 209 lamps yet to be provided, as the companies hold out for higher rates for them.

The following letter from the East River Electric Light and Power Company was received and placed on file;—

NEW YORK, July 23, 1890.

Hon. Hugh J. Grant, Mayor, President of the Gas Commission.

SIR—The East River Electric Light Company asserts in the most positive manner that it derives no profit from the city lighting at 35 cents per night per lamp, and that it would be involved in a great loss if it attempted to do underground lighting at any such price.

It further asserts that no company or individual can supply lighting cheaper with the price of labor, coal and other commodities as they are in New York. We challenge a contradiction of this statement. Respectfully yours,

JOHN J. MOORE, Manager.

Commissioner Gilroy offered the following resolution:—

Resolved, That the contract for lighting all electric lights in the city of New York, bid for on July 14, 1890, be, and the same is hereby awarded to the companies bidding, in so far as the prices bid correspond with the prices bid for lighting the city last year, until the 1st day of January, 1891, and that the secretary of this board be directed to notify the various electric light companies of the acceptance of such bids.

This was unanimously adopted, as were these succeeding ones offered by Mayor Grant and Commissioner Myers, respectively:—

Resolved, That the commissioner of public works be authorized to confer with the several electric light companies whose bids exceed the amounts paid last year, with a view to obtain such electric lighting as may come within the appropriation for the year 1890, and report to the gas commission the result of such conference at as early a date as possible; and,

Resolved, That the secretary is hereby directed to notify the several electric light companies that this board will not consent to permit the lighting of electric lamps at rates in excess of the prices fixed in the late contracts which expired on April 30, 1890, owing to the fact that the appropriation for lamps and gas and electric lighting will not admit of the lighting at rates in excess of the rates fixed in the late contracts.

After authorizing Superintendent McCormick to confer with the companies concerning the lighting of Stuyvesant Park, west, the board adjourned.

METAL AND SUPPLY MARKET.

THE UPWARD TENDENCY OF COPPER.

During last week the nominal price of copper on the Metal Exchange exceeded the highest figure reached by the syndicate in its palmy days, the quotation of July 23 being 16.90c. The electrical demand for this metal steadily increases and greatly strengthens the position of large holders. Prices bid during the week were as follows:—

21	22	23	24	25
16.75c.	16.80c.	16.90c.	16.50c.	16.80c.

The official circular of the Metal Exchange gives the following compendium statement of sales at which margins were called;—

	July 25.	July 18.	July 26, 1889.
Straits tin, spot	20.90	21.80	19.60
Straits tin, Oct	21.00	21.10	19.70
Lake copper, July	16.90	16.75	11.50
G. M. copper, July	—	—	9.00
Domestic lead, spot	4.45	4.50	3.87½
Domestic spelter, July	5.45	5.50	5.10

INVENTORS' RECORD.

Patents issued July 22.

Alarms and Signals:—*Station-Box for Watchmen's Electric Time-Detectors*, J. E. Richards, 432,645. *Apparatus for Indicating Races*, G. H. Chappell, 432,694.

Conductors, Conduits and Insulators:—*Telegraph Pole*, C. M. Brush, 432,858.

Dynamos and Motors:—*Brush Reverser for Electric Motors*, A. Reckenzaun, 432,561. *Dynamo-Electric Machine*, H. W. Spang, 432,577. *Frog for Overhead Wires*, E. Thomson, 432,581. *Welding or Other Dynamo*, E. Thomson, 432,652. *Dynamo-Electric Machine*, E. Thomson, 432,655. *Electric Motor*, H. Humbert, 432,707. *Armature for Dynamo-Electric Machines*, N. H. Edgerton, 432,748. *Automatic Lubricating Device for Electric Motors*, S. L. Barriett, 432,927.

Galvanic Batteries:—*Battery Cell*, H. E. Waite, 432,681.

Ignition:—*Electric Gas Lighter*, J. H. Lehman, 432,884.

Lamps and Appurtenances:—*Filament for Incandescent Electric Lights*, L. N. P. Poland, 432,710. *Electric Lighting System*, E. T. Cooke and W. H. Mackay, 432,745. *Electric-Light Shade*, J. H. Goehst, 432,896. *Arc Lamp*, A. H. Lucas, 432,949.

Measurement:—*Electric Meter*, E. Thomson, 432,654.

Metallurgical:—*Magnetic Separator*, G. S. Finney, 432,823.

Metal-Working:—*Electric Metal-Working Apparatus*, H. Lemp, 432,629. *Forming or Shaping Metals by Electricity*, H. Lemp, 432,630. *Method of Working Metals by Electricity*, E. Thomson, 432,651. *Method of Welding Pipes by Electricity*, E. Thomson, 432,653. *Manufacture of Bands, Rings, etc., by Electricity*, E. Thomson, 432,656. *Method of Electric Riveting*, M. W. Dewey, 432,727.

Miscellaneous:—*Electric Stop-Motion for Looms*, D. E. Coughlin, 432,512. *Electric Cut-Out*, S. D. Field, 432,521. *Phonograph*, J. P. Magenis, 432,886. *Rheostat*, T. J. Parrish, 432,894. *Heating by Electricity*, W. L. Burton, 432,962.

Railways and Appliances:—*Conduit System for Electric Railways*, N. Seibert, 432,571. *Electric Railway*, R. M. Hunter, 432,623. *Current and Switch Controlling Mechanism*, E. W. Rice, Jr., 432,644. *Motor for Electric Railways*, M. H. Smith, 432,646. *Electric Lighting of Railway Trains*, J. A. Timmis, 432,657. *Conduit Electric Railway*, B. Jennings, 432,670. *Electric Railway*, F. Mansfield, 432,673, 432,674 and 432,675. *Electric Railway*, R. M. Hunter, 432,752 and 432,753. *Conduit Electric Railway*, B. Jennings, 432,941.

Secondary Batteries:—*Method of Making Secondary Battery Plates*, W. P. Kookogey, 432,672. *Method of Forming Secondary Battery Plates*, H. G. Morris, 432,834.

Telegraphs:—*Electrical Communicating System*, A. G. Holcombe, 432,618. *Call-Box for Electrical Signaling Systems*, A. G. Holcombe, 432,619. *Automatic Adjuster for Telegraph Lines*, C. P. Carr, 432,724.

Telephones and Appliances:—*Telephone Exchange*, J. A. McCoy, 432,547. *Support for Telephone Hearing Trumpets*, S. Lebenberg, 432,883.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

THE PAILLARD NON-MAGNETIC WATCH COMPANY.

The above company has recently been organized, and has fitted up very handsome offices in the Corbin Building, on Broadway and John street. Its officers are: W. W. Hammond, president; C. P. Bruch, secretary and treasurer, and A. C. Smith, general selling agent. It has just issued the following important circular:—

On the 15th day of February, 1890, by order of the Supreme Court of the State of New York, the Non-Magnetic Watch Company of America was dissolved, and a receiver appointed to liquidate its affairs. As is well known to the trade, that company had, at the expenditure of many hundreds of thousands of dollars, organized and equipped factories for the manufacture of watches and watch movements containing the inventions of Paillard; these watches have obtained so high a reputation among the trade that no reference to them is deemed necessary. Upon the abandonment of its business by the Non-Magnetic Watch Company of America, for reasons which are of no general interest except that they are in no way connected with the success of said inventions, the Paillard Non-Magnetic Watch Company was organized under the laws of the State of Illinois for the purpose of continuing the manufacture and sale of non-magnetic watches containing Paillard's inventions. This company has purchased from the manufacturers, the movements in process of manufacture at the time of the suspension of the Non-Magnetic Watch Company of America, and has acquired the manufacturing facilities formerly possessed by that company. The movements to be placed upon the market by the Paillard Non-Magnetic Watch Company will be manufactured by the same factories, contain the same inventions and be practically the same as those heretofore sold by the Non-Magnetic Watch Company of America. New grades will be added from time to time as required.

The Paillard Non-Magnetic Watch Company are licensees under the Paillard patents and no other organization possesses the right to use them. The factories having passed through the experimental stage, all movements sold by this company will be of the newest models and contain the latest improvements. Every movement is warranted and prices guaranteed.

Mr. A. C. Smith, formerly with the Non-Magnetic Watch Company of America, will continue as the general selling agent of this company.

THE NEW LIQUID INSULATING PAINT, "SEALINE."

Never before was the necessity of good insulation realized as it is now, and as a consequence there has arisen a demand for just such a compound as that now put upon the market by the Seely & Taylor Manufacturing Co., of 24 Cortlandt street, under the name and trade mark of "Sealine." This striking piece of nomenclature is a punning play upon the name of the inventor, Mr. John A. Seely, whose long familiarity with the requirements of telegraphy, telephony and electric lighting has given him an experience he has now turned to the common advantage. "Sealine" is a liquid insulating paint, which is cheaper, it is said, than other compounds intended for use in the same way. It has no bad odor, and is absolutely fire-proof as well as oil-proof. The company have already received large contracts for it, one of them being for the painting of metal roofs. It has also been found extremely useful for converter boxes, lamp hoods, moldings, etc. We have had the opportunity of examining various substances to which it has been applied, and find it to be very flexible and tenacious, neither cracking nor wearing off. We have also seen samples of ordinary underwriter's wire, to which it has been applied with excellent insulating effect. It is put up in tins, etc.

ELECTRIC CAR GEARING AND ELECTRIC ELEVATORS.

Chadbourne, Hazleton & Co., of Philadelphia, have sold to the Wenstrom Consolidated Dynamo & Motor Co., of Baltimore, Md., their patent noiseless gearing for electric street railways. This gearing will be manufactured by the Wenstrom Co. at their Baltimore factory. Chadbourne, Hazelton & Co. will be the General Selling Agents for these gears for the United States. They have also sold their patents for their electrically actuated elevator to the Wenstrom Co., by whom these elevators will be manufactured. Chadbourne, Hazelton & Co., will be the General Selling Agents for the United States.

THE ROBERTS STORAGE BATTERY AND ELECTRIC CONSTRUCTION CO.

A corporation with the above title has been formed recently in Canada to manufacture the storage battery invented and patented by Mr. W. Roberts. The company has offices at 46 Adelaide street, West, Toronto, and Mr. G. H. Macfadane is manager of the Canadian department. For his battery Mr. Roberts claims a larger output per pound of plate than can be safely drawn from any other cell. His plate is of peculiar construction, consisting of two cast plates made of a special alloy, and the active material is so held that it cannot drop out. For the heavier grades of work, a third intermediate plate is used with the two outside shells. Mr. Roberts has also a special and simple form of connection between cells so that they may be connected or disconnected in a moment. The cell is intended particularly for street railway work, and the tests made with it yield very satisfactory results.

THE EDISON INDUSTRIAL WORKS.

The Edison Industrial Works have filed articles of incorporation in the Essex County Clerk's office. Silver Lake is to be the principal place of business in New Jersey, but the company will have offices in New York and other States. The company is to manufacture, buy, sell, lease, and use machinery for mechanical, scientific, mining, and chemical purposes, and to purchase mines, factories and other property. The capital stock is to be $1,000,000, and the company intends to begin business with $150,000. Thomas A. Edison and Samuel Insull, of Orange, and Thomas Butler, of New York, are to be the incorporators.

THE UNITED ELECTRIC CO.

A recent organization is the United Electric Co., which has been formed in Cleveland, with offices in the Society for Savings Building. The company intends carrying on a general business as electrical engineers, manufacturers, agents, etc., but has a special agreement with Mr. W. E. Irish, who is known very generally in England and America as a prolific and meritorious inventor, to manufacture under his valuable patents. Mr. Irish has left scarcely a field of electrical work untouched, and has brought out telegraphs, telephones, arc lamps, incandescent lamps, motors, dynamos, street railway systems, conduits, etc. The company has incorporated with the modest capital of $50,000, and with the following officers:—W. E. Irish, president; T. D. Owen, vice-president; O. J. Campbell, assistant secretary and treasurer. With these, as directors, is associated Judge J. C. Hutchins.

THE ACCUMULATOR CO.

Under the fitting name of "The Accumulator Company," the interests represented by the Electrical Accumulator Co. have been re-organized. Mr. T. N. Vail is the president of the new corporation; Mr. D. H. Bates, vice-president and general manager; Mr. Charles R. Truex, assistant general manager; Mr. H. R. Parrish, secretary and treasurer. The company will carry on the business as before at 44 Broadway, and will be represented on the Pacific Coast by the Pacific Electric Storage Co., of San Francisco. Six storage cars have just been sold to Dubuque, Ia.; also 58 cells of 15 L type to F. M. Johnson, of Grant's Pass, Ore.; 36 cells of 15 L type to San Francisco, and 30 cells of 15 M type. The company are now prepared to fill the largest orders.

EDISON-LALANDE BATTERIES IN THE WESTERN UNION BUILDING.

The recent fire in the Western Union Building in this city, as our readers are aware, completely wiped out the battery plant, including both mains and locals. Recognizing the value of the Edison-Lalande Battery, especially for local work and its superiority over the ordinary blue-stone cell for this purpose, the Western Union Company late on Saturday afternoon, the day after the fire, ordered twenty cells from the Edison Manufacturing Co. It was too late to get anything expressed that day, but with his characteristic energy, Mr. James F. Kelly, general agent of the company, had the cells brought on from the factory by wagon, accompanied by Mr. Gladstone, superintendent of the factory, who set them up in the Western Union Building that same night.

On the following day 50 more were delivered and since then about 280 cells have been set up. These have replaced over 1600 cells of ordinary blue-stone battery, which would have been necessary.

The rapidity with which the Edison-Lalande battery can be set up and its immediate readiness for maximum work were thus brought out with great prominence on this occasion, and the promptness of the Edison Manufacturing Company in meeting the demand made upon them was no doubt appreciated by the Western Union authorities.

THE COLUMBIA INCANDESCENT LAMP CO.

The above company, of 1912 and 1914 Olive street, St. Louis, Mo., report that they are just completing arrangements to increase their capital stock. They will also enlarge their factory in order to keep pace with the growth of their business.

NEW ENGLAND TRADE NOTES.

THE PROVIDENCE CONSTRUCTION COMPANY, Providence, R. I., are at present engaged in wiring the Sakonnet Hotel, at Seaconnet Point, R. I., for a complete system of annunciator work.

MR. W. J. PILICY, agent for the Card Motor Company, of Cincinnati, has taken a new office at 74 Federal street, Boston, having removed from his old quarters at 146 Franklin street. The new office is on the ground floor, and the windows on Federal street offer a rare chance for the neat display of motor service.

MR. D. MURDOCH, traveling agent of the Baxter Electric Motor Company, of Baltimore, for the Eastern States, is paying a visit to the New England States this week, for the purpose of looking up Baxter motor interests and establishing agents. Mr. Murdoch makes his headquarters, while in Boston, in the office of Mr. Frank Ridlon, 196 Summer street, who has long been identified with the interests of the Baxter Motor Company.

THE STANDARD ELECTRIC COMPANY OF VERMONT have replaced the old Forsyth dynamo in the mill of the Franklin Falls Pulp and Paper Company, at Franklin Falls, N. H. The Forsyth dynamo was bought out by the Standard Company some years ago, but never gave good results, and is not to be confounded with the Standard dynamo, which the company are now selling, and which is vastly superior. They are gradually changing all the Forsyth dynamos wherever they can induce the user to bear the expense of the change.

THE AMERICAN ELECTRICAL WORKS, Providence, R. I., are having a continued run of good business, and in order to promptly meet their largely increasing orders, are making arrangements for a large increase to their factory. The addition will be 40 feet by 125, and will be five stories high. At present there are about 875 employees at work, and the new wing will give employment to about 300 more. The American Electrical Works are making a great specialty of very fine magnet wires, and do all their own drawing by special machinery for sizes under No. 18, and are justly celebrated for the uniformity of the diameter of these fine wires. In past years the American Electrical Works used to import the fine dies necessary for drawing the wire, but from persevering experiments, Mr. Sawyer informs me, they are now able to make the finest dies themselves. I recently saw a sample of German silver wire specially drawn and double covered with silk, to form a megohm resistance, which resembled a fine hair, and was undoubtedly a beautiful specimen of delicate work.

THE ROBINSON RADIAL CAR CO. have recently supplied the West End Street Railway Company with a new open car with twelve seats to hold 60 passengers, and it is now being regularly used on the Cambridge road, and runs around 30 foot curves with the utmost ease. The car is fitted with their new standard steel trucks, with a 14-foot wheel base, and is giving great satisfaction, riding extremely steadily and easily. They are at present engaged in building 14 more cars for the West End Company. These will probably be closed cars, as they could not be got ready for summer use, though the trucks can be used either for closed or open cars. The Thomson-Houston Electric Company have also ordered 25 radial cars with 14-foot wheel base. The Robinson Radial Car Company have just shipped an elegantly furnished electric car of the same type to the Eckington and Soldiers' Home Railway in Washington, D. C., which will be the most commodious and most luxuriously furnished and easy riding car that has ever appeared in the streets of Washington.

THE TROPICAL AMERICAN TELEPHONE CO. has acquired the sole interest in the "Hynes" annunciator drop, known throughout the United States as the "*Williams*" switch-board drop. This patent was only issued in April last, and has been pending since 1882. It covers all the drops in the "Williams" switch-boards, Mr. Howard says, and is destined to be quite a factor in the company's financial affairs, as Mr. Hynes admits that he has helped to manufacture over 35,000 of them while in the employ of Charles Williams, Jr. There are thousands of them scattered throughout the New England Telephone Company's territory, and their licensees will now, it is said, be asking how it is they are expected to pay another concern for a device sold them but not owned by the seller. The Tropical American Telephone Company, I am informed, can now manufacture its own switch-boards free of royalty and exact royalty from others for the further use of each of these drops, and these users are now being notified to discontinue their use. Mr. James Howard also hands me the following:

"The Tropical American Telephone Company wishes exporters to take notice that it is the sole authorized agent of the Inventors Bell and Blake, and no one except with its permission is allowed to sell any American Bell telephone excepting as the true destination is stated. The company, hereafter, will insist upon delivering the telephones on board the steamer which is to take the instruments abroad. The company is the sole assignee of the Hynes patent covering the "Williams" annunciator drop, and will hereafter fill all orders for "Williams switch boards" direct instead of through any other manufacturer."

WESTERN NOTES.

THE WESTERN POWER CONSTRUCTION CO. have now got settled in their new offices, and report business as rushing. They have taken orders in the past three weeks aggregating more than 1000 h. p. for complete steam plants.

MR. FOREE BAIN has just completed designs for a new motor equipment for street car work, which possesses some very advantageous features, and appears to be quite a step in advance in this line. The machines will be built right away, when their actual working will be practically tested.

COL. J. H. SHAY, of the Charles Munson Belting Company, has just returned from a trip East. He has come back as usual with his pockets full of fine orders, and he reports the demand for Munson belting on the increase all the time. This is entirely due to the remarkably fine quality and durability of their product.

MR. L. W. COLLINS, now the general sales agent of the Electrician's Time Company, 167 Dearborn street, Chicago, and formerly manager of the Chicago Electric Club, reports business as first-class and coming in to the new company from all sides. We cannot wonder at this, as the sales department is in the hands of so popular a worker as Mr. Collins.

THE HAZELTON TRIPOD BOILER COMPANY are erecting a new boiler in the cable road power house at 61st and State sts. The peculiar construction of these boilers makes them specially suited to their work, which they perform with the most universal success, and they are giving the greatest possible amount of satisfaction whereever they are in use.

MR. W. P. SULLIVAN has accepted a position as assistant to Mr. Albert Blanchard, of The Pond Engineering Company, who are doing a very extensive business in building electrical and power plants. They now have offices in most of the large cities, and will shortly open branches in other parts of the country. The company and Mr. Sullivan are to be mutually congratulated on the connection.

MR. C. H. CONE has just sold a carload of Laclede carbon batteries numbering some 5000 cells to The River and Rail Electric Company of Denver. Mr. Cone is going to place in his offices at 103 Adams street, right away, a full sample line of the famous Baxter motors, which will enable him to demonstrate on the spot to intending purchasers their many advantageous points and merits.

MR. W. R. MOLINARD, general sales agent of the Baxter Electric Motor Company, of Balkin, Ore., has been in town looking after the Chicago interests of the company. He has placed the agency for their well-known motors in the hands of Mr. Charles H. Cone, and has now returned East. He says things are looking remarkably bright with them, and they shortly expect to place some new departures in motor work on the market, which will be undoubtedly in enormous demand.

THE ILLINOIS ELECTRIC MATERIAL CO., The Rookery, Chicago, dealers in electrical supplies for electric light power and railway work, and Western agents for the Bishop White Core wires and Balata cord and the "Trinidad" moisture proof wire, have recently received some fine orders. Mr. Hoefer, the vice-president and manager of the company, has just returned from a trip in the North West, in which he caught plenty of business. Mr. E. L. Clark, the secretary, of pole-fame in Chicago, is all the time around getting orders for poles, ties and cross-arms.

THE GREAT WESTERN ELECTRIC SUPPLY CO. have the exclusive agency for the United States for electroliers made of all kinds of animals. The Elk Head electroliers at their Chicago store have already attracted much attention, and other novel features are promised by them. They are building some special racks for showing their stock of colored and cut-glass shades, of which they have the largest and finest assortment in the country. In response to the description of the Pattee Lamp Hour Recorder in the papers two weeks ago, letters are now received from all parts of the country; this shows the need of a simple meter. The specialties put out by the firm are set forth in a half dozen special circulars, all uniform in size and neatly gotten up in different colors. The series is being added to week after week and will supplement their preliminary catalogue now in the hands of the printers.

ST. LOUIS TRADE NOTES.

THE NORTH AMERICAN CONSTRUCTION CO.—St. Louis office—have contracts on hand for the equipment of 10 miles of Westinghouse electric railway at Springfield, Mo.; also an electric light plant of 1,500 incandescent and 120 alternating arc lights at the same place. They also have contracts for the installation of 715 incandescent and 40 arc lights for the Lebanon light and Water Co., Lebanon, Mo.; and 750 incandescent lights for the Belleville Electric Light and Power Co., Belleville, Ills.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, AUGUST 6, 1890. No. 118

The neglected borderland between two branches of knowledge is often that which best repays cultivation.—Lord Rayleigh.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

FOR the first time in its existence, the National Electric Light Association seeks the seashore. It is true that summer meetings have been held by it in New York and Boston, with little incidental seaside trips, but not before this year has the Association boldly and wisely planted its standard by the sea. It now bids all its friends and members welcome to the "summer capital," as Cape May proposes to be called.

This choice of a seaside resort is in many respects excellent, and the place itself is one of the best in the country for the purpose. Besides, there is no reason why the convention should not accomplish more work even than if it were called together in a hot and sweltering city with every condition adverse to either physical or mental activity. That the convention will be profitable and productive of good results is indicated by the length of the programme printed in our pages this week and by the nature of the topics to be brought up. Some of the papers deal with the most vital questions connected with central station management, and should invite to earnest and exhaustive discussion. Other papers and business relate to the functions of the Association itself, and nothing is more desirable than a thorough ventilation of all the matters that concern the duties and opportunities of such an important body.

Central station companies are not yet fully alive to the good they can derive from the work of the Association. If they were, the membership would be many times larger than it is. Every company of any size should be represented in its ranks and should participate in its gatherings. Each manager or superintendent has something to contribute to the fund of information and possibly something to learn; while his adhesion and support give to the work and declarations of the body the authority they need as the expression of the judgment and experience of the whole industry. The Association has done work to be proud of; it has lived down various troubles and difficulties, and it should be the common aim of all, whether local companies, parent companies, or dealers in apparatus and supplies, to give it a larger and higher influence.

ELECTRIC RAILWAYS AND OCEAN CABLES.

IT was hardly to be suspected that the disturbances caused by the introduction of electric railways would extend farther than their effects on telephonic transmission, but a recent development in another direction now claims attention, as well from the distance apart of the affected circuit and disturbing wires as from the fact that the former is a complete metallic circuit. As Mr. Cuttriss shows, the Commercial Cable Company's cable communication between this city and Coney Island is sufficiently troubled by the wires of an electric railway at a distance of half a mile to introduce false signals and to interfere seriously with testing operations. But the fact that a complete metallic circuit is employed seems to point to the conclusion that the trouble is due to conduction, or leakage, rather than to induction. True, the insulation is over 350 megohms per mile, but the potential employed on the railway, 500 volts, might be sufficient to affect, even by leakage, the delicate recorder and the still more sensitive Thomson astatic galvanometer. As yet the disturbances noted are not sufficiently great to impede the cable traffic, but Mr. Cuttriss hints at the possible consequences of an electric railway run over the same route taken by the cable. There will, of course, be a solution for the difficulty, but it will be interesting to see just what it is.

MAKE AND BREAK TELEPHONY.

THE controversy regarding the possibility of transmitting articulate speech by means of a make and break telephone, which a few years ago was carried on with considerable warmth, has now almost died out, but there remain still a few smoldering embers of those fires and they are fanned into flame from time to time by the ever-restless inventor. A somewhat novel departure in the lines heretofore worked on in this direction, and one that may revive the discussion, is exhibited in the make and break transmitter of Mr. S. D. Field, which we describe elsewhere in this issue. Mr. Field employs the makes and breaks independently of the vibrations imparted to the receiving diaphragm, and hence his apparatus may be considered a combination of a transmitter with a high speed circuit breaker. The apparatus recalls a kindred one introduced in evidence in one of the Bell suits, in which the possibility of transmitting articulate speech by means of a make and break current was demonstrated by passing the current through a rapidly revolving make and break switch. Unfortunately for the defendants, however, the demonstration was considered by the judge to have been successful, not on account of, but "in spite of," the make and break character of the current.

The judge evidently thought it more meritorious to do a thing well than to do it badly. Mr. Field, however, may consider himself clear of such a cynical criticism and all that it implies.

A Novel Burglar and Fire Alarm System.

Not a little ingenuity has been expended in the past in devising means for the protection of buildings from the invasion of unauthorized persons. These burglar alarm systems, however, have followed very much the course taken by the manufacturers of safe locks. The contest is a continual one between the burglar and the protective company, and as each improvement introduced is surmounted by the lock picker, the safe maker is obliged to introduce another in order to guard against invasion. The application of resistances as a protective and indicating measure for such systems has been made before, but a very interesting modification in their application is that described in another column, due to Mr. A. C. Robbins. By the application of the Wheatstone-bridge principle and the placing of a miniature fac simile circuit within the central station to represent the condition on the lines, he is able to locate at once any interference or abnormal condition, and the arrangement is such that by no conceivable method is it possible to keep the station in ignorance of the tampering with the circuit. This valuable addition to the protective methods, as well as its application for fire alarm purposes, seems destined to come largely into practice.

New Types of Tesla Motors.

Since Mr. Tesla read his classical paper on alternating current motors before the American Institute of Electrical Engineers, in 1888, he has devoted considerable time to perfecting these machines, and as a result has produced numerous forms, which, though having a distinct individuality, are but developments of the original idea embodied in that paper. In the present issue we describe a number of interesting forms of these later types which demonstrate particularly various interesting ways of operating these motors from a single source of alternating current by the use of two wires only. In these forms, it will be noted, Mr. Tesla obtains the necessary phase difference by shielding one of the circuits by a thin film of iron, either in the motor or in a transformer used in connection with a motor.

The River and Rail Electric Storage Car System.

The word "system" as applied to electrical apparatus in general has long since lost the force it once possessed when but few workers occupied the field and each one worked out his ideas in a manner possessing distinct individuality. In employing the word as above, however, its old meaning is recalled to us in considering the methods employed by Prof. Main in his electric traction system, which we describe at length elsewhere in this issue. Prof. Main has started out on individual lines, not only in the construction of his cells, but throughout the motor, its gearing and the other details. As will be noted, he has taken up the zinc-lead storage cell and claims to have successfully overcome all the difficulties heretofore experienced with that type, by placing the plates in a horizontal position instead of vertically. This is an interesting fact and the reasons for its adoption seem to be well grounded in observed phenomena. Prof. Main's motor is also worthy of study as embodying a type of machine which is likely to come into some extensive use, not only for continuous current work, but also for alternating. The advantages of a single magnetizing coil must be obvious, not only in regard to the cheapness of construction, but also to the uniformity of field produced in all the pole-pieces. Again, the car gear and its method of connection contains many points of novelty, and while in itself it is exceedingly simple, it is capable of meeting a variety of conditions which are of the highest importance to the economic operation of street railway cars.

Constant Current Transformer.

As remarked elsewhere on this page, Mr. Tesla has employed a special type of converter in order to obtain the necessary phase difference in his motors, but an interesting application of this type of converter is the maintenance of constant current with varying loads on the secondary. No special rules are given for the construction of this form of converter, but the general principle is described with sufficient clearness to afford a ready guide to the construction of such devices.

The Western Union Fire.

"Fine words butter no parsnips" is the blunt expression of a homely truth, and perhaps a little too harsh for the occasion, but it comes to mind as one reads the glowing terms in which General Eckert and Mr. Tinker praise their staff for the work done by it after the late fire. The compliments paid the men are graceful and evidently sincere, but seeing that many of the men lost their personal effects, while others who have been working night and day are really out of pocket by their extra work, it is only reasonable to suggest that a more tangible acknowledgment might also be made. The Western Union has lost nothing by the fire; it has, in fact, been given the chance to effect improvements that have been in mind for years, and that, when made will bring large economies in their train. Patience and loyalty are their own recompense in any employ; but where the resources are so great as are those of the Western Union Co., and where the benefit of the zeal of the staff is so immediate to the company and the public alike, substantial marks of appreciation would be proper and in order. We venture to put forward the suggestion that as medals and pensions are out of the question, a few silver dollars would not go amiss as the reward.

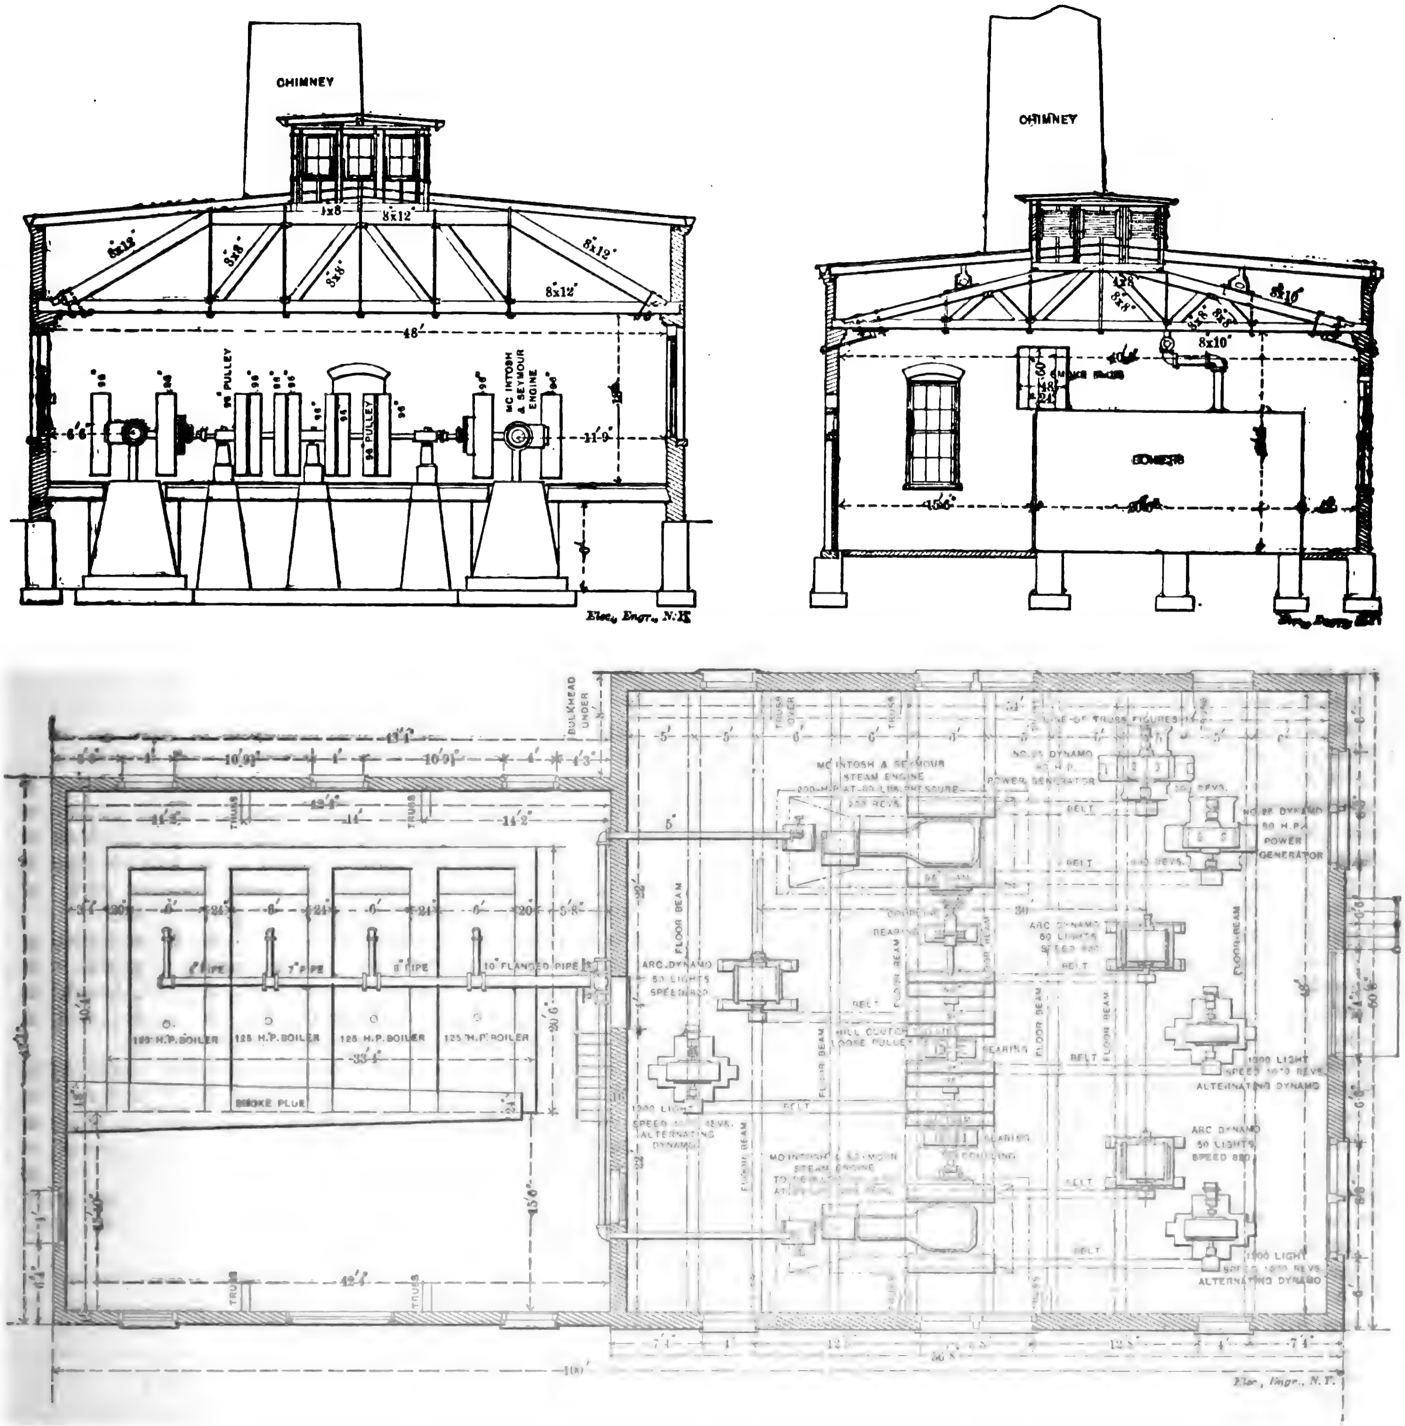
Electricity as a Scapegoat.

Mr. Wm. Maver's pithy little letter in this issue shows how silly and baseless are the accusations so often brought against the electric light wires. Another example would be the recent fires in the old Western Union building at 145 Broadway—both within a week. The first fire, in a waste paper closet, was gravely attributed to the wires. In their reports of the second fire, the papers make the statement with due seriousness that there were no wires at all in the building or in the places where the fire started. It is a pity they did not know this when in the first instance they located the wires in the waste paper closet—one of the oddest locations in the world.

NEW ELECTRIC LIGHT STATION AT NATICK, MASS.

We illustrate this week the new electric light station using the Thomson-Houston system, at Natick, Mass., which possesses some novel features in the method of driving from the engines to the dynamo. There are only a few of the more recent stations operated on the same principle, and no illustration has, until now, been published showing the details. The station was designed for 500 horse-power, though the two engines can develop about 600 horse-power. The building itself is a plain red brick structure, tastefully finished, and the foundations rest on a solid ledge of rock. The smoke stack, 100 feet high, lends quite an ornamental feature to the structure.

The engine and dynamo room, shown in plan and elevation in Figs. 1 and 2, is 48 feet by 52 feet, having a truss roof, with monitor ventilator, and is neatly finished with varnished pine, the floor being of one-inch kiln-dried birch, resting on a four-inch matched spruce flooring. In this room are two McIntosh and Seymour compound condensing engines, each of 300 horse-power capacity when supplied with steam at a pressure of 125 pounds. These engines are so placed that the crank shafts are in the centre of the room, the cylinders being towards the boiler room. The two engines, one on each side of the room, are also in line and are coupled direct to a "jack" shaft, no countershaft being used; this shaft can be run by either engine, or both engines, by means of friction clutches. The engines and the bearings of the jack shaft rest on one solid foundation. Each engine is provided with two driving pulleys, the outside pulley of each being provided with a governor, and the inside pulley having the Eclipse friction clutch. The



Figs. 1, 2 and 3.—Electric Light Station, Natick, Mass.

jack shaft is 6 inches in diameter, and carries on it four sets of tight and loose pulleys 96 inches in diameter, making 200 revolutions per minute, and giving a belt speed of 5,000 feet per minute.

The shafting and pulleys were furnished by the Holyoke Machine Company, of Worcester, Mass., who are making a specialty of this class of work, and the action of the loose pulley is particularly worthy of notice. These loose pulleys do not run in the usual manner on the shaft, but are supported by a separate bearing resting on the foundation, which has a hollow base, through which the shaft passes, and which is turned on the outside to fit the loose pulley. The pulley, therefore, does not rest on the shaft at all, and never revolves except when a dynamo is being shut down or started up, thus doing away with a large amount of useless friction and wear and tear of the pulley and shafting.

The dynamos can be placed on both sides of the jack shaft, but at present all the dynamos are being driven on the side farthest from the boilers. These consist of two 50 light Thomson-Houston arc machines, one 1300 light Thomson-Houston alternating incandescent machine, and one 80 horse-power Thomson-Houston generator for power circuits and electric railway service, should the company be granted the franchise for which they have applied. The dynamos are driven by Schieren belts, and are situated 15 and 21 feet respectively from the centre of shaft.

The switch board is of the skeleton type, and is made of varnished pine, set out so far from the wall that a man can work behind. The wires are all on porcelain knobs, and the wires from the dynamos are all conducted under the floor on porcelain knobs, being brought up through the floors through glass insulators, so that there are no wires whatever in the dynamo room, except on the switch-board and for the lamps in use in the room. In the centre of the switch-board next the floor are the arc machine controllers, surmounted by the new type of arc light switch-board set in slate. On top are the arc circuit lightning arresters. On the left of the switch-board are placed the power circuit switches and arresters, and on the right the alternating current switches, meters, and lightning arresters. The whole gives a very neat and tasteful effect, very pleasing to the eye, as well as conforming with all the requirements for protection from fire. The board is wired for three 1300 light alternators, with four circuits, and is so arranged that any dynamo can be put on any circuit, or any dynamo supply all four circuits when running light.

In the cellar among the foundations are situated two Lighthall surface condensers and heater combined, made by the South Brooklyn Steam Engine Works, South Brooklyn, N. Y., and two Knowles air and circulating pumps, each engine having a set for its own use. These condensers are controlled by a vertical shaft and hand wheel on the engine-room floor. In addition, there is a National feed-water heater, which is heated by the exhaust steam from the boiler feed, air, and circulating pumps.

The foundations are made of solid granite about three feet high, resting on solid rock, and surmounted by about four feet of brick work. Brick piers support the 6 x 12 in. beams for the floor.

In the boiler-room, shown in Figs. 1 and 3, are two 125 horse-power boilers made by the Cunningham Iron Works, of South Boston, and there are foundations for two more. They are designed to work at 125 lbs. of steam, and are fitted with the famous Jarvis setting. A Spencer damper regulator is also provided, and a Pratt and Cady steam trap, for returning all the condensed steam to the boilers. Two five-inch steam pipes convey the steam to the engines.

The smoke stack has granite foundations resting also on the rock, and is 100 feet high, and 11 feet square at the base, with a round flue 60 feet high. A curious feature about the smokestack is that it has not settled one hairsbreadth since its erection, owing to the rock foundation. The feed-water is taken from a stone reservoir which has been built about 150 yards away from the station, and which is 20x34 feet, by 22 feet deep. The discharge flows into a brook in the vicinity.

The station is conveniently situated on the Saxonville branch line of the Boston & Albany R. R., which commences at Natick, and on the railroad side there is a coal shed capable of holding 350 tons of coal.

The station was designed by the engineering department of the Thomson-Houston Electric Company, under the able supervision of Mr. H. C. Patterson; and Mr. Fone, the treasurer and superintendent of the Natick Electric Company, may justly feel proud of one of the neatest and most compact stations of it size in the country.

It is worthy of notice that the Natick Electric Company have just purchased a controlling interest in the Natick Gas Light Company, and will thus be secure from competion tending to the reduction of legitimate profits.

THE INFLUENCE OF ELECTRIC RAILROADS UPON TRANSATLANTIC TELEGRAPHY.

BY CHARLES CUTTRISS, ELECTRICIAN COMMERCIAL CABLE CO.

It would hardly seem possible that the two above mentioned industries could in any way clash, but the following account of trouble traced directly to an electric railroad will show that they do so, and that ultimately difficulties may arise which will have a serious effect upon transatlantic telegraphy, and unless some remedy is found, we may possibly have to resort to a less speedy communication between the two countries.

For many years it was the practice of cable companies to pick out some quiet, secluded spot in which to land their cables and to use land lines for the remaining distance to the nearest important city, using it as a radiating centre. This plan necessitated one transmission or repetition more than was actually necessary, and also caused a loss of time which it was very desirable to save. The Commercial Cable Company was the first to make an innovation, and in order to give quicker communication decided to land their sea cable at Coney Island, and continue it with an underground cable through Ocean Avenue and Brooklyn into the heart of this city, thereby practically making the terminus of their cable in Wall street. Past experience had shown the advisability of using a return earth circuit as far as the sea, so the underground cable was constructed with four cores laid up in the usual manner and only separated from one another by about $\frac{1}{32}$ of an inch.

The cable proper is connected to one of the cores by a permanent sea joint, and the diametrically opposite core, which is used as the return earth to the sea, is soldered directly to the sheathing wires of the sea cable, and the other two cores are kept spare in case of trouble.

This plan has given the utmost satisfaction until within the last few months, when we began to experience some trouble from occasional kicks on our receiving instrument; sometimes they would be so strong as to obliterate a signal. As these kicks are nothing unusual during the summer months, owing to thunder storms and other atmospheric disturbances, they were for some weeks attributed to such causes.

During this period it was also noticed, when testing the cable, that the mirror seemed to be very unsteady, and had erratic movements, which denoted by their abruptness that the cause of disturbance was near this end of the cable and was such as might be produced by a small fault.

To satisfy myself on this point I had the cores cut at the cable house on Coney Island, and while I was testing the undergrounds, the electrician at Canso, Nova Scotia (the distant end of the cable), was also testing the sea cable. The results showed that both the undergrounds and the cable were in perfect condition, but it was observed on the undergrounds that there was some disturbing cause in their neighborhood; as, after perfectly discharging the cores, they would in a few seconds become quite heavily

charged, always with the same potential; this phenomonon of course was only remarkable in the degree of charge. So far, we had arrived at only negative results, as the kicks, etc., were still present on joining up the working instrument.

About this time it came to my knowledge that there had recently been an electric railroad established, running from Prospect Park, Brooklyn, to Coney Island by way of the old Coney Island horse car road. Immediately it occurred to me that here possibly was the source of trouble. It must be remembered that ocean cables are operated by a recording instrument, that is so sensitive that a current of $\frac{1}{1000}$ of a milliampere will produce a distinct working signal; hence it is quite conceivable that, although the electric road does not in any part of its route approach our underground cables nearer than about *half a mile*, disturbances might be produced by the ever-varying power used in starting and running the cars. To prove the correctness of the assumption, I connected a telephone between the cable and its return earth and could distinctly hear the starting and stopping of the cars. The telephone was then connected to the cable and a local earth in the city, namely, the water pipes; the sounds then became so much louder that they could be heard with the telephone a short distance from the car. The testing galvanometer, a Thomson astatic, of course could not pick up such rapid vibrations, but it shows deflections and kicks to such a degree that we have sometimes been obliged to give up testing and try at a more favorable time, such as 1 or 2 a. m. when the cars have stopped for the night. This naturally is somewhat inconvenient.

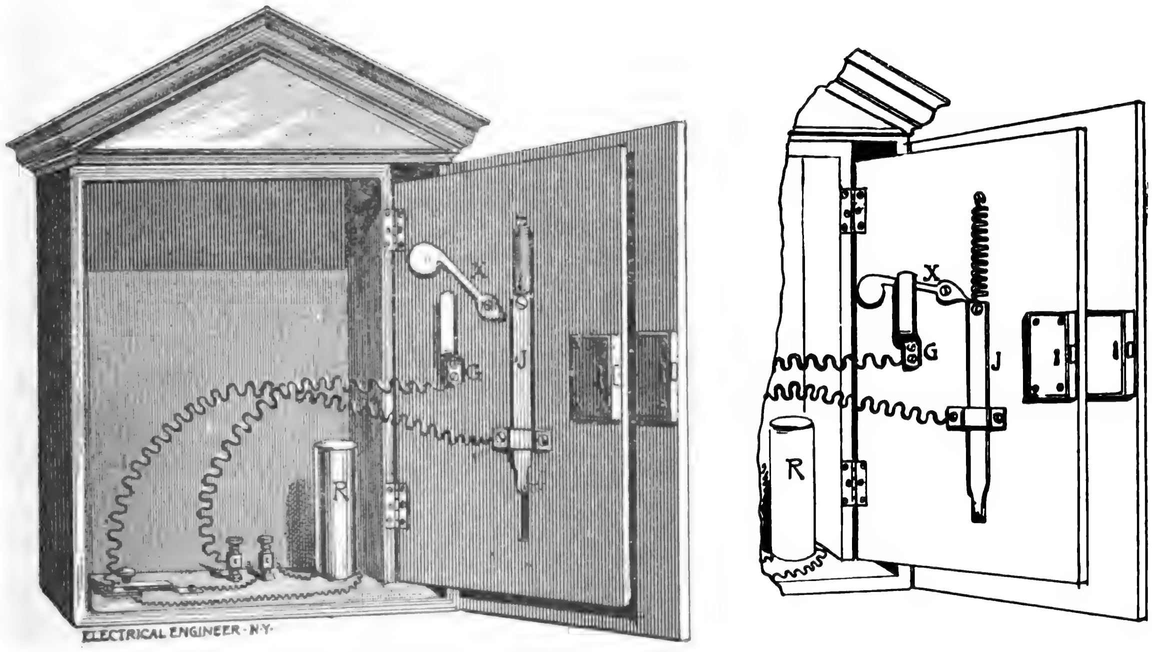
Now comes the question, if the disturbance is so severe with the railroad at a distance of half a mile or 2,640 feet, what would be the effect on the company's property if at some time an electric road should be projected down Ocean avenue where the rails would in all probability be within 4 or 5 feet of the cable for a minimum distance of 5½ miles? With telephones and ordinary telegraph instruments the use of a metallic circuit is a good protection, but in the present case it is proved that a metallic circuit through the disturbed district does not grant immunity from serious disturbance.

One point is still to be determined in regard to this phenomenon, namely, to ascertain for a certainty whether the effects produced are to be attributed to conduction through the earth and water to our armoring, or if it is an inductive effect. The fact nevertheless remains, that if electric roads should be greatly augmented in our immediate vicinity the disturbances on our lines will be seriously increased, and at present it is difficult to conceive of any remedy other than the adoption by the roads of a double trolley system.

The tests show our undergrounds to have a dielectric resistance of about 350 megohms per mile, so the idea of any leakage cannot be entertained.

ROBBINS' BURGLAR AND FIRE ALARM SYSTEM.

The various central station systems for electric protection which have been devised have either required electro-mechanical action for producing an individual signal over a connecting wire in combination with other similar alarms, or else have depended upon a variation of current through an independent connecting wire to produce an alarm. Frequently long periods of idleness, rust or dampness render the mechanical arrangement inactive when required, and simultaneous operation of two or more alarms produces conflicting and unintelligible signals. The latter method, whereby an alarm is sounded by any change in the current passing from the central office through the point protected, is, therefore, the most reliable one.



Figs. 2 and 3.—Robbins' Burglar and Fire Alarm System.

Such systems have been in successful operation for several years past, but as they indicate only a disturbance of the circuit, without rendering a specific alarm, it has been necessary to provide an independent circuit for each alarm. This is expensive, and, in instances of wire wrecks, serious complications necessarily follow, to the detriment of efficient service. In some cases a burglar alarm and district telegraph company is obliged to maintain several alarm wires for one building, in addition to their regular watchman's signal or messenger call circuit.

To obviate this difficulty a system has recently been devised and patented by Mr. A. C. Robbins, of Brooklyn, N. Y., which, while depending entirely upon variation of current for producing an alarm, locates the alarm by the quantity of variation produced, and admits of several independent alarms being worked on one central office circuit without interference, together with the usual electro-mechanical watchman's signal and messenger call apparatus. The style of alarm is immaterial, provided that it admits of a certain quantity of current being

passed through it to earth, and of different quantity to that passed by any other alarm in the same circuit. At the central office is arranged an exact fac simile of the protective circuit in its normal condition, and this miniature circuit is provided with means for readily placing it in the same condition as is the protective circuit when an alarm is sounded.

Current from a main line battery passing through the opposing coils of a differential galvanometer divides between the alarm and miniature circuits, and, both being equal, the galvanometer is unaffected, and its needle remains at zero. Any change in the quantity of current passing in the alarm circuit, however, causes a deflection in the galvanometer, which closes a local circuit, and sounds an alarm. When the fac simile circuit has been placed in like condition, the galvanometer returns to zero and the alarm ceases; a glance at the fac simile will then reveal the source of alarm, and the apparatus is then ready to receive a second alarm.

Should two or more alarms be sounded together, they are simultaneously located.

Fig. 1 is a diagram of the system, showing various combinations of alarms and mechanical apparatus. A and F are mechanical signal boxes; B, E and G represent burglar alarm resistances; C is a thermostatic, and D a municipal or street fire alarm. At the central station, M B represents the main battery; J the differential galvano-

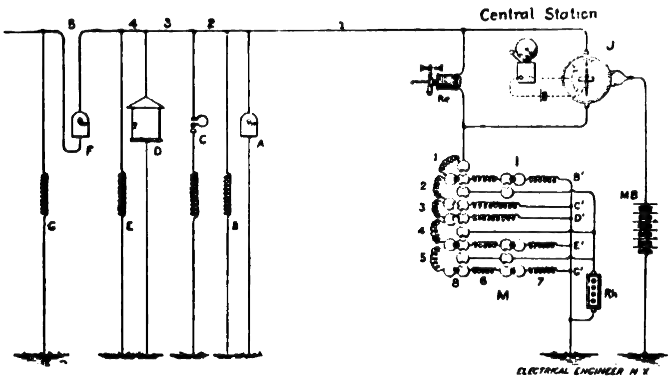


FIG. 1.—ROBBINS' BURGLAR AND FIRE ALARM SYSTEM.

meter; M being a fac simile of the external circuit in which B′, C′, D′, E′, and G′ are resistances made exactly equal to those represented by B, C, D, E, and G, and R*h* an ordinary neutral relay placed in the bridge for the reception of mechanical signals.

Now should the box A be sprung, making direct earth connection, a given number of times, the difference of potential created between the two circuits causes current to pass through the relay R*h* a corresponding number of times, and to record the signal. The box F is of the variety which opens the circuit to send the signal, and upon being sprung interrupts the circuit to points beyond F, a given number of times, produces difference of potential, similarly to the former and actuates the relay at the central in the same way.

If an alarm is sounded, and the circuits are equalized by breaking the connection at 8, in circuit G′ of the fac simile, it is evident that the branch circuit of alarm G is interrupted. Should connection with G′, at 9, produce the desired result, it will indicate that the alarm resistance of G has been shunted. If the result is obtained by connection at 10 it shows that the entire branch G has been shunted by an earth connection of no resistance.

It is impossible to produce a short circuit by an earth connection at *any* point in the circuit, as the resistances of the different sections of the protective connecting wire 1, 2, 3, 4 and 5 are compensated for by resistances at the corresponding figures at M; and the branches are likewise protected, the branch wire containing resistance in proportion to that of its alarm. Thus, the resistance of branch G, being 500 ohms, 50 ohms, or one-tenth part, are contained in the branch wire, and the remaining 450 ohms are placed as the alarm resistance. In the fac simile of branch G′, the branch wire resistance is represented at 6, and that of its alarm at 7.

Should the thermostat of branch C become heated, it closes circuit to earth, and the connection of C′ locates the trouble; likewise, the sounding of an alarm from a street box of branch D completes a similar connection to earth, and is located by connecting D′. The rheostat R*h*, in the central office, is used in locating shunts containing more or less resistance.

In locating alarms, five rapid operations, at most, may be necessary before an alarm can be located, as follows: 1, connecting for fire alarms; 2, opening of burglar alarms; 3, shunting of burglar alarms; 4, shunting of burglar alarms, and insertion of resistance; 5, locating two or more simultaneous alarms, this latter operation being a combination of the previous ones. Usually, one of the first three operations is sufficient. In practice it is desirable to replace the fac simile shown, with apparatus so arranged as to require little or no electrical skill on the part of the operator.

Municipal fire alarm telegraphs have heretofore been somewhat expensive to construct and maintain, a reliable and non-interfering mechanical signal box system costing too much for the resources of the smaller cities.

The street fire alarm box used in the Robbins system is shown in Figs. 2 and 3, and consists of the ordinary box, or casing, provided with a suitable lock for which keys are supplied to responsible people who desire them, and a second, or inner compartment, containing the apparatus, and to which access can be had only by officials possessing special keys.

The apparatus consists of a coil of resistance wire R; a special signal key K′; a rod J, moving in guide ways, and from the lower end of which a hook or pin projects outwards through a slot in the inner door; a lever X, and a contact stop G.

To signal an alarm of fire the citizen unlocks the outer door of the box, and by means of the projecting hook pulls the rod, J, downwards, allowing the lever, X, by its own weight to fall past and make connection with the stop, G, as shown in Fig. 3. The rod, J, is then retracted against lever, X, holding it securely in position. This operation completes a circuit through the coil, R, rod, J, lever, X, and contact, G, to earth.

At the central, or department headquarters, to locate the alarm, it is only necessary to turn a dial contact switch in the fac simile until it is brought in contact with the resistance corresponding to that of R in the box from which the signal emanates. If further signals are required the official in charge makes use of the key, K′, each depression of which shunts the coil, R, and produces a stroke upon a bell operated by relay R*h* at the central office.

At the conclusion of service, the official releases rod, J, by lifting lever, X, leaving the apparatus in position for future use, and necessitating removal of the contact in the fac simile, which may be understood as a signal that the fire has been extinguished.

The absence of complicated mechanism, and the extreme simplicity of this box, should admit of its being utilized even in large villages, where it is now customary to sound an alarm from the nearest church or other tower bell. The alarms being connected in multiple, the destruction of part of the branches, or of a section of the connecting wire, will not prevent the operation of such of the alarms as remain connected.

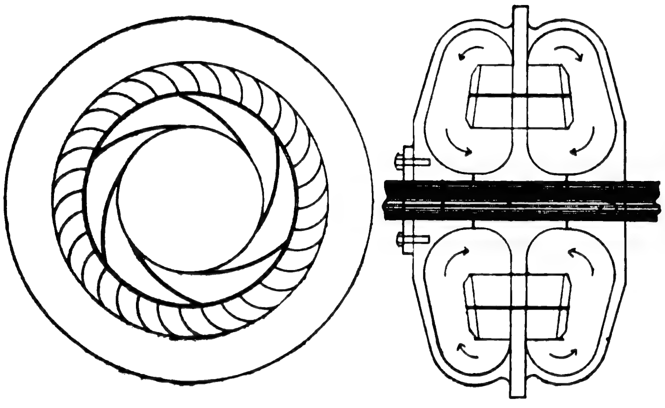
THE CHICAGO ILLUMINATING COMPANY, recently incorporated with a capital stock of $500,000, have purchased several local South Side plants in Chicago, and will continue to furnish, with increased facilities, arc lights and current for power purposes to consumers.

THE TURBINE AS AN INTERMEDIATE ELECTRIC CAR GEAR.

BY E. S. PILLSBURY.

SINCE the earliest experiments in electric traction much time has been devoted to the development of a satisfactory power transmitting device for coupling the electric motor to the car axle.

Many different methods have been tried, but at present spur gearing appears to hold the field against all competitors. Nevertheless it has many serious faults. Among the worst are the unavoidable noise and wear which occur most between the high speed armature pinion and its gear,



FIGS. 1 AND 2.—A LIQUID CAR GEAR.

and the impossibility of obtaining a variable speed ratio between the armature shaft and the car axle.

To illustrate the evils of this latter more fully, let us note the conditions that must be filled by a motor in traction work. It requires from three to five times as much pull to start a car as is required to drive it ten miles per hour. Motor builders find that in a well designed motor the torque or pull which it is capable of exerting is almost directly proportional to the current in the armature and entirely independent of the speed of the armature. From which it follows that a motor geared to a car axle and designed to develop 15 h. p. when the car is moving 15 miles per hour, is capable of developing, without overloading, just 1 h. p. when the car is moving one mile per hour and 5 h. p. when the car is moving five miles per hour. In other words, the energy available on the car axle is proportional to the car speed, while the energy taken from circuit is proportional to the traction. Thus we have the apparent anomaly that when the motor is doing the least work it takes the most current, and just before it gets ready to do work it takes from three to five times as much current as it takes when doing its maximum work on a level grade.

The above statements are made on the supposition that the field is saturated, which condition, though not always strictly fulfilled in railway work, would not materially influence the above conclusion.

However, the writer does not deem this question of efficiency so very important in practice, but this excessive starting and "coming up" current does give much trouble on small roads, where it is sometimes necessary to keep moving three times as many generators as would be required were the power used constant at its average; and even on large roads when a block occurs, as was witnessed recently, where a line of cars half a mile long all tried to start at once.

The writer wishes to draw attention to a starting and climbing device, more especially applicable to locomotives and appliances, where power is used in large units, but which may be applied to a single motor truck, and by which he believes many of the disadvantages above shown can be avoided.

Figs. 1 and 2 show diagramatically a case enclosing a turbine wheel designed to be driven direct from a motor, that is, a so-called centrifugal pump. Surrounding this, and supported by the case, is another series of turbine blades the case forming a suitable passage for the return of the liquid to the centre of the pump. Thus we have through the pump, the turbine, and returning by the passages inside the case, a complete liquid circuit, and if we drive the pump at any constant speed we shall get a speed from the turbine, varying according to the pull it is compelled to exert.

Turbines do most work and do it most efficiently at about 55 per cent. of their free speed, but between 25 per cent. and 75 per cent. of their free speed will give a very large percentage of their maximum output. As the pump is simply an inverted turbine it will follow the same laws, and hence will place in the liquid nearly the maximum amount of energy of which it is capable, while the velocity of flow through it varies from one-quarter to three-quarters of the velocity when there is no back pressure. Now it will be seen that if the pump forces into the liquid nearly the same amount of energy while the velocity of flow through it varies in the ratio of one to three, and if, when supplied with any given velocity of flow, the turbine is capable of developing nearly the same amount of energy while its speed varies in the ratio of one to three, then we may expect from the combination, the speed being constant at the pump, that the speed of the turbine can vary in the ratio of one to nine, the pull being somewhere nearly in inverse ratio.

In regard to the output for a given size of machine we can only say that high speed turbines are very powerful in proportion to their size, a 15-inch wheel of modern design being rated at about 350 h. p., running at from 600 to 700 revolutions per minute.

In Fig. 3, attached to the starting device, is shown an electrically actuated friction clutch, *a a'*, by which, when the car has attained any given speed, the driving and driven turbines will be automatically coupled together and the car driven direct from the motor through a bevel pinion and a pair of bevel gears. Two clutches, D and E, which may be actuated either electrically or mechanically, are shown for coupling the axle to the bevel gears, thus driving the axle in either direction without reversing the motion.

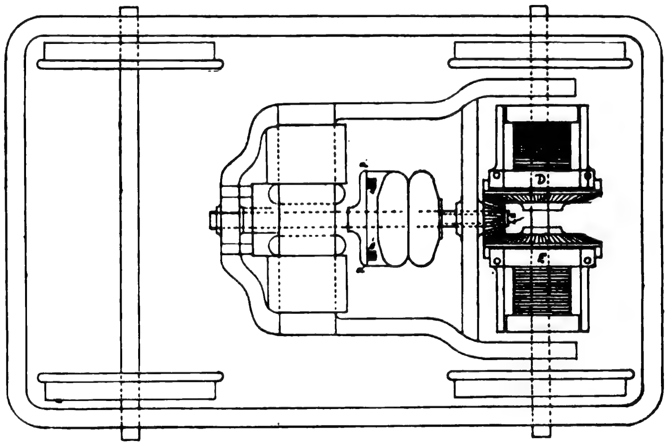


FIG. 3.—A LIQUID CAR GEAR.

With this method of transmission the car may be controlled entirely by one switch, and if reversed while running at full speed the motor will not be overtaxed; in fact, the car might be entirely controlled by the clutches on the axle.

Though it is not considered necessary to claim for this starting device a high efficiency, yet it is believed that if laid out so as to introduce those features which have rendered the modern turbine among the most efficient of prime movers, and considering the fact that we are here enabled to escape the most serious loss of the turbine, namely,

energy retained by the water on leaving the wheel, as well as the fact that a liquid introducing less friction than water may be used, we may find it a very efficient means of continuous transmission for certain kinds of work.

THE RIVER AND RAIL ELECTRIC STORAGE CAR SYSTEM.

There has now gone into operation on the dummy road in South Brooklyn the electric storage car of the River and Rail Electric Light Co., of this city, which claims attention on account of the number of novel features involved in its operation and construction, constituting a marked departure from the usual practice.

Before entering into a description of the car itself, it may be well to take up first the element from which the power is derived, namely, the storage battery. This, as every other detail in the system, is due to Professor Wm. Main, who has been for a long time engaged in its development. The battery itself is what is known as a zinc-lead storage battery. Our readers will remember that early in the art M. Reynier experimented with this type of cell, using the zincs as the negative plates, but the results which he obtained were not sufficiently encouraging to warrant the general adoption of this type. The results of Prof.

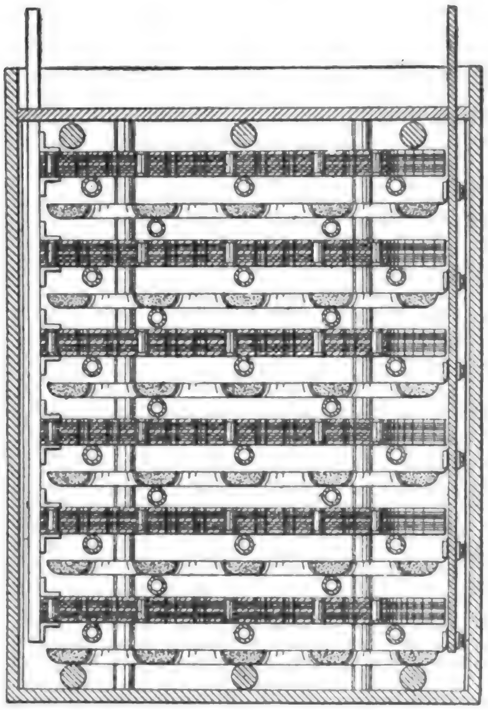

Fig. 1.—The Main Storage Battery.

Main's experiments in this direction, however, soon convinced him that the difficulties encountered by M. Reynier were attributable mainly to the fact that his plates were disposed vertically in the solution. The result of this arrangement was that the zinc plates, on account of the difference in density of the solution at various points, were unequally acted upon, and indeed frequently cut away. This phenomenon is also noticed in primary batteries in which zinc is employed, and in which the part at the bottom of the cell is usually eaten away considerably faster than that at the top. The natural remedy for this defect was recognized by Prof. Main and applied by placing the plates in a horizontal position, so that, notwithstanding differences in density of the solution, each separate plate would be surrounded by a layer of solution having the same specific gravity throughout.

The arrangement adopted is illustrated in Figs. 1 and 2, which represent the cell in vertical and horizontal section respectively. The positive or peroxide plate, it will be seen, consists of two outer sheets of lead, between which is placed a layer of sheets of thin lead foil. The plate is perforated, as shown in Fig 3, and riveted together at numerous points. This plate, when placed in the battery and worked for a short time, is acted upon so as to convert the lead foil into peroxide, which is firmly held in place. The negative plate, which is shown in Figs. 1 and 2, consists of a copper tray perforated and into which amalgamated zinc is poured so as to completely fill the tray, as shown in Fig.

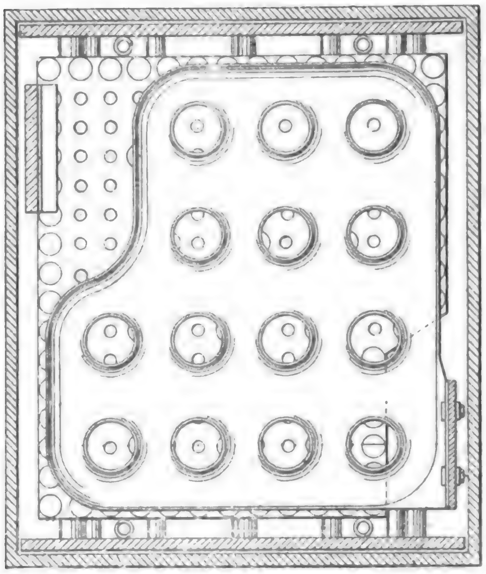

Fig. 2. The Main Storage Battery.

1. A very small number of charges and discharges serve to convert the zinc amalgam into a highly porous and spongy mass, having a great property of absorbing hydrogen. The cell employed on the car has 14 plates and weighs 45 pounds, of which 27 pounds is the weight of the metal proper. It has a capacity of 250 ampere hours; 60 of these cells are employed on a car.

The action of the cell under charge and discharge is well shown in the curves, Figs. 4 and 5, which give the results

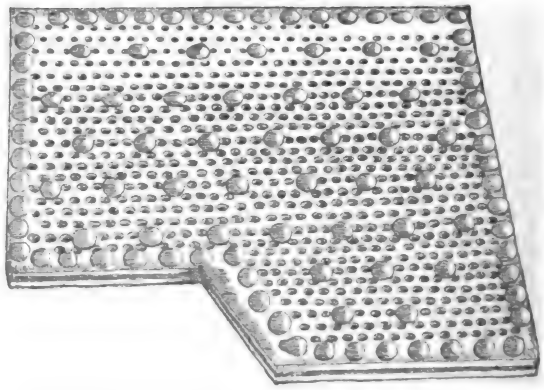

Fig. 3.—Positive Plate of the Main Battery.

of some recent tests and are sufficiently clear without further explanation.

Having described the battery, we may next take up the car itself. Our illustration, Fig. 6, shows the car complete as it stands on the track. Its distinguishing features are the rounded ends which furnish the space in which the motor man is placed so as to leave a clear passage for the entrance and exit of passengers. In this space are the controlling switch and lever and the brake placed conveniently for the manipulation of the motor.

The essential feature of every electric car, the electric motor and the gearing, deserves in this instance special consideration, as both these elements have been worked out by Prof. Main on entirely new lines from the practice here-

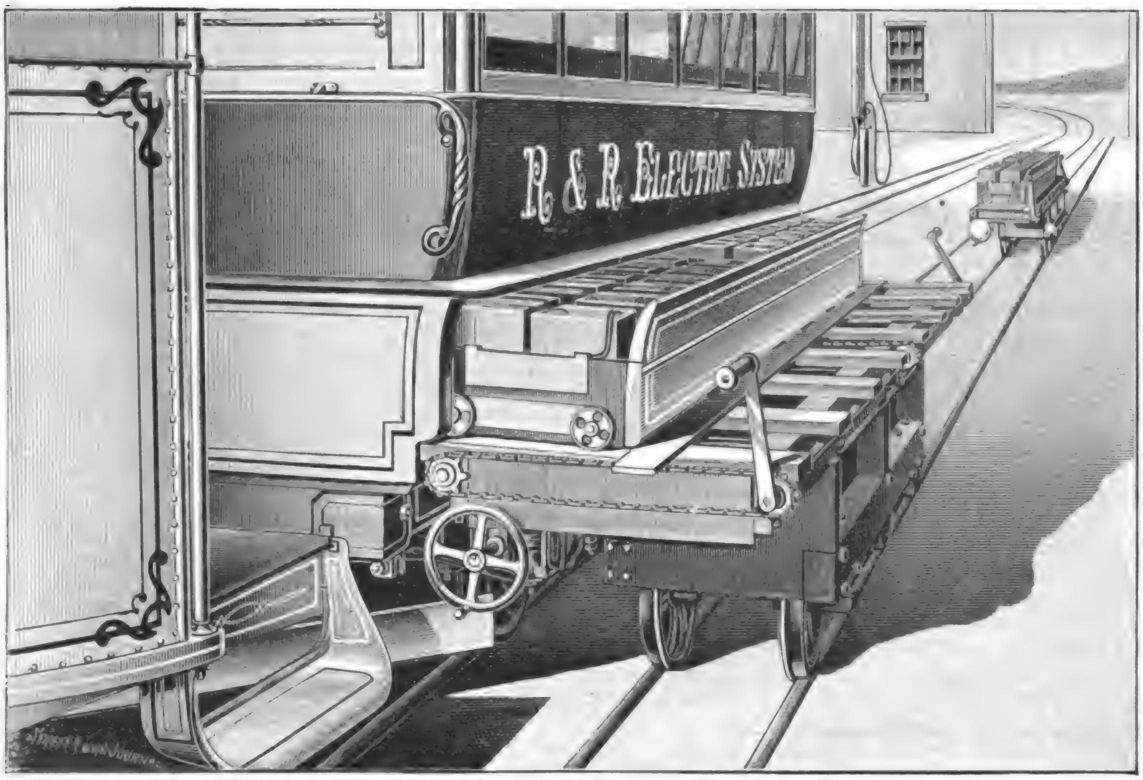

FIG. 10.—METHOD OF CHANGING BATTERIES, RIVER & RAIL SYSTEM.

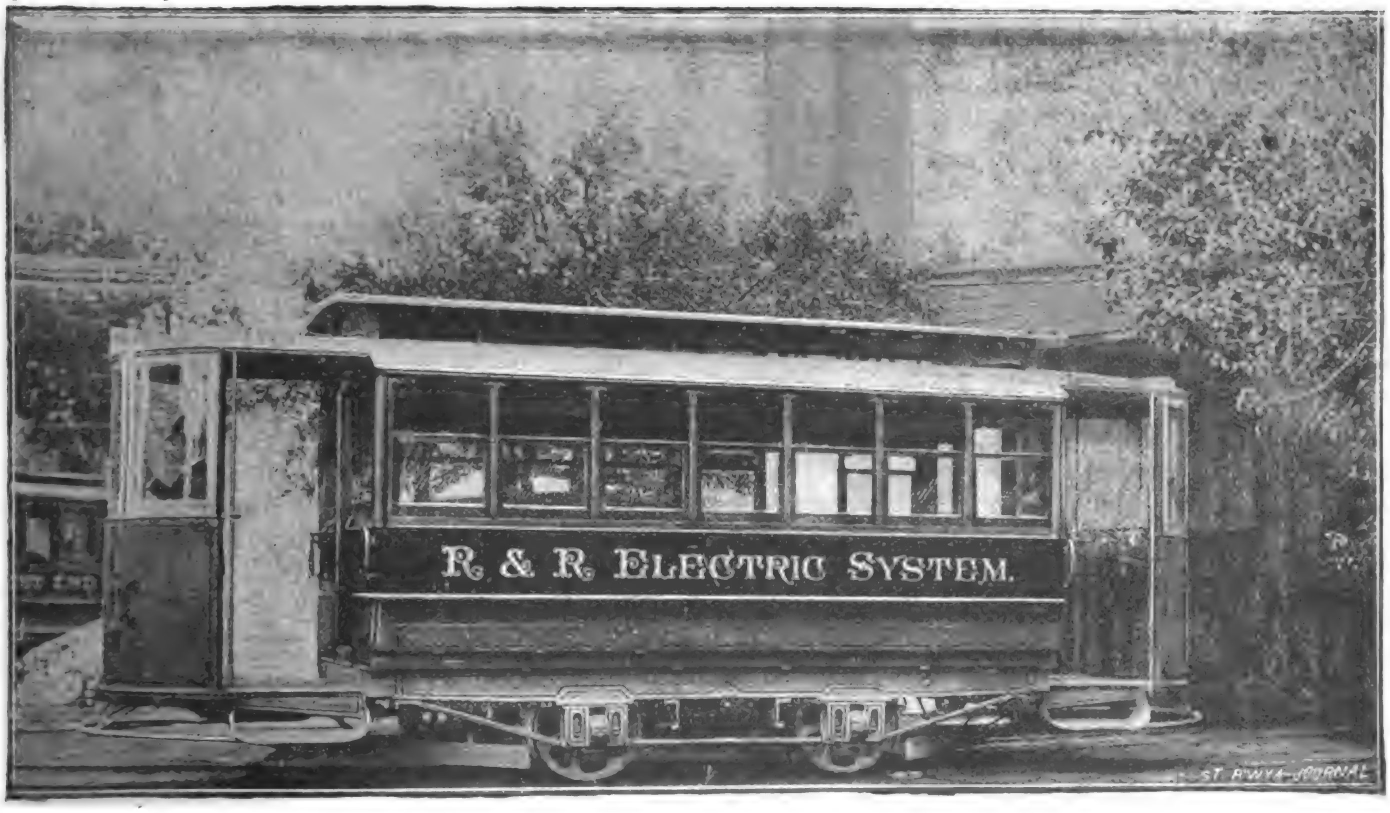

FIG. 6.—THE RIVER & RAIL ELECTRIC CO.'S NEW STORAGE BATTERY CAR.

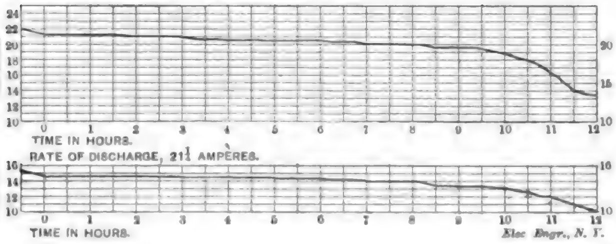
tofore in vogue. Prof. Main was among the first to recognize the fact that increased economy could be obtained by an arrangement in which the motor is kept revolving at a constant speed, and at which it operates at the greatest efficiency. At the same time he recognized the fact that an element of almost equal importance is the nature of the gear connecting the motor with the axle.

Taking up the motor first, Prof. Main was among the



FIGS. 4 AND 5.

first also to develop the design in which the armature is kept stationary and the field magnets revolve, and he has carried this still further in maintaining the wire on the field magnets also stationary, so that in reality there are no moving wires whatever on the motor. The latter is shown in perspective in Fig. 7. Prof. Main has adopted the multipolar type of machine with a particular arrangement, which is clearly shown in section in Fig. 8. Here, it will be seen, the armature A is held stationary by the casing and is surrounded on both sides by field magnets, one of which is shown at N N; opposite to this is a wood filling, the object of which will be explained presently. Placed at right-angles to the poles N N is a similar pair, having an opposite or south polarity. The filling shown opposite the poles N N is of wood, the object being to fill up the spaces between the two arms of each pair of magnets in order to avoid churning of the air and so as to give smooth working.

The core of the magnet D, it will be seen, is mounted directly upon the shaft of the armature and is surrounded by the magnetizing coils, which are placed in the cylindrical casing marked M M. This casing is stationary, as is also the magnetizing coil. The result of this construction is that both pair of poles of the magnetic system are influenced by a single magnetizing current, and hence are of a uniform strength, so that the action of each pole upon the armature is identical.

Another object secured by this construction is the shortening of the magnetic circuit. It will be understood from what has been said, that the lines of force emanating from both north poles, N N, for instance, pass into the armature A, travel through and along it for the distance of one-fourth of its circumference and then pass out to the other side into the south poles and back through the core to the other side again.

The armature is built up of specially rolled soft ribbon iron, wound spirally, the different convolutions being separated by insulating material; the ring is wound in Gramme fashion, with special connections on account of the employment of four poles. The commutator also remains fixed, the brushes alone revolving. The motor shown and employed on the car revolves at 800 revolutions per minute, which corresponds to a speed of 12 miles an hour for the car.

The motor is directly connected with the driving mechanism, which is shown in perspective in Fig. 9, and which constitutes a radical departure from the methods heretofore employed in electric car practice. As remarked above, the motor is kept in continual revolution, and hence some gear must be employed in which starting and stopping can be accomplished without shock. This has been accomplished by Prof. Main by the employment of a peculiar gear, which is based upon the sun and planet motion, with some essential modifications. The central shaft of this gear, which is directly connected to the motor, revolves at all times with the speed of the latter. Two portions of this shaft, however, are slightly eccentric and have loose pinions mounted upon them, which mesh at all times with the internally toothed gears which surround them. These pinions may revolve idly with the gears, or may drive them, according as they are allowed to gyrate with the eccentric and revolve, or to gyrate only, the pinions being connected by double gimble joints to discs concentric with the central shaft. Each disc will therefore revolve with its pinion when idle; but when arrested by the grip jaws, operated by means of the beveled gear wheels and shaft shown, they will cause the pinion to drive according to the direction in which the beveled gears are turned by the motor man; either one pinion or the other will drive, with the result that the car can be driven at two different speeds, slow and fast, notwithstanding the uniform speed of the driving motor. By releasing both grip jaws, neither pinion drives, and the car may be brought to a standstill with the motor revolving at full speed.

These operations of clutching are performed by the motor-man by means of a lever on the platform. The two internally toothed gears are connected permanently to each other and to the double sprocket which drives both chains, and action comes from either one or the other, or from neither, as the case may be. The driving sprocket wheels are connected to either axle so that both are driven direct. The whole mechanism is lubricated automatically from within by centrifugal action. The oil, as it drops down, is caught in a pan which encloses the whole under the car, and by means of a loose traveling ring returns to a reservoir and is used over and over again. The friction on the gimbal joints is exceedingly small, the motion of the rubbing surfaces being reduced to a small fraction of an inch, and as the internal gears mesh over a considerable part of their cir-

FIG. 7.—THE MAIN MULTIPOLAR CAR MOTOR.

cumference, and are in addition completely flooded with oil, as well as protected from dust, their life is also indefinite.

In order to avoid all shock on starting the car, the sprocket wheels attached to the axles are mounted on drums which contain springs so arranged as to keep the chains taut and to receive the first impulse in starting. The action of the spring is to allow a certain amount of relative motion between the two axles, thus avoiding the hard driving action experienced when both axles are geared to one motor. The tractive power is therefore utilized without rigidity, so that the mere momentum of the motor, after the current has been shut off, and with the car standing, is able to start it and to propel it some

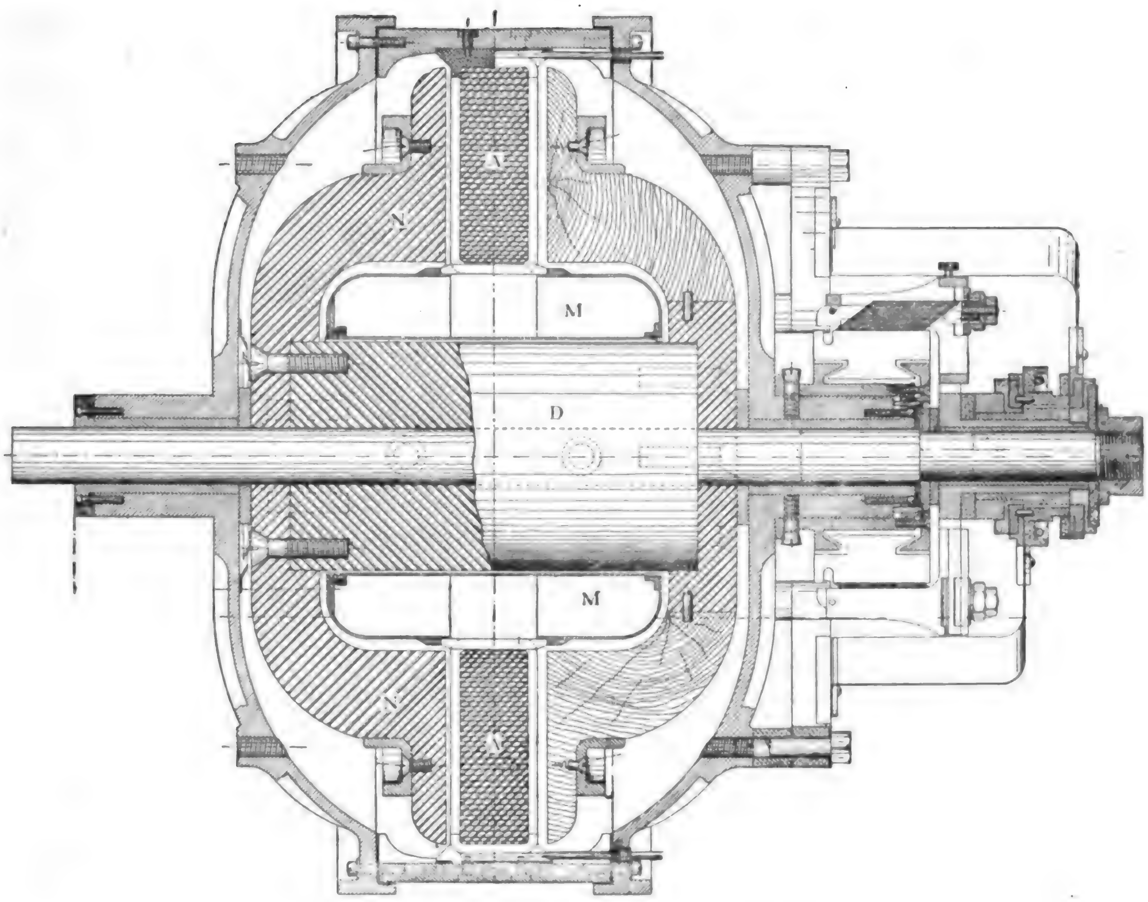


Fig. 8.—Section of Main Multipolar Motor.

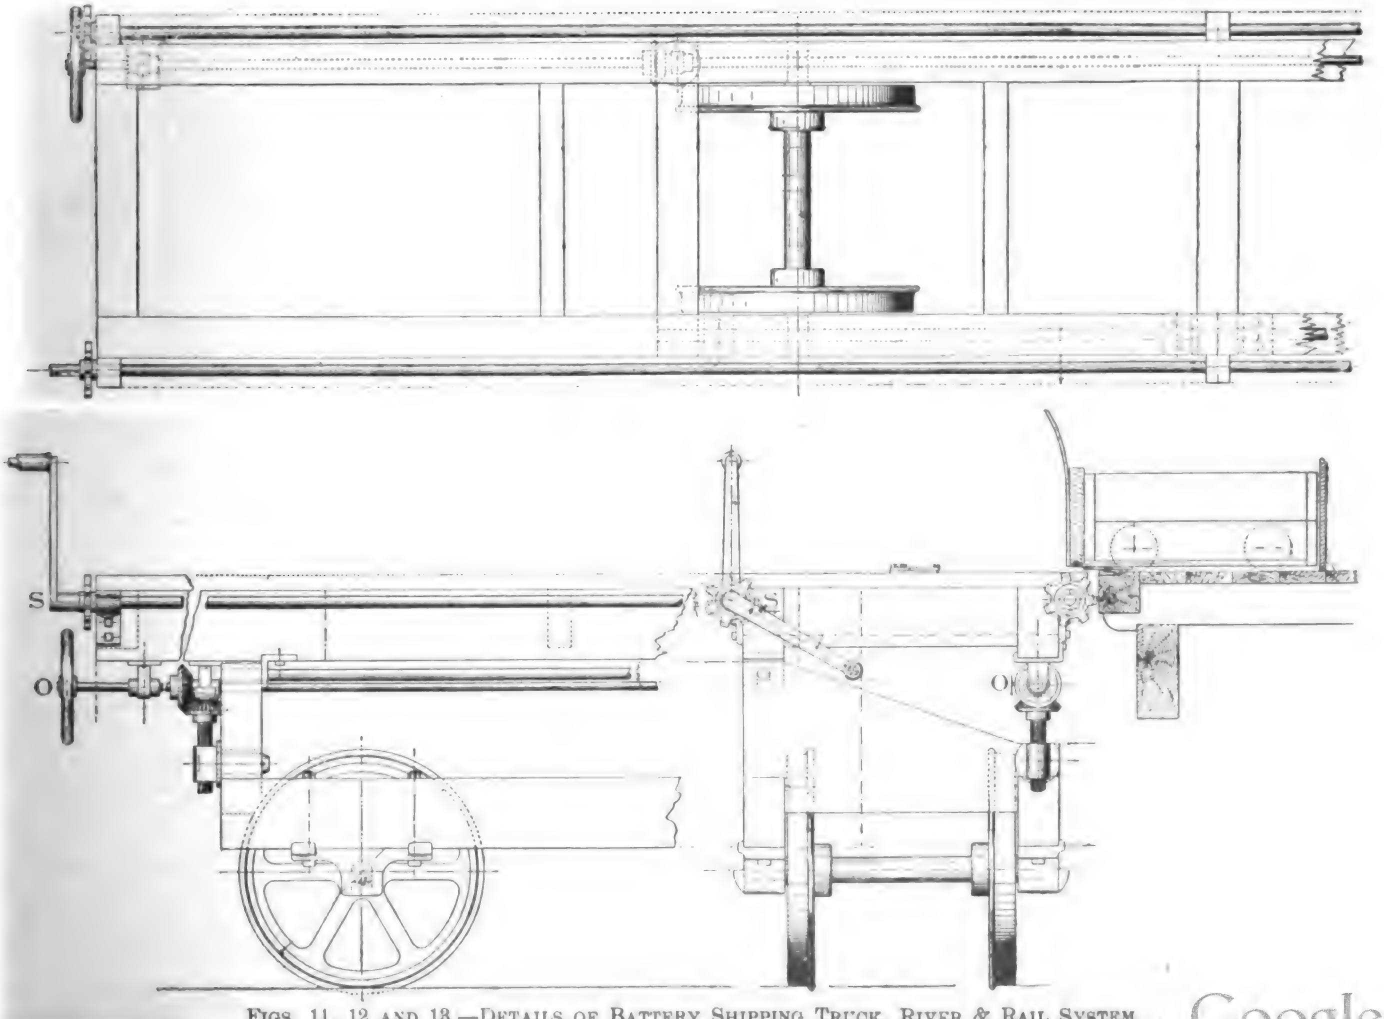

Figs. 11, 12 and 13.—Details of Battery Shipping Truck, River & Rail System.

distance. Provision has also been made for securing the pedestals of the car so that the wheel base can be slightly increased to take up any stretch in the sprocket chains which may occur.

These constitute the principal elements of the car, but it remains still to describe the method employed for taking out and replacing the discharged cells from the car. The arrangement employed for this purpose is illustrated in perspective in Fig. 10. Parallel with the track on each side of the car, as shown in the illustration, are narrow gauge tracks, on which a small platform car runs, the height of which may be regulated by means of the handle o, shown in detail in Figs. 11, 12 and 13. It will also be noticed that the battery cells are mounted in trays provided with wheels and fitted with latches to hold the cells in place. On top of the shifting table there is placed an iron bar extending along the entire length; the front of which, as shown in Fig. 13, has raised pieces so spaced as to come opposite the latches in the trays so that when the bar is brought up under them the latches are raised and the cells can be rolled out directly upon the platform. To remove the batteries at the same time these projections enter into engagement with shoulders on the latches and by means of the cranks, s s, shown in Fig. 13 and in perspective in Fig. 10, the entire series of cells can be drawn out at once. It will also be noticed that the cove panels of the car are removed with the cells, constituting, in fact, one side of the tray, a proceeding which is entirely permissible on account of the construction which is employed. The cells are immediately placed in circuit for recharging by flexible wires connected with copper bars above, which slide in slotted tubes, to the generator. Connection may thus be made with the cells at once and the cells wheeled off without any delay.

Prof. Main has devoted a large amount of attention to the working out of the details of this system, and the results already obtained with the car now in operation are of the most encouraging nature, and have attracted the general attention of street railway people, especially those engaged in work in towns and cities where the feeling against overhead wires is strong.

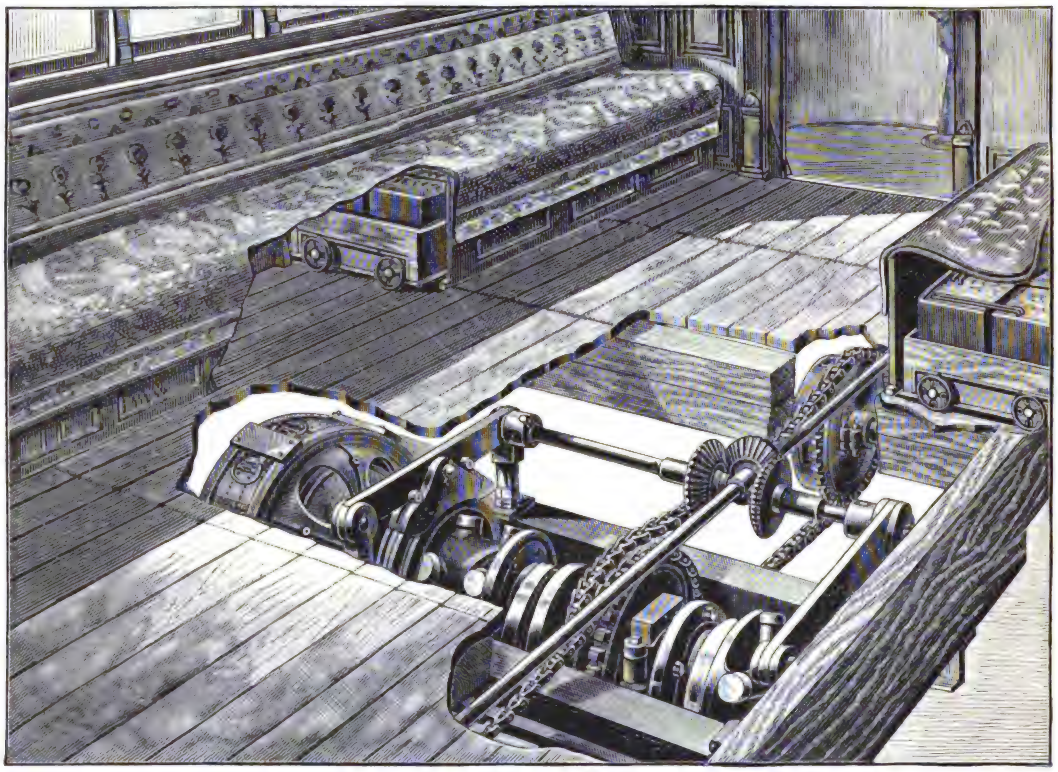

Fig. 9.—Driving Mechanism of the River & Rail Storage Car.

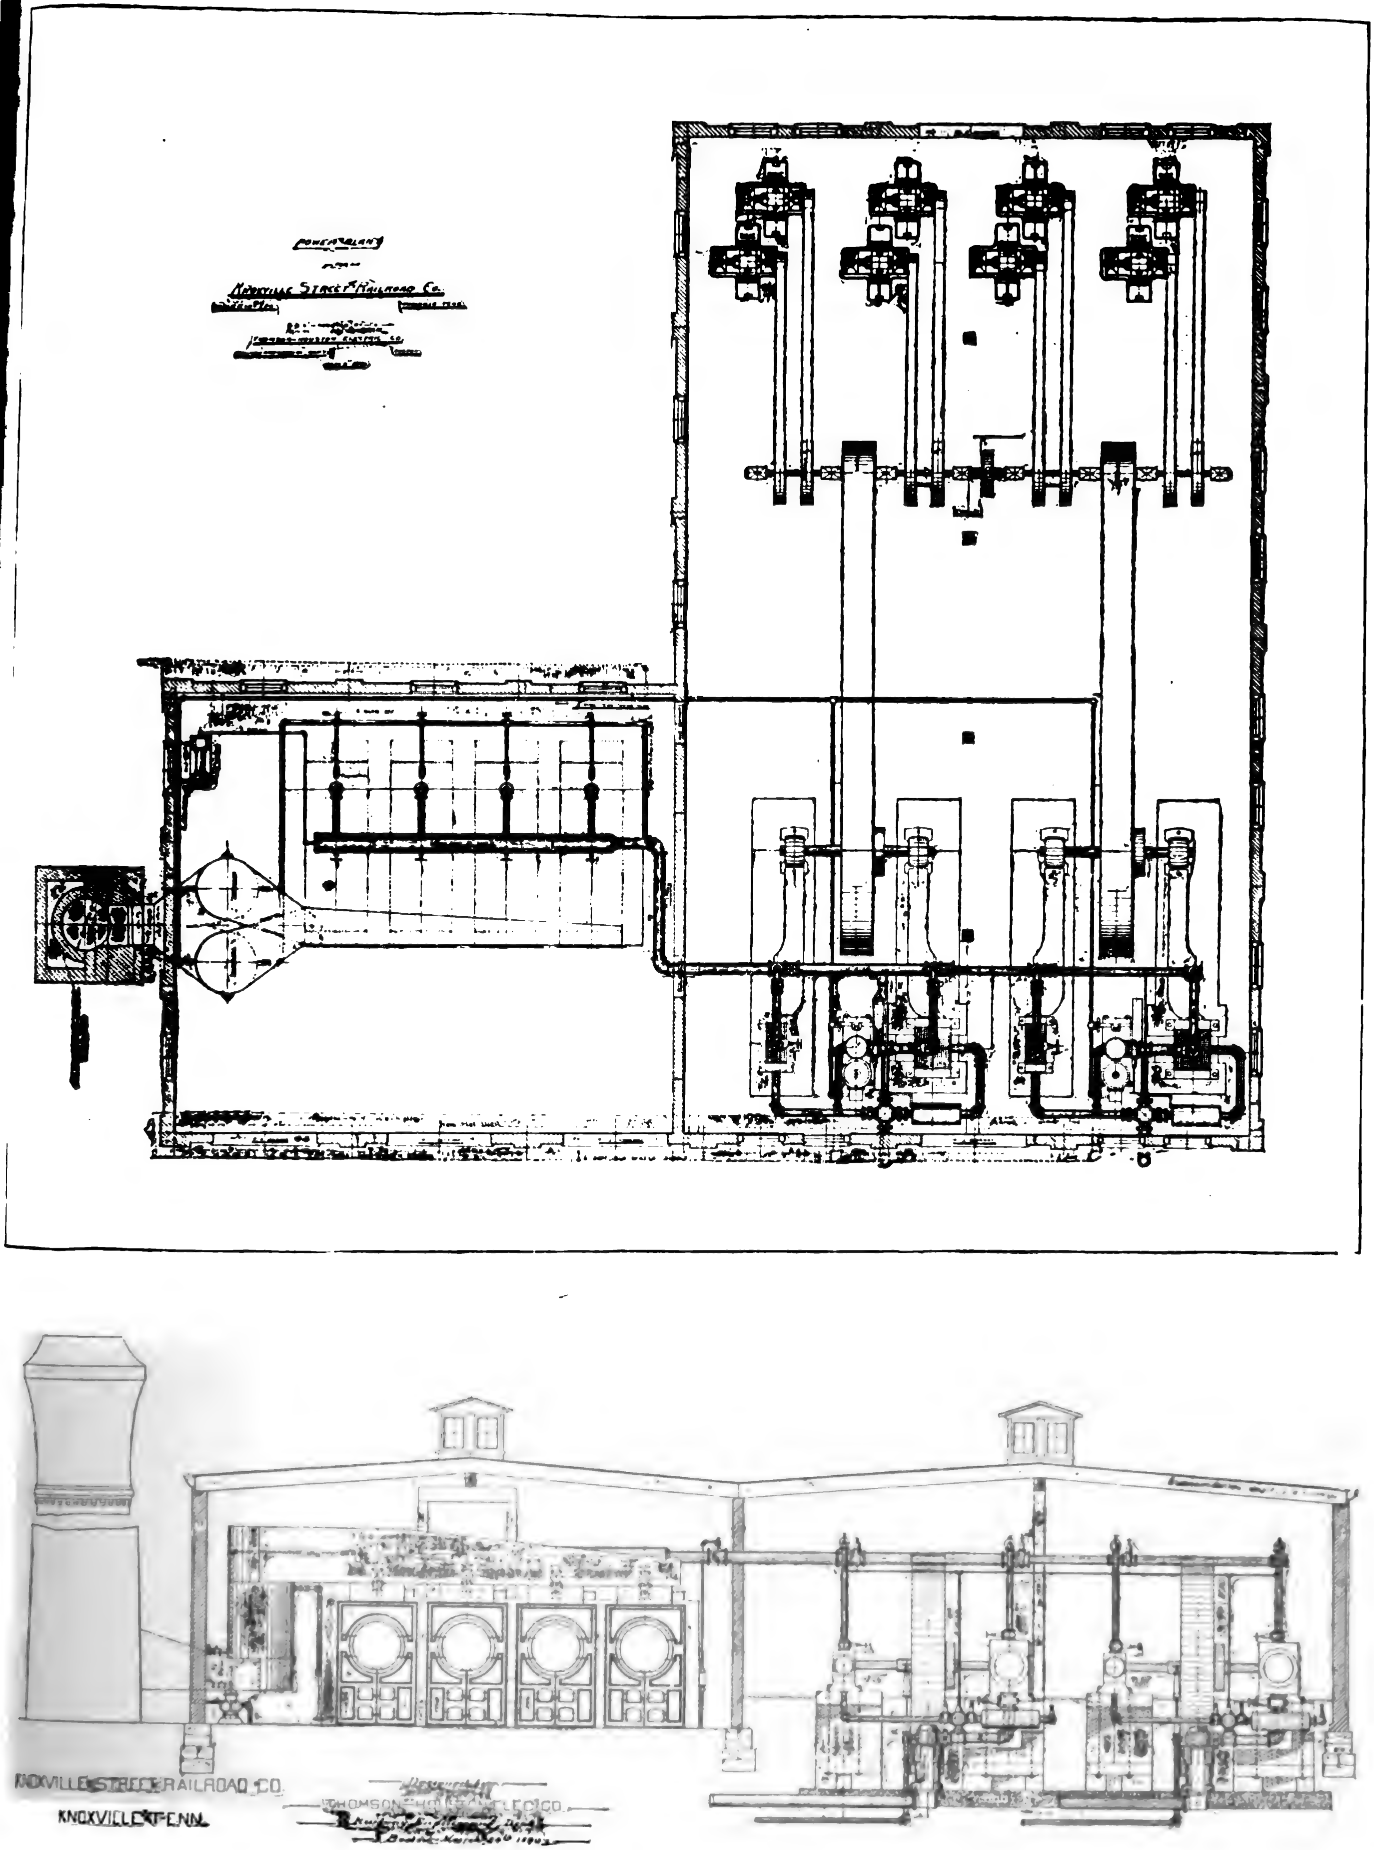
POWER STATION OF THE KNOXVILLE STREET RAILWAY CO.

One of the recent installations made by the Thomson-Houston Electric Co. is shown in the accompanying illustrations of the power station built for the Knoxville Street Railway Co., Knoxville, Tenn. The drawings, Figs. 1 and 2, are the plan and section, of the elevation, from which the construction of the station and the disposition of the apparatus can be readily seen. The building is one story, brick, and divided into boiler and engine and dynamo rooms. The steam plant consists of four steel tubular boilers built for high pressure to be operated at from 115 to 125 lbs. pressure, with furnaces designed for burning a low grade of slack coal. Economizers are also provided for utilizing the waste gases in bringing the feed water up to the boiling point before it is pumped into the boilers. Four ways of feeding the boilers are made use of and so arranged that in case of accident to any one of them, the operation of the steam apparatus would in no way be impaired.

The engines are of the cross-compound condensing Corliss type and so arranged that each pair, which is considered as one engine, can be operated as a twin engine, and in case of accident, either side can be run alone. Each side can also be worked high or low pressure, so that provision is made for operating the plant, even though half of the engine is undergoing repairs. This is the first plant of this kind in the world which has been erected for electric railway purposes, and very satisfactory results are anticipated from it. Each engine will carry its full load, under the varying conditions of railway work, on an evaporation of 18 lbs. of water per horse-power per hour. The engines are of extra large proportions throughout so as to withstand the severe service incidental to railway work.

The electric apparatus comprises eight Thomson-Houston railway generators, and the usual appliances for their operation. Each generator, as is the same with the engines, is arranged so as to be thrown in or out of action without interfering in the least with the operation of the remainder of the plant. The engines, boilers and piping were furnished by C. & G. Cooper, of Mt. Vernon, Ohio, and the



FIGS. 1 AND 2. POWER STATION, KNOXVILLE, TENN., ELECTRIC RAILWAY.

counter-shafting by the Holyoke Machine Co., of Worcester, Mass. The plant is rapidly nearing completion and will be in operation some time this month. The installation was designed by Mr. L. H. McIntyre, of the Railway Engineering Department of the Thomson-Houston Electric Co. The electric railway for which this plant is designed is 3.40 miles in length and will operate five motor cars.

FIELD'S MAKE AND BREAK TELEPHONE.

Mr. Stephen W. Field's work in the various branches of telegraphy and electric railroading is probably well known to our readers, but his versatile genius has also led him in the direction of telephony. One of the results of his work here has been the production of a telephone which automatically makes and breaks its circuit with a rapidity too great to be perceptible to the ear; he combines this with a diaphragm in such a way that sound waves projected against it are caused to bridge over the makes and breaks to a degree exactly proportional to the sound waves' rapidity of succession.

The accompanying engraving, Fig. 1, shows two such diaphragms, D and M, supporting respectively two contact points, E and G. One diaphragm is supported above the other and is kept in a state of tension by connection with a fine wire, C, of considerable resistance.

It will be seen that the circuit of battery, B, passes normally through the insulated metal frame, J, of the telephone, and the wire, C, to the diaphragm, D. It will also be observed that there is a short circuit, by way of the wire I, between the contact point, G, and the frame, J. The strain of the wire, C, is normally sufficient to separate the contact points, E and G, but when the switch, A, is closed and the current from battery, B, traverses wire, C, the latter will elongate and allow the points to come in contact.

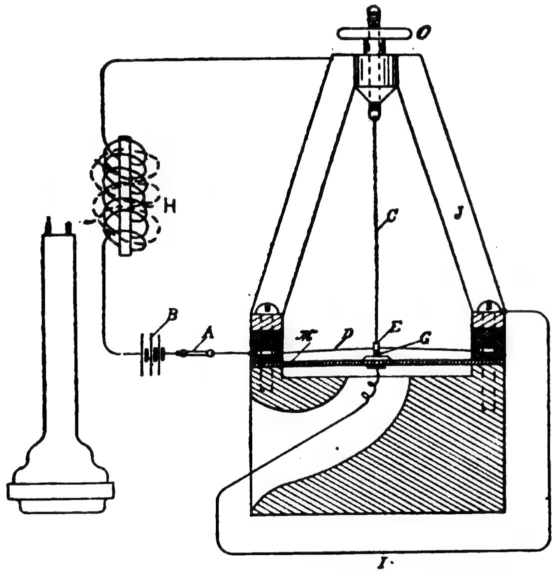


Fig. 1.—Field's Make and Break Telephone.

The current will thus be shunted around wire, C, through a path of approximately no resistance, with the result of cooling and contracting C and separating the contact points.

The function of the device is, in fact, that of a circuit-breaker of such rapid action under the influence of the current of the battery, B, that the vibrations are outside the receptivity of the ear. It follows that the sound waves striking the diaphragm, F, will alter the relative positions of E and G, and tend to prolong their contacts, making audible, and, if in proper sequence, articulate speech.

In Fig. 2 is shown an arrangement for applying the same idea to a carbon transmitter for the purpose of increasing its sensitiveness. In this construction the carbon, which is mounted on the diaphragm, is kept in contact with a corresponding platinum contact-piece by means of a fine wire under tension attached to the diaphragm. The contact expands the wire C, thereby tending to break the circuit; but the consequent cooling of the wire contracts the same and closes the circuit.

With the construction here illustrated an equilibrium is set up between the elongation of the wire, C, and the resistance at the carbon contact, the result being that the pressure of the carbon is kept automatically at the most delicate point and a self-adjusting carbon transmitter is obtained. The changed thermostatic condition of the primary circuit is brought about in this construction by a rupture of the circuit, due to the elongation of the resistance-wire, or, rather, by an increase in the resistance of the circuit, and not, as in the other form, by the introduction of a shunt around the resistance-wire.

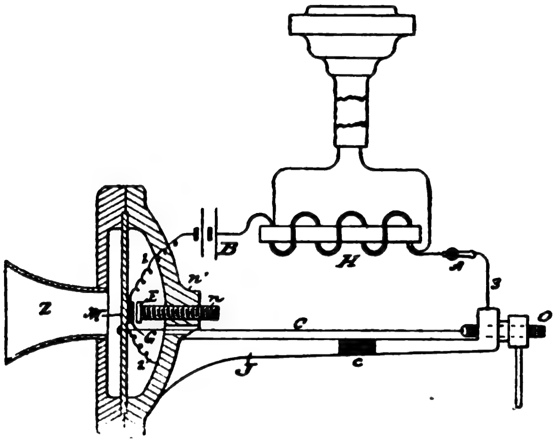

Fig. 2.—Field's Make and Break Telephone.

The makes and breaks of the automatic circuit-breaker produce no audible effects upon the circuit by reason of the great rapidity with which they follow each other. That is to say, the normal vibrations of the circuit-breaker, considered with respect to their capacity to reproduce sounds, are neutral or inharmonious. That which reduces them to harmony and enables them to reproduce sounds is the combination, with the apparatus which produces them, of devices which bridge over or throw together more or fewer of the inharmonious vibrations and thus alter their natural sequence.

RESISTANCES FOR STRONG CURRENTS.

M. Hess, in *La Lumière Electrique* calls attention to certain considerations in the design of resistances for strong currents. In making coils for resistance tests the choice of a material having a low temperature coefficient is very important; but this is not usually the case with coils intended to stand strong currents, nor indeed is high specific resistance a desirable thing. M. Hess shows that if two coils of equal resistance are designed to stand the same current without rising above a given temperature, the coil of higher specific resistance is shorter, while the diameter and volume of the conductor are greater; the ratio in all three cases being the cube root of the ratio of the specific resistance. Thus, if the second coil has 27 times the specific resistance of the first, its length is one-third that of the first, while the diameter of, and the volume occupied by, the wire are each three times as great. Unless, therefore, the second material costs only one-third that of the first, it is cheaper to construct the coil of the better conducting substance.

The Pond Engineering Co. have now opened branch offices in Seattle, Washington, and Dallas, Texas. This company, who make a specialty of constructing steam plants for electrical and power purposes, now cover the West very thoroughly and are doing a large and increasing business.

TESLA'S NEW ALTERNATING MOTORS.

For some time past Mr. Nikola Tesla, whose previous work in alternating current motors is well known, has been engaged upon the study of these machines in order to develop efficient methods for operating them on two wires instead of three, and still without the use of a commutator.

The general principle upon which these machines are designed is based on the well-known fact that if a magnetic core, even if laminated, be wound with a coil and a current be sent through, the magnetization of the entire core does not immediately ensue, the magnetizing effect not being exhibited in all parts simultaneously. This Mr. Tesla attributes to the fact that the action of the current is to energize first those laminæ or parts of the core nearest the surface and adjacent to the exciting coil, and from thence the action progresses towards the interior. A certain interval of time, therefore, elapses between the manifestation of magnetism in the external and the internal sections or layers of the core.

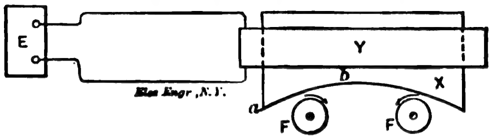

Fig. 1.—Tesla Alternating Motor.

If the core be thin or of small mass this effect may be inappreciable, but in the case of a thick core, or even of a comparatively thin one, if the number of alternation be very great, the time interval occurring between the manifestations of magnetism in the interior of the core and in those parts adjacent to the coil is more marked, and in the construction of such apparatus as motors which are designed to be run by alternating currents, Mr. Tesla has found it desirable, and even necessary, to give due consideration to this phenomenon and to make special provisions in order to obviate its consequences.

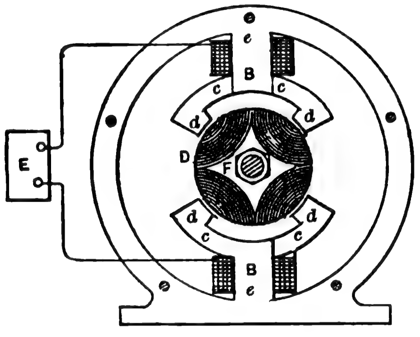

Fig. 2.—Tesla Alternating Motor.

On the other hand, by taking advantage of this very action or effect, and, by rendering it more pronounced, Mr. Tesla utilizes it in the operation of motors in general. This he effects by constructing a field in which the parts of the core that exhibit at different intervals of time the magnetic effect imparted to them by alternating currents in an energizing coil are so placed with relation to a rotating armature as to exert thereon their attractive effect successively in the order of their magnetization. By this means there is secured a result similar to that which Mr. Tesla has heretofore attained in the previous types of his motor, in which, by means of one or more alternating currents, he produces a rotation or progression of the magnetic poles or points of maximum attraction of the field of force.

The general principle involved in the action above mentioned is illustrated in the simple motor shown in Fig. 1. Here X represents a large iron core composed of a number of sheets or laminæ of soft iron or steel. Surrounding this core is a coil, Y, which is connected with a source, E, of rapidly varying currents.

Let us consider now the magnetic conditions existing in this core at any point, as b, at or near the centre, and any other point, as a, nearer the surface. According to Mr. Tesla, when a current impulse is started in the magnetizing coil, Y, the section, at a, being close to the coil, is immediately energized, while the section, at b, which, to use a convenient expression, is "protected" by the intervening sections or layers between a and b, does not at once exhibit its magnetism. However, as the magnetization of a increases, b becomes also affected, reaching finally its maximum strength some time later than a.

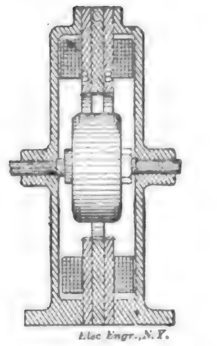

Fig. 3.—Tesla Alternating Motor.

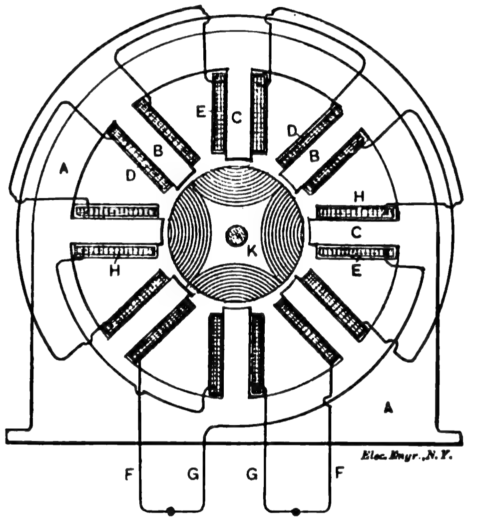

Fig. 4.—Tesla Alternating Motor.

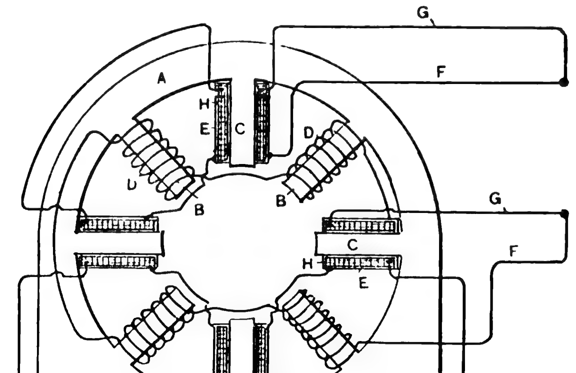

Fig. 5.—Tesla Alternating Motor.

Upon the weakening of the current the magnetization of a first diminishes, while b still exhibits its maximum strength, but the continued weakening of a is attended by a subsequent weakening of b. Assuming the current to be an alternating one, a will now be reversed while b still continues of the polarity first imparted. This action contin-

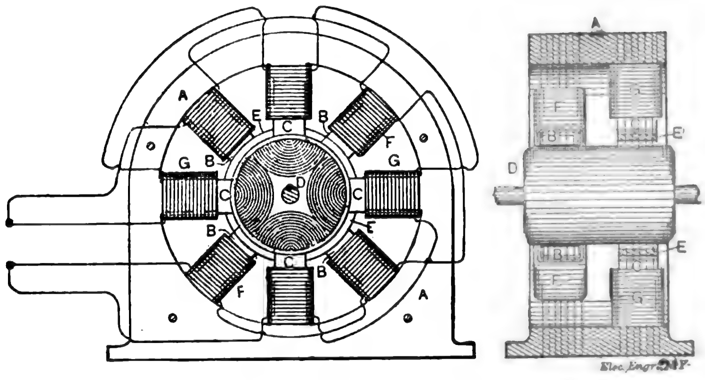
ues, the magnetic condition of b following that of a in the manner above described.

If an armature, for instance, a simple disk mounted to rotate freely on an axis, be brought into proximity to the core, a movement of rotation will be imparted to the disk, the direction depending upon its position relatively to the core, the tendency being to turn the position of the disk nearest to the core from a to b, as indicated in Fig. 1.

This action or principle of operation has been embodied in a practicable form of motor, which is illustrated in Fig. 2. Here A represents a circular frame of iron, from diametrically opposite points of the interior of which the cores project.

Each core is composed of three main parts B, B and C, and they are similarly made with a straight portion *e*, around which the energizing coil is wound, a curved arm or extension *c* and an inwardly projecting pole *d*.

Each core is made of two parts B B, with their polar extensions reaching in one direction and a part C between the other two and with its polar extension reaching in the opposite direction. These cores are wound with coils D, which are connected in the same circuit either in parallel or series and supplied with an alternating current by a generator E represented diagramatically. Between the cores or their polar extensions is mounted an armature F wound with magnetizing coils G that are closed upon them-



FIGS. 6 AND 7.—TESLA ALTERNATING MOTOR.

selves, similar to those in the older types of Mr. Tesla's motors.

The operation of the motor is as follows: When a current impulse or alternation is sent through the coils D, the sections B B of the cores being on the surface, and in close proximity to the coils, are immediately energized. The sections C, on the other hand, are protected from the magnetizing influence of the coil by the interposed layers of iron B B.

As the magnetism of B B increases, however, the sections C are also energized, but they do not attain their maximum strength until acertain time subsequent to the exhibition by the sections B B of their maximum.

Upon the weakening of the current the magnetic strength of B B first diminishes while the sections C have still their maximum strength; but as B B continue to weaken, the interior sections are similarly weakened.

B B may then begin to exhibit an opposite polarity, which is followed later by a similar change on C, and this action continues.

B B and C may, therefore, be considered as separate field magnets, being extended so as to act on the armature in the most efficient positions, and the effect is similar to that in Mr. Tesla's other forms of motor, viz., a rotation or progression of the maximum points of the field of force. Any armature, such, for instance, as a disc mounted in this field, would rotate from the pole first, to exhibit its magnetism to that which exhibits it later.

In following out the ideas stated above, Mr. Tesla has applied them to a class of motors in which two or more sets of energizing magnets are employed and in which by artificial means a certain interval of time is made to elapse between the respective maximum or minimum periods of their magnetic attraction or effect. This has already been applied to the operation of Mr. Tesla's three-wire motors. In the present instance Mr. Tesla employs a motor with two sets of energizing or field magnets, each wound with coils connected with a source of alternating currents, but forming two separate paths or circuits. The magnets of one set are protected to a certain extent from the energizing action of the current by means of a magnetic shield or screen of laminated iron interposed between the magnet and its energizing coil.

The shield is properly adapted to the conditions of particular cases so as to shield or protect the main core from magnetization until it has become itself saturated and no longer capable of containing all the lines of force produced by the current. By this means it will be seen that the energizing action begins in the protected set of magnets, a certain arbitrarily determined period of time later than in the other, and that by this means a practically economical difference of magnetic phase may readily be secured.

The nature and operation of this motor will be readily understood by reference to the accompanying illustration.

The engraving, Fig. 4, shows the simplest form of this type of machine. The cores B form one set of magnets and are energized by coils D, while the cores C, forming the other set, are energized by coils E, and the coils are connected in series with one another, in two derived or branched circuits F G respectively.

Each coil E, it will be noted, is surrounded by a magnetic shield H, which is composed of an annealed insulated or oxidized iron wire wound on the coils in the manner indicated, so as to form a closed magnetic circuit around the coils and between the same and the magnetic cores C.

Between the pole pieces or cores B C is mounted the armature of the closed-circuit coil type.

The operation resulting from this arrangement is as follows: If a current impulse be directed through the two circuits of the motor, it will quickly energize the cores B, but not so the cores C, for the reason that in passing through the coils E there is encountered the influence of the closed magnetic circuits formed by the shields H. The first effect is to effectively retard the current impulse in circuit G, while at the same time the proportion of current which does pass does not magnetize the cores C, which are shielded or screened by the shields H.

As the increasing electromotive force then urges more current through the coils E, the iron wire H becomes magnetically saturated and incapable of carrying all the lines of force, and hence ceases to protect the cores C, which become magnetized, developing their maximum effect after an interval of time subsequent to the similar manifestation of strength in the other set of magnets, the extent of which may be arbitrarily determined by the thickness of the shield H, and other well known conditions.

From the above it will be seen that the apparatus or device acts in two ways. First, by retarding the current, and second by retarding the magnetization of one set of cores, from which its effectiveness will readily be seen.

Many modifications of the principle here embodied have been made by Mr. Tesla, one only more of which we may notice here. This is illustrated in Fig. 5, and is similar in all respects to that above described, except that the iron wire H, which is wrapped around the coils E, is in this case connected in series with the coils D. The iron wire coils are connected and wound so as to have little or no self-induction, and, being added to the resistance of the circuit F, the action of the current in that circuit will be accellerated while in the other circuit G it will be retarded.

Still another type of motor constructed by Mr. Tesla is one with a field magnet having two sets of poles or inwardly projecting cores and placed side by side so as practically to form two fields of force, and alternately ar-

ranged, that is to say, with the poles of one set or field opposite the spaces between the other. The free ends of one set of poles are then connected by means of laminated iron bands or bridge pieces of considerably smaller cross-section than the cores themselves, so that the cores all form parts of complete magnetic circuits.

When the coils on each set of magnets are connected in multiple circuits from an alternating machine electromotive forces are set up in each circuit simultaneously, but the coils on the magnetically bridged or shunted cores will have, by reason of the closed magnetic circuits, a high self-induction which retards the current, permitting at the beginning of each impulse but little current to pass. On the other hand, no such opposition being encountered in the other set of coils, the current passes freely through them, magnetizing the poles on which they are wound.

As soon, however, as the laminated bridges become saturated and incapable of carrying all the lines of force, which the rising electromotive force, and consequently *increased* current, produce, free poles are developed at the ends of the cores, which, acting in conjunction with the others, produce rotation of the armature.

The construction by which this is accomplished is shown in the accompanying engravings, Figs. 6 and 7.

The frame of the motor A, is built up of sheets of iron punched out to the desired shape and bolted together with insulation between the sheets. When complete the frame makes a field magnet with inwardly projecting pole pieces B and C. To adapt them to the requirements of this particular case, these pole pieces are out of line with one another, those marked B surrounding one end of the armature, and the others C the opposite end, and they are arranged alternately; that is to say, the pole pieces of one are set in line with the spaces between those of the other sets.

The pole pieces C are connected or shunted by bridge pieces E.

The coils F and G are connected in series, respectively, in two circuits which are branches of a circuit from an alternating machine, and they are so wound that the circuit of coils G will have a higher self-induction than the other circuit or branch.

The function of the shunts or bridges E, is that they shall form with the cores C a closed magnetic circuit for a current up to a predetermined strength, so that when saturated by such current and unable to carry more lines of force than such a current produces, they will, to no further appreciable extent, interfere with the development by a stronger current of free magnetic poles at the ends of the cores C.

In such a motor the current is so retarded in the coils G and the manifestation of the free magnetism in the poles C is delayed beyond the periods of maximum magnetic effect in poles B. The result is that a strong torque is produced and the motor operates with approximately the power developed in a motor of this kind energized by independently generated currents differing by a full quarter phase.

TESLA'S TRANSFORMER FOR MOTOR WORK AND FOR CONSTANT CURRENT.

In the early forms of alternating motor brought out by Mr. Tesla the construction embodied a series of coils traversed by currents differing a quarter phase from one another. This has in some forms required three wires from the generator to the motor, but in order to avoid this Mr. Tesla has recently constructed a converter specially designed to be used in connection with his motor, and in which the difference of phase required is spontaneously brought about. This converter also possesses the valuable property that it operates with a constant current for all loads imposed upon the secondary.

In transformers as at present constructed it is found that the electromotive force of the secondary very nearly coincides with that of the primary, being, however, of opposite sign. At the same time the currents, both primary and secondary, lag behind their respective electromotive forces, but as this lag is practically the same in the case of each, it follows that the maximum and minimum of the primary and secondary currents will nearly coincide, but differ in sign or direction, provided the secondary be not loaded, or if it contain devices having the property of self-induction.

On the other hand, the lag of the primary behind the impressed electromotive force may be diminished by loading the secondary with a non-inductive or dead resistance, such as incandescent lamps, whereby the time interval be-

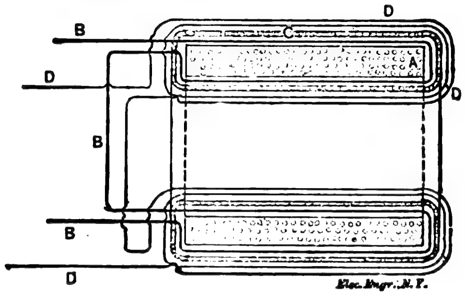


FIG. 1.—NEW TESLA CONSTANT CURRENT TRANSFORMER.

tween the maximum or the minimum periods of the primary and secondary currents is increased. This time interval, however, is limited, and the results obtained by phase difference in the operation of such devices as Mr. Tesla's alternating current motors can only be approximately realized by such means of producing or securing this difference, as above indicated. For it is desirable in such cases that there should exist between the primary and secondary currents, a difference of phase of 90 degrees, or in other words, the current in one circuit should be maximum when that in the other circuit is minimum.

To more nearly and perfectly attain to this condition Mr. Tesla secures an increased retardation of the secondary

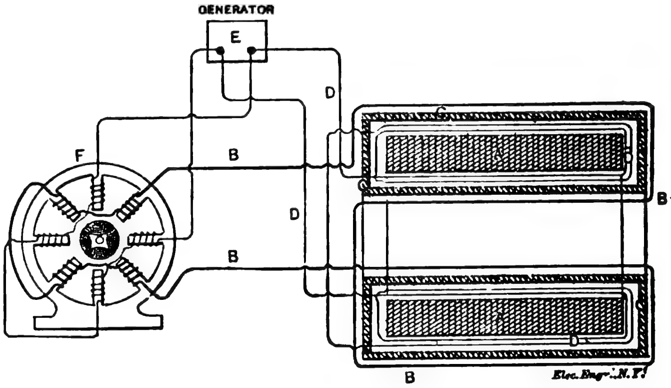

FIG. 2.—NEW TESLA CONSTANT CURRENT TRANSFORMER.

current in the following manner: Instead of bringing the primary and secondary coils or circuits of a transformer into the closest possible relations, as has hitherto been done, he protects in a measure the secondary from the inductive effect of the primary by surrounding either the primary or the secondary with a comparatively thin magnetic shield or screen.

Under these conditions, as long as the primary current has a small value the shield protects the secondary, but as soon as the primary current has reached a certain strength, which is arbitrarily determined, the protecting magnetic shield becomes saturated and the inductive action upon the secondary begins. It results, therefore, that the secondary current begins to flow at a certain fraction of a period later than it would without the interposed shield, and since this retardation may be obtained without necessarily re-

tarding the primary current also, an additional lag is secured and the time interval between the maximum or minimum periods of the primary and secondary currents is increased.

Mr. Tesla has also discovered that such a transformer, may, by properly proportioning its elements, be made to yield a constant current at all loads.

In the accompanying illustrations, Fig. 1 is a cross-section of a transformer embodying the above idea.

A A is the main core of the transformer composed of a ring of annealed iron wire. Upon this core is wound the secondary circuit B B. This latter is then covered with a layer of annealed iron wires C C, wound in a direction at right angles to the secondary coil. Over the whole is then wound the primary coil D D.

From the nature of this construction it will be obvious that as long as the shield formed by the wires C is below magnetic saturation, the secondary coil or circuit is effectually protected or shielded from the inductive influence of the primary.

When the strength of the primary reaches a certain value, the shield C, becoming saturated, ceases to protect the secondary from inductive action and current is in consequence developed therein. For similar reasons, when the primary current weakens, the weakening of the secondary is retarded to the same extent.

In the engraving, Fig. 2, the core A is built up of insulated iron plates or disks. The primary circuit D is wound next to core A. Over this is applied the shield C, which in this case is made up of thin plates of iron properly insulated and surrounding the primary, forming a closed magnetic circuit. The secondary B is wound over the shield C.

In Fig. 2, the primary of the transformer is connected with the circuit of the generator. F is a two-circuit alternating current motor, one of the circuits being connected with the main circuit from the source E, the other being supplied with currents from the secondary of the transformer.

M. ABDANK ON AMERICAN ELECTRIC RAILWAYS.

At the last meeting of Société Internationale des Electriciens, held in Paris, M. B. Abdank-Abakanowicz delivered a lecture on Electric Railways in America in which he dealt at length with details of the various systems employed in this country at the present time. M. Abdank's lecture was illustrated by means of a large number of lantern slides of American roads, and his discourse was voted a great success. With American electric railway work thus prominently brought out in France, it ought to be followed up by actual demonstration, and we believe that much could be done by our railway builders in the introduction of their work in France.

BIMETALLIC WIRES.

The Société Fonderies, Laminoirs et Tréfileries of Joinville le-Pont, says the *Bulletin Internationale de l'Electricité*, is now manufacturing bimetallic wires for telegraph, telephone, or other purposes, of which tests, made by the French Post Office authorities, show the following results :

	Number of coils tested.			
	1.	2.	3.	4.
Diameter........	1.97 mm.	1.88mm.	1.89mm.	1.95mm.
Breaking stress..	493lb.	493lb.	449lb.	603lb.
Lengthening.....	16.17 mm.	26.23mm.	19.20mm.	19.21mm.
Weight..........	57.2lb.	55.7lb.	55.2lb.	55lb.
Resistance per kilometre in ohms at Odeg. cent..	8.66	9.69	8.98	9.52

It appears that a bimetallic wire of 19/10 has the same conductivity as a copper wire of 15/10, and the same breaking stress as a copper wire of 25/10.

A NEW SWITCH FOR OVERHEAD ELECTRIC RAILWAY WORK.

We illustrate on this page a new overhead switch for electric railway service of a very simple and practical design. The accompanying illustrations will explain its workings. Fig. 3 is a view of the plan of the switch ; A B and C B represent the two tracks. In Fig. 1 the car is traveling along the track A B. When the trolley wheel

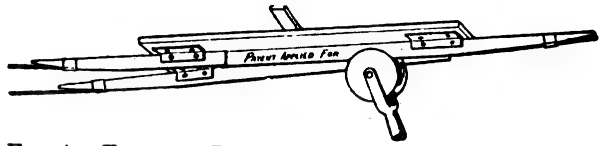

Fig. 1.—Electric Railway Overhead Wire Switch.

reaches the point E, it opens a space wide enough to allow the trolley wheel to pass. After the wheel has passed, the fin springs back into its original position. When the car is traveling on track B C, as shown in Fig. 2, the fin E D is passed over to E C, allowing the trolley wheel to pass along the track B C.

Practical experience has demonstrated the impossibility

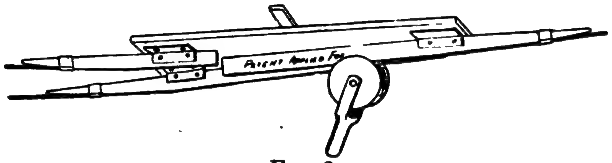

Fig. 2.

for the trolley wheel to jump the track, no matter at what speed the car may be running. The base on which the fins are placed is galvanized sheet iron, and the fins, or more properly the switches, are made of the best saw blade steel.

The trolley wires are fastened by clamps to the ends of

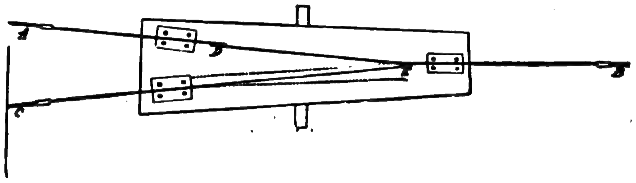

Fig. 3.

the switches, and do not necessitate soldering. The whole is supported by guy wires fastened to lugs extending at right angles to the switch, as shown in Fig. 3. This new device is being introduced by the Illinois Electric Material Co., of Chicago.

STREET NAMES READ AT NIGHT.

It is said that the inspector of streets of St. Louis has adopted a novel method of marking the names of streets, so that the darkest night will not render the way difficult to find. The names of the streets are painted upon the electric light globes and the shadow resulting throws the name upon the ground so plainly that it can be read fifty feet away. The letters on the globe are three-quarters of an inch, and the shadow is five feet wide. An arrangement of this nature would be a welcome one elsewhere.

PHONOGRAMS AND THE CUSTOMS.

Among the decisions in customs cases rendered by the Treasury Department since July 1, copies of which have just been sent by Secretary Windom to all the collectors, is one rendered July 9 affecting the phonograph. It says :

"Phonograph cylinders, imported by mail and which bear upon their surface the impressions made by the stylus of the phonograph when recording letters and messages, are considered as occupying the same position in the transportation of correspondence as the paper sheets upon which communications have heretofore been inscribed or typewritten, and should be treated in the same manner as ordinary mail matter, and subjected to no further inspection by custom officials than may be necessary to protect the interests of the revenue."

THE CHAMBERLAIN BATTERY RACK.

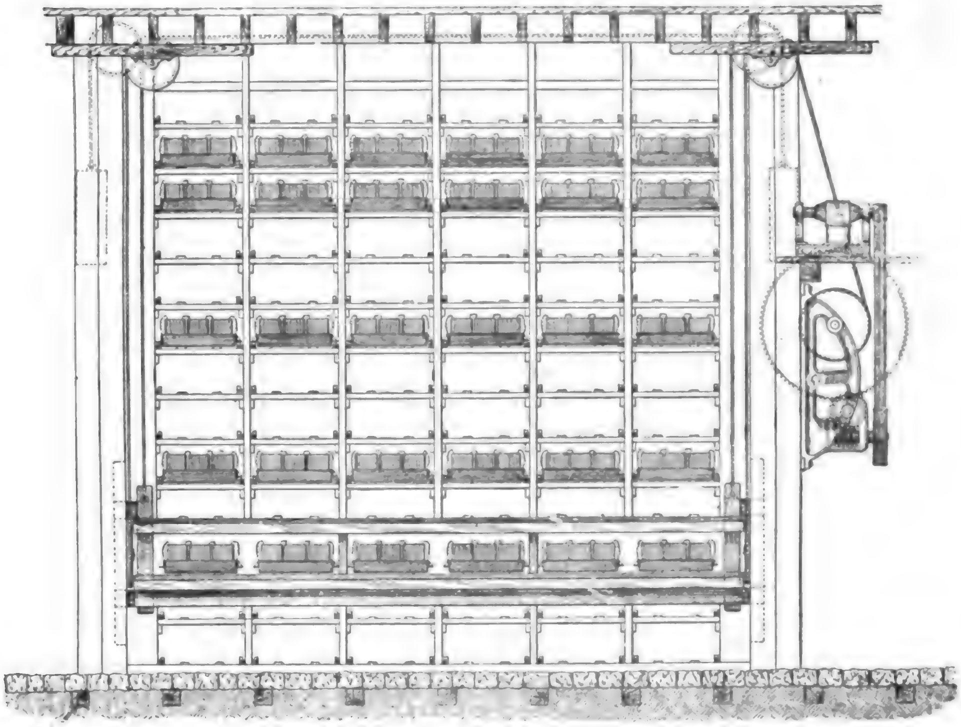
CONSIDERABLE interest has been excited by the perfection which has been attained in the operation of substituting charged for discharged secondary batteries employed in the installation of the United Electric Traction Company at their station, 85th street and Madison avenue, in this city. This work has been brought to its present complete form by Mr. J. C. Chamberlain, and embodies a number of novel and interesting features.

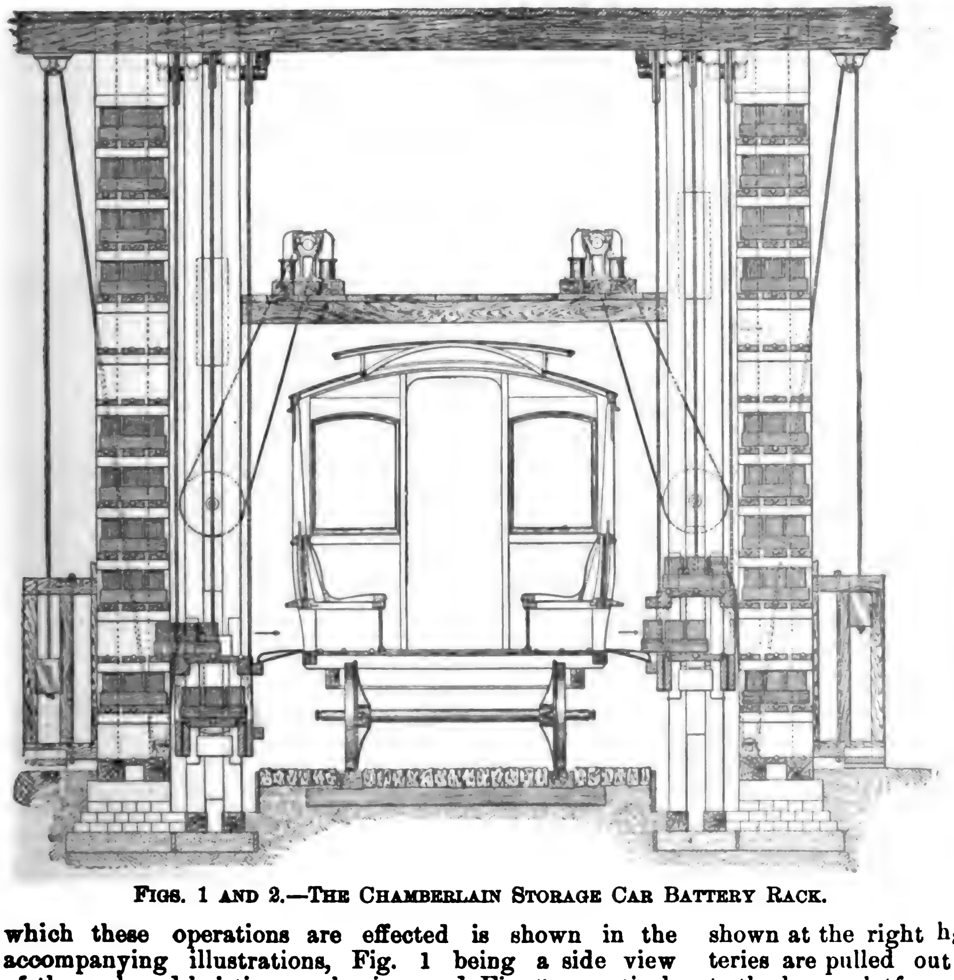
The visitor at the station is impressed with the rapidity and ease of the operation of shifting the batteries. A car having discharged batteries is run into the station, and into a sort of stall between two racks of superimposed shelves; there is a sort of sliding noise, a movement of the elevator platforms on each side of the car, and the car is rapidly run out, leaving the station within three minutes of its entry. In that time a complete set of batteries, having a charge sufficient to carry the car on its journey, to the Post Office and return (11 miles), has been substituted for the exhausted batteries, and the latter have been automatically connected into the charging circuit on the racks, and are again being charged.

The general construction of the racks and hoisting mechanism by which these operations are effected is shown in the accompanying illustrations, Fig. 1 being a side view of the rack and hoisting mechanism, and Fig. 2, a vertical, transverse section, with the car shown in position. The racks have a number of shelves superimposed, as shown, and adapted to receive the drawers of batteries. When the batteries are in place on the shelves they automatically make connections with the charging dynamos, which are not shown in these illustrations. A large number of cells may be packed within the limited floor-room taken up by these racks; the latter are placed far enough apart to receive between them a street car and usually also the hoists. The floor space occupied is but 7 by 24 feet on each side of the car, and there are contained within this space cells enough to do the work of from 130 to 150 horses. It may be fairly said that the stall room these horses would require would be about 6,000 square feet.

A pair of hoists are arranged between the racks and the car, and the hoists on the opposite sides of the car are independently operated by another pair of electric motors shown; the latter motors, however, are only used in elevating the platforms. For lowering them to any place desired, opposite the racks or the car, an ingenious friction brake in the elevator winch is used. By throwing off the motors, and allowing the hoists to drop under the control of the friction brakes, a considerable saving of time is effected.

A charged set of batteries is loaded on the upper platforms of the hoists, in readiness for an in-coming car. When the car is run into the stall, its cove panels are quickly dropped to form a bridge to the lower platform of each hoist, which has been brought into position, as shown at the right hand of Fig. 2. The discharged batteries are pulled out from the car, over this bridge, on to the lower platform, the hoist then dropped to the position





FIGS. 1 AND 2.—THE CHAMBERLAIN STORAGE CAR BATTERY RACK.

shown at the left hand in Fig. 2, and the charged batteries are shoved into place on the car; the panels are then closed up automatically, and the car moves out. The hoists are then raised, the discharged batteries on the lower shelves are run into vacant shelves at the same height on the two racks, and the top platform is re-loaded with charged batteries for the next car.

The shifting can be done rapidly by means of one man on each side; each stands on the platforms on either side, which are connected by rope with the hoists so as to rise and fall with the latter, and so as to be always in position opposite the hoist at whatever part of the rack it may be.

The system has been patented by Mr. Chamberlain in the United States and foreign countries, and the details of the construction have been well worked out. One of the most important of these is the form of binder also patented by Mr. Chamberlain and shown in Fig. 3, which is used for connecting adjacent ends of the two cells of the batteries. It is important that single cells shall be coupled rapidly and removed without disturbing the remaining cells in the same drawer; and also that good electrical contact shall be maintained between the electrode terminals, which are

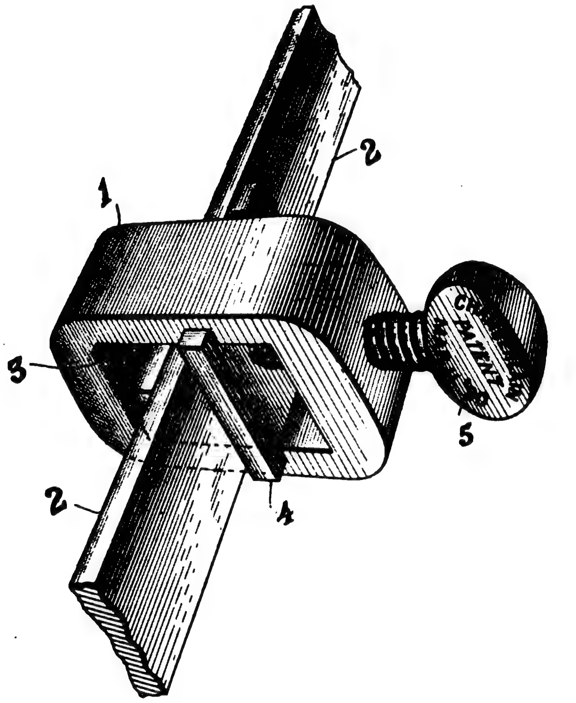


FIG 3.—CHAMBERLAIN'S STORAGE BATTERY CONNECTOR.

connected by the binder. Mr. R. N. Chamberlain is to be credited in part with the solving of this problem. Advantage is taken of the binding action of a hard rubber screw, in a socket of the same material. Referring to Fig. 3, 1 is a loop of hard rubber, which receives the two ends of the electrodes of adjacent batteries, which are represented at 2. A soft rubber cushion 3 is arranged at one end of the loop and a hard rubber washer 4, and hard rubber screw 5, at the other end. By turning the thumb screw the battery terminals are pressed tightly together between the hard rubber washer and soft rubber cushion. The rubber cushion insures the maintenance of such pressure as to prevent any turning of the thumb-screw, and loosening of the electric connection. The materials being entirely impervious to the action of the acid fumes, remain unattacked and constitute a durable and efficient method of connection.

A FLOTILLA OF PERAL SUBMARINE BOATS.

The Spanish Government, after repeated consultations with Lieut. Peral, has resolved to build a small flotilla of the submarine boats invented by that officer. The original intention was to purchase two. The vessels that have been ordered are larger than the Peral, capable of affording accommodations for a crew of from twenty to fifty men. The results of the trial of the Peral showed her to be far superior to the Goubet, the Gymnote, and other vessels of the kind.

CORRESPONDENCE.

CHICAGO.

Objecting to an Electric Factory—The Chicago Edison Company to Burn Hard Coal—Canceling Western Union Railway Contracts.

A NUMBER of the property owners on West Fourteenth street and Blue Island avenue are seeking to enjoin John J. Curran and the Schuyler Electric Company from operating a shop and factory at Nos. 437 and 439 West Fourteenth street. The premises which Curran owns have been leased to the Schuyler Electric Company, who, it is stated, propose to run night and day in order to meet the demand for their product.

Mr. George D. Morgan denies the report which was recently heard concerning the sale of the Morgan tract in Calumet to the Westinghouse Electric Company, and says that no such deal has been contemplated.

The Chicago Edison Company will shortly begin work making some change in their boiler furnaces in order to burn anthracite coal, and thereby abate the smoke nuisance. They burn some twenty-five tons of coal daily. They have not had much success with the employment of smoke consumers, and are satisfied that the best way to eliminate the smoke is to use hard coal.

A bill in equity has been filed in the United States Circuit Court at St. Paul against the Northern Pacific Railroad Company, Western Union Telegraph Company, and the Northwestern Telegraph Company, setting forth that the defendant corporators have failed to carry out the provisions of the acts of Congress of July 2, 1864, and April 10, 1869, in which the railroad company was granted valuable concessions from the United States in lands to the amount of twenty alternate sections through any State. One of the provisions of the act was that the railroad should erect and maintain a telegraph system. Subsequently the Northern Pacific made contracts with the Western Union Telegraph Company, and the complaint alleges that the contracts were beyond the powers of the railroad to make or the telegraph companies to receive and were induced by improper and corrupt considerations, and were against public policy and in violation of the rights of the United States under acts of Congress. The court is, therefore, asked to annul the contracts. The complaint is signed by Attorney-General Miller. The telegraph franchises in question extend over 2,189 miles of railway. The proceeding also denies the right of the Western Union Telegraph Company to succeed to the rights and franchises of the Northwestern Telegraph Company of Kenosha, Wis., the United States Telegraph Company, the Atlantic and Pacific Telegraph Company, the Independent Telegraph Company, the Pacific Telegraph Company, the Overland Telegraph Company, and a number of others the names of which are not specified. The complaint alleges that the Northern Pacific had no right to enter into the contracts with telegraph companies, that it was a breach of public trust and a violation of the Northern Pacific charter rights. The contracts are all declared unlawful because the Northern Pacific Railroad Company is not by and through its own corporate officers and employees maintaining and operating for railroad, commercial, and other purposes telegraph lines, but on the contrary is in all ways disregarding the provisions of the act of Aug. 7, 1888, requiring it to operate its own lines.

CHICAGO, Aug 1, 1890.

BOSTON.

Progress of the New Building of the Edison Illuminating Company—Electric Equipment of the Forthcoming Mechanics' Fair—Damage from the Electric Storm—Less Light in Electric Cars—Richards Electric Company—Proposed Appointment of an Inspector of Electric Wires for City of Boston.

THE addition to the building of the Edison Illuminating Company, of Boston, is rapidly approaching completion, and the brick work of the three new stories is now finished, and work is being done on the flooring. When completed the first floor will be entirely devoted to engines, the second floor to dynamos, the third will be used as a meter room and machine shop, and the fourth as a stock room, while the offices of the company will occupy the fifth floor, which will be tiled throughout. The increase in the underground plant during this spring and summer has been very large, some 20 miles of tubes having been laid down. The back bay district, the South End and the city are now thoroughly covered, and a map of Boston, with the feeders and mains shown therein, represents a perfect gridiron of tubes. The Edison Company are paying great attention to motor business, and every month there is an increase of about fifty horse-power.

The managers of the Mechanics' Fair, to be held in Boston in October and November, will be enabled to make a better arrangement of exhibits than has been possible in previous exhibitions. Heretofore it has been necessary to place all machinery which was to be shown in operation, near the shafting, but the Thomson-Houston Electric Co. is now to place electric motors in any part of the building where power is desired, and this will enable the

managers to give some machines better locations than could be assigned under previous conditions.

Westinghouse, Church, Kerr & Co. have been granted a large amount of floor space, and they will make an important exhibit of engines, stokers and steam supplies.

This week's thunder storm tested the West End Street Railway Company pretty severely, and kept things pretty lively for a time in the various stations. The only serious trouble, however, was the burning out of one armature, but this did not stop the traffic for more than a few minutes, as other machines were immediately cut into circuit.

The Boston *Globe* suggests this week the advisability of having less light in the electric cars which make suburban trips, during the summer, stating that those who ride in the cars would much prefer to sit "in the gloaming" and view the surrounding scenery which is obscured by such a flood of light in the car itself. The suggestion doubtless has its merits, as it is easily observable that there are large numbers of riders in the cars during the warm summer weather, of both sexes, who, apparently, would not object if there were no light at all. In certain conditions, even the electric light has its drawbacks.

The Richards Electric Company is a new concern, organized under the laws of Maine, with a nominal capital of $100,000 $10 shares, $1,000,000, and having an office at No. 3 State street. The company is based upon an improvement in telegraphy invented by Mr. Walter S. Richards of Natick. The inventions are directed toward increasing the efficiency of the telegraphic and fire alarm service through a diminished cost of battery power. It is claimed that 10 cells with the Richards appliance will accomplish the same results as 100 cells as ordinarily applied, and that it saves 90 per cent. of electromotive force. The system has been tested over Western Union wires, between Boston and New York and intermediate points, 25 cells giving the same power as 250 by the old method, and over long distance telephone wires to New York. Boston capitalists have purchased the patents, and propose to develop a commercial business. Among the interested parties are Messrs. Irving A. Evans & Co., Moore & Schley, Bayard Thayer, Albert A. Pope, N. S. Simpkins, Louis Ross, J. Otis Wetherbee, George B. James and John Simpkins, mostly Boston parties. The principle of the device, I understand, depends upon the use of an induction coil in the primary circuit, the line being connected with the secondary coil. An ingenious device is used to prevent both the "makes" and the "breaks" going to line.

Mayor Hart has sent a communication to the aldermen calling attention to the great danger from electric wires, and urging the necessity of the immediate appointment of a supervisor. In calling attention to this matter the mayor says: "A dynamo is as dangerous as a steam engine, and the wires carry this danger all over the city and into our very homes." It is proposed to appoint a wire superintendent at $4,000 a year, his term to run for 3 years.

BOSTON, Aug. 2, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

EFFICIENCY OF THE TRANSFORMER.

[131.]—In common, no doubt, with most engineers on this side of the water, I have read Messrs. Humphrey and Powell's paper on the above subject, reported by you, and have been surprised at the results obtained. The loss by hysteresis comes out astonishingly small. There is one point, however, in the report of the paper which is not clear; and that is the method of measuring the instantaneous values of the primary currents. The instantaneous electromotive force on two lamps in the primary circuit was taken and divided by the resistance of the lamps, the lamps having been previously tested throughout their range, so that a resistance corresponded to each electromotive force on them. There is nothing in the paper to say whether the resistances taken in determining the instantaneous currents were those corresponding to the instantaneous electromotive forces, or to the effective electromotive forces. On looking up Prof. Ryan's classical paper, I find the same uncertainty.

I hardly like to suggest that Prof. Ryan and Mr. Merritt, or Messrs. Humphrey and Powell have made a slip here; but there does seem to be room for an error that would bring out the efficiency too high, especially at light loads when the lamps in the primary would be dull. The resulting determination of the power lost would be chiefly affected by the part of the current curve under the peak of the electromotive force curve, which, assuming the slip to have been made, would be too low. The top of the magnetizing current would come too high, but this would not correct the error, as there is no electromotive force then. I do not see how this possible error could give rise to greater inaccuracy in one paper than the other; even Prof. Ryan's tests of hysteresis losses are small. The hysteresis also varies with the load, which is curious.

Prof. Ryan suggests that at full load the force on the coil shakes the iron. The force should not exist in a transformer, and depends on what Prof. Ryan calls the leakage and not on the total induction through both coils Moreover, if the application of external energy, as in shaking iron, prevents loss from hysteresis appearing in the circuit, it is probable that the energy is lost as before, but is now supplied mechanically. But in the transformer the mechanical energy is itself supplied electrically, and so the loss by hysteresis would not be lessened by the shaking due to forces acting on the coils.

Some of the results in Messrs. Humphrey and Powell's paper look inaccurate. In plate i. the primary current reaches its maximum before the electromotive force is zero. This may be due to excessive Foucault currents. With no Foucault currents, the maximum primary current on open circuit necessarily corresponds with the zero of the electromotive force curve. It is here about .075 ampere. The open circuit current reaches a maximum of .11 ampere under about 800 volts. With Foucault currents eliminated it must there be less than .075, say, .07 ampere. This gives .04 ampere for Foucault currents under 800 volts, and, as the Foucault current curve must be similar to the primary electromotive force curve, with sometimes a very minute lag, due to the primary "leakage," the true magnetizing current can be traced by subtraction. It does not correspond with curve iii. of plate xiii. The Foucault current curve iv. of plate xiii. is impossible; it is leading with reference to the primary electromotive force, that is to say, at some instants the Foucault currents are supplying power to the dynamo. The same phenomenon appears in plate xiv., if I understand it properly.

I mention these points merely for elucidation; American colleges do practical work that puts ours to shame, so it would be unbecoming to attempt to criticise it from this side of the Atlantic.

JAS. SWINBURNE.

WIMBLEDON, LONDON, July 16, 1890.

ELECTRICITY NOT ALWAYS TO BLAME.

[132.]—As usual the cry has gone out that the fire in the Western Union Building was caused by an electric current. It would be most likely a difficult task to prove conclusively that it was not. It would be equally difficult to prove that it was not caused by a lighted match, cigar or cigarette carelessly thrown into some inflammable substance. The chances of the fire having been caused in the latter way are fully as great, if not greater than, in the former; but, of course, the electric current gets the benefit of the doubt.

I remember when I was connected with the Baltimore and Ohio Telegraph Company, I one time discovered an incipient fire among the wires in the battery room of one of the offices. The fire was put out before damage to any extent had been done. The origin of the fire was a lighted tallow dip used by the battery man in the dark recesses of the battery shelves, which had been carelessly placed under some of the insulated wires. Had a conflagration ensued there is no doubt it would have been attributed to the "electric current."

An acquaintance of mine recently informed me that he once thoughtlessly threw a lighted cigar into a waste paper basket. Shortly thereafter he had occasion to leave his office for a few minutes, and upon his return he found the flooring and wainscoting of the office ablaze. The fire was gotten under control before very much damage was done, and as it happened that electric light wires were embedded in the wainscoting near the flooring, at the point of the origin of the fire, the firemen concluded that the "electric current" had been at work.

No doubt in many other instances fires are quite as erroneously attributed to the action of the electric current.

WM. MAVER, JR.

NEW YORK CITY, August 1, 1890.

UNDERGROUND TELEPHONE SYSTEM AT BERLIN.

An extensive underground telephone system is now in course of construction at Berlin, and a large number of cast-iron pipes are being laid by the telegraph department for the purpose. The pipes, which are upwards of 25 miles in length, are to carry from 20 to 90 cables, and vary in diameter from 8 to 16 inches. The cables will be sheathed with iron wires, and contain uniformly throughout 28 conductors of No. 19 copper wire, insulated with impregnated fibre, and (to prevent induction or cross talk) lapped with tin foil. The cables now to be laid are over 90 miles in length, and have 2,520 miles of conductors. The cables are supplied by Messrs. Felten and Guilleaume. Man-holes (405 in number) will be placed at certain intervals for the purpose of facilitating drawing in of the cables and testing conductors. This extensive system, it is estimated, will cost about $500,000. It is hoped that when completed it will suffice for the ever-increasing number of subscribers, who already amount to 15,000.

REPORTS OF COMPANIES.

TROPICAL AMERICAN TELEPHONE CO.

The Tropical American Telephone Co. held its annual meeting at Long Branch, on July 30, when the following directors were chosen:—Chas. Williams, Jr., Col. H. S. Russell, Dr. E. P. Bradbury, J. H. Howard, and Frank W. Harrington. The report of the general manager showed business 50 per cent. in excess of the year before. Stockholders recommended the resumption of dividends and an extra. The question of amount of dividend to be paid will be decided upon at the next directors' meeting.

THE NEW YORK STOCK QUOTATION CO.

The announcement made on the Stock Exchange with regard to the Exchange's acquisition of a controlling interest in the New York Stock Quotation Company reads as follows:—

The New York Quotation Company having been acquired by the New York Stock Exchange is now prepared to furnish its members with prompt and reliable service. The following officers have been elected:—R. H. Thomas, president; A. B. Chandler, vice-president and general manager; George W. Caspar, secretary; P. W. Harding, treasurer. The directors are R. H. Thomas, P. W. Harding, A. B. Chandler, F. W. Gilley, Jr., F. H. Sturgis, W. H. Baker and William L. Bull.

All of the directors of the company except two, namely, A. B. Chandler and W. H. Baker, are Governors of the Stock Exchange. The announcement last week was simply the consummation of negotiations which have been pending for months, and is understood to be the final step in the direction of controlling the Stock Exchange quotations so as to give its own members a preferred service, and limiting their benefits to such individuals and institutions as the Exchange may see fit. Besides the New York Stock Quotation Company, the Gold and Stock Telegraph Company sends out quotations from the Exchange. Negotiations are in progress with this company by which the Exchange will control its quotations also.

STOCKS AND BONDS.

BURLINGTON, IA.—A first mortgage for the sum of $300,000 in favor of the American Loan and Trust Company and against the property of the Burlington Electric Railway Company was recorded at Burlington, Ia., last month. Bonds of $1,000 each, bearing 6 per cent. interest and running twenty years, will be issued for the above amount, the proceeds to be used in converting the old horse car lines into an electric system.

DIVIDENDS.

THE CALIFORNIA ELECTRIC LIGHT CO., of San Francisco, has declared a dividend of 20 cents per share.

NEWARK, N. J.—The Newark Electric Light and Power Co. has declared a quarterly dividend of 1¼ per cent.

FINANCIAL MARKET.

QUOTATIONS OF ELECTRICAL STOCKS.

Mr. F. Z. Maguire, of 18 Wall street, this city, reports the following quotations of August 2, on the New York, Boston and Washington Exchanges:—

NEW YORK:	Bid.	Asked.
Western Union Tel.	83⅞	
Edison Gen. El. Co.	107	
" " " deferred	96	
Consolidated El. Light	60	
Edison El. Ill. Co.	70	
United States El. Light	35	
BOSTON:		
Thomson-Houston El. Co.		53
" " " Pr'ef'd		25
" " " " Series C.		12
" " " " " D.		6½
" " International El. Co.		
" " Welding Co.		
" " European Welding Co.		91
Ft. Wayne Electric Co.	12½	
Telephone.—

American Graphophone		16½
U. S. El. Light (Washington)		164
Eckington & Soldier' Home El. Ry		69

*Ex-Dividend.

METAL AND SUPPLY MARKET.

COPPER PRICES.

There was hardly any trading in copper on the Metal Exchange during the week July 28–August 2. At the close of the week margins were called at 17 cents. On Friday, August 1, the visible stock of copper on hand was estimated at 73,000 tons, substantially the same as on July 1. Following are circular prices of copper, tin and lead August, 1890, and August 2, 1889:

	August 1, 1890.	August 2, 1889.
Straits tin, spot	20.80	19.75
Straits tin, Oct	20.90	19.80
Lake copper, Aug	17.00	11.75
G. M. B. copper, Aug	—	8.75
Domestic lead, spot	4.45	3.97½
Domestic spelter, Aug	5.40	—

SOCIETY AND CLUB NOTES.

TOPICS TO BE DISCUSSED AT THE CAPE MAY MEETING.

Mr. Allen R. Foote, secretary of the National Electric Light Association, reports that the Committee on Papers have selected the following topics and have invited the persons named to prepare a paper or open a discussion on the subject assigned him:

1. *Electrical Industries and the World's Columbian Fair*, J. P. Barrett, Chicago.
2. *Electric Light as Supplied to Steam Railroads*, W. H. Markland, Altoona, Pa.
3. *Standards of Economy in the Generation of Power and Steam Under Best Conditions*, Editor of *Power and Steam*, New York, H. M. Swetland.
4. *Triple Expansion High Speed Engines for Central Station Work*, Williams, Beloit, Wis.
5. *The Model Boiler-Room and the Duties of a Fireman*, Jarvis B. Edson, New York.
6. *Ferranti Station at London, England*, Caryl Haskings, Lynn, Mass.
7. *The Proper Care and Management of Alternating Currents*, T. Carpenter Smith, Philadelphia.
8. *Distribution of Energy by Alternating Currents and Transformers and the Proper Method of Proportioning Conductors*, A. L. Rohrer, Lynn, Mass.
9. *The Proper Basis for Determining Electric Motor Rates*, H. L. Lufkin, New York.
10. *Actual Cost of Furnishing Arc Lighting (1,200 c. p. and 2,000 c. p. Lamps) Under the Best Possible Conditions*, J. C. Ayer, St. Louis.
11. *Municipal Ownership of Electric Lighting Plants*, M. J. Francisco, Rutland, Vt.
12. *Accidents in Electric Lighting Stations and Plants*, Prof. Charles R. Cross, Boston.
13. *Care and Labor in Electric Light Stations and Its Value*, A. J. DeCamp, Philadelphia.
14. *How Can the National Electric Light Association Best Serve the Interests of Central Station Companies?* C. R. Huntley, Buffalo, N. Y.

REPORTS TO BE CONSIDERED.

1. Committee on National Insurance Rules,
George Cutter, Chairman.
2. Committee on Electrical Data,
A. J. DeCamp, Chairman.
3. Committee on Copper Tariff,
Charles A. Brown, Chairman.
4. Committee on Underground Conduits and Conductors,
Joseph E. Lockwood, Chairman.
5. Committee on Revision of Constitution.
M. J. Francisco, Chairman.
6. National Committee on Legislation,
Allen R. Foote, Chairman.
7. Committee on Relations Between Manufacturing and Central Station Companies,
Marsden J. Perry, Chairman.

8. Executive Committee,
C. R. Huntley, Chairman.
9. Finance Committee,
John A. Seely, Chairman.
10. Secretary and Treasurer's Report,
Allen R. Foote.

At each session of the Convention a call will be made for the proposal of questions to be discussed at a subsequent session and for the introduction of resolutions to be considered at a subsequent session when reported by the Committee on Resolutions for action.

Members desiring to take part in the discussion of any subject stated or proposed, who send their names to the Secretary previous to the time appointed for its consideration, will be called upon by the President and be given time before the subject is opened to the Convention. By this means every member can secure recognition and time to express his views fully on any subject that may come before the Convention. It is not expected that those to read papers or open the discussions will monopolize all the time that can be given to, or exhaust, the subject. The best results from discussions can be obtained only when every member who has an idea to explain, a suggestion to offer, or a bit of experience to relate regarding any subject before the Convention, will avail himself of the regulation, stated above, to secure recognition and time that will give him an opportunity to make his contribution to the common stock of information.

An announcement of the order of proceedings will be made for each day on the preceding day. The subjects and reports will be taken up in the order there named, and will be held under consideration until finished. Each afternoon session will be prolonged until the Calendar for the day has been cleared.

The last session will be an Executive Session to be attended by active members only. The business to be brought before the session will be:—

1. Secretary and Treasurer's Report.
2. Report of Finance Committee.
3. Report of Executive Committee.
4. Action on Report of Committee on Revision of Constitution.
5. Election of Executive Committee.
6. Selection of Next Place of Meeting.

LEGAL NOTES.

PROPULSION BY STORAGE BATTERIES.

FINAL REJECTION OF FAURE'S APPLICATION FOR A PATENT ON IMPROVEMENTS IN THE APPLICATION OF SECONDARY BATTERIES AS A MOTIVE POWER.

Decision of the Supreme Court, D. C.

The application was filed May 25, 1887. No. 239,318. The invention is stated in the specification to consist—

in the application of secondary batteries or accumulators preferably carried by a vehicle, or upon one of a train of vehicles, to supply electrical energy to one or more electro-magnetic motors also carried by or upon the said vehicle, or one or more of a train of vehicles, combined with means for varying the amount of energy supplied by the battery.

The original claims were twenty-two in number, and were drawn to cover the propulsion of vehicles by means of a secondary battery of the Faure type, whether or not the battery should be mounted upon the vehicle.

After various actions by the Examiner and amendments by the applicant the claims were reduced to two, introduced by amendment January 30, 1888, viz.:

1. The combination of a moving vehicle propelled by rotary motion imparted to a shaft or axle, a secondary battery having a plate, support, or conductor, coated, combined or associated with a mechanically-applied active or absorptive substance, an electro-magnetic motor electrically connected to said battery and a mechanical connection between the shaft or axle of the vehicle and the moving part of the motor, substantially as described.

2. The combination of a wheeled vehicle propelled by mechanical motion imparted to a shaft or axle, a secondary battery carried by the said vehicle and consisting of two or more plates, supports or conductors, combined or associated with a mechanically-applied active or absorptive substance, a dynamo electric motor, electrically connected to said battery, and a mechanical connection between the shaft or axle of the vehicle and the moving part of the motor, substantially as described.

The amended application was rejected by the Primary Examiner upon reference to the French journal, *L'Electricité*, of August 5, 1880 (vol. iii., pp. 253 and 254), containing a description of a boat propelled by an electric motor supplied with current by a Reynier battery. The Reynier battery is also described in the same volume of *L'Electricité* as a battery that is regenerated after exhaustion by an electric current. The Examiner held that, it being old to propel vehicles by secondary batteries, it could not be patentable to employ a particular kind of secondary battery for that purpose.

Upon appeal the Examiners-in-chief not only affirmed the decision of the Primary Examiner, but increased its scope; holding that,

One battery of any known kind having been used in a combination substantially the combination of the claims, for the purpose of the combination, the substitution of another kind of battery in the place of the one already used;—for example, a secondary in place of a primary, or one type of secondary battery in place of another type of secondary battery,—involves simply a double use of the substituted battery and produces no new invention.

The case was then appealed to the Commissioner of Patents, whose decision of February 21, 1890, affirmed the decision of the Board of Examiners-in-Chief. The official summary of the Commissioner is as follows:—

1. INVENTION—WANT OF NOVELTY—STATE OF THE ART.

Where the prior art disclosed that it was old and well known to apply electrical energy to the propulsion of a boat by means of a battery, mounted upon the boat, capable of being regenerated, and also to propel a locomotive engine or vehicle by means of electricity supplied by a primary battery mounted thereon, and that such contrivances were successful in the sense of being operative, although they involved great expense and were not successful commercially, *Held* that no invention was exercised in applying the Faure secondary battery to the propulsion of vehicles, no adaptation being required to make it available for the specified purpose.

2. SAME—SAME.

Nothing was better known than that a source of propulsive energy for vehicles must, if mounted upon the vehicle, have great efficiency in proportion to its weight, and when the Faure battery appeared, possessing qualities which were antecedently recognized as necessary for propulsion under the conditions named, nothing was more obvious than that, to the extent to which it possessed these qualities, it was adapted for vehicle propulsion when mounted upon the vehicle.

3. PROTECTION OF INVENTIONS—PROLONGATION OF MONOPOLY.

The first inventor is entitled to all the benefits which spring from the obvious uses of his invention. Others may patent the means by which they adapt it to uses not antecedently obvious; but the inventor is entitled to a free field for the exercise of all the qualities and special adaptations that belong to his invention. So, too, the public are entitled to practice the invention in all its obvious utilities when the patent has expired and may not lawfully be debarred from the enjoyment of it by subsequent patents seeking to monopolize uses which, although special, are at the same time recognized by persons skilled in the art as pertaining to it.

4. FAURE'S INVENTION.

To the Faure secondary battery must be ascribed all the success which attends upon all the uses to which skilled mechanics have the capacity to apply it.

In the text of his decision the Commissioner says:

In the proposed application of the Faure battery no adaptation is required to make it available for the specified purpose, no change is made in the battery nor in any other of the enumerated parts of the old combinations, and the specification dwells upon the excellencies of the patented battery for the purpose described and claimed.

In the argument of counsel great stress was laid upon the fact that Faure first achieved success. The obvious reply is that his success was the success of his battery. To illustrate, if the first person who applied a steam-engine of any kind to the use of propelling a steamboat made an operative success, but had been unable to attain a commercial success on account of the great relative weight of the engine, the inventor who should remove the difficulty by inventing a steam-engine of superior power relative to weight and operating upon a new principle would achieve success through the medium of his superior engine, and not through the combination of the engine with the boat propelled. To the Faure battery must be ascribed all the success which attends upon all the uses to which skilled mechanics have the capacity to apply it. * * * To use a better battery in a combination in which an inferior one had been previously used is not to make a new combination. Of course if means of combining the old instrumentalities are called into existence in connection with the substitution of the superior for the inferior source of energy, such new means would be patentable if they involved invention. But in that case the range of patentability would not extend beyond the means employed to adjust the improved source of energy to the old combination.

Applicants finally appealed to the Supreme Court of the District of Columbia, where the case was ably and comprehensively argued by Counsel for Faure, Mr. Frederick H. Betts and Mr. W. B. Vansize.

Mr. Justice Hagner delived the opinion of the court July 7, fully sustaining the decision of the Commissioner of Patents.

INVENTORS' RECORD.

Patents issued July 29.

Conductors, Conduits and Insulators:—*Conduit for Telegraph Cables*, W. R. Patterson, 433,025. *Insulating Compound*, I. Babinowicz, 433,215. *Pole for Supporting Electric Wires*, L. Atwood, 433,266.

Dynamos and Motors:—*Dynamo Electric Machine*, H. W. Spang, 433,051. *Regulator for Dynamo-Electric Machines*, P. P. Belt, 433,269. *Brush-Holder for Electrical Machines*, W. S. Belding, 433,390. *Armature for Dynamos*, W. S. Belding, 433,391. *Blank for Armature Coil-Guards*, W. S. Belding, 433,392. *Commutator for Dynamos*, W. S. Belding, 433,393. *Magnetic Coupling Device*, T. M. Foote, 433,400. *Variable-Speed Gearing for Electric Cars*, T. M. Foote, 433,401. *Reversing Gear for Electric Cars*, T. M. Foote, 433,402. *Electric Railway*, R. M. Hunter, 433,407, 433,408 and 433,409.

Galvanic Battery:—*Galvanic Battery*, H. J. Brewer, 432,973.

Lamps and Appurtenances:—*Electric Light Fixture*, F. H. Aldrich, 432,-965. *Electrode for Arc-Lamps*, L. Saunderson, 432,041. *Holder for Incandescent Electric Lamps*, A. Schirner, 433,371.

Medical and Surgical:—*Electrical Syringe*, J. B. Woodward, 433,384.

Miscellaneous:—*Electric Cut-Out*, H. A. Chase, 432,978 and 432,979. *Fuse-Block and Lightning Arrester*, H. A. Chase, 432,980. *Automatic Electric Switch and Cut-Out*, C. R. Doyle, 432,988. *Electro-Magnetic Cut-Out*, B. J. Noyes, 433,022. *Safety Cut-Out*, C. E. Scribner, 433,045. *Loop-Key*, C. E. Scribner, 433,046. *Safety Cut-Out*, M. S. Shapleigh, 433,187. *Thermal Cut-Out*, A. Bernstein, 433,229. *Electric Switch*, J. F. McLaughlin, 433,360. *Electric Heat-Regulating System*, F. M. Sparrow, 433,375. *Electro-Magnetic Transmitter*, J. T. Williams, 433,381. *Lightning Arrester*, A. Wurtz and O. H. Baldwin, 433,430.

Railways and Apparatus:—*Electric Railway*, R. M. Hunter, 433,170. *Electric Motor Traction Wheel*, A. L. Parcelle, 433,180. *System of Electrical Transportation*, A. L. Parcelle, 433,181. *Electric Apparatus for Railways*, J. B. Odell, 433,210. *Automatic Electric Train Signal*, A. W. Peppy, 433,216. *Contact Device for Electric Railways*, F. J. Sprague, 433,425.

Secondary Batteries:—*Separator for Secondary Batteries*, 433,174, W. P. Kookogey.

Telegraphs:—*Dynamo-Telegraphy*, F. W. Jones, 433,082. *Telegraphic Circuit*, A. C. Robbins, 433,421.

Telephones and Appliances:—*Test Circuit for Multiple Switch-Boards*, C. E. Scribner, 433,047. *Telephone*, S. D. Field, 433,120. *Combination Telephone-Key*, C. E. Scribner, 433,424.

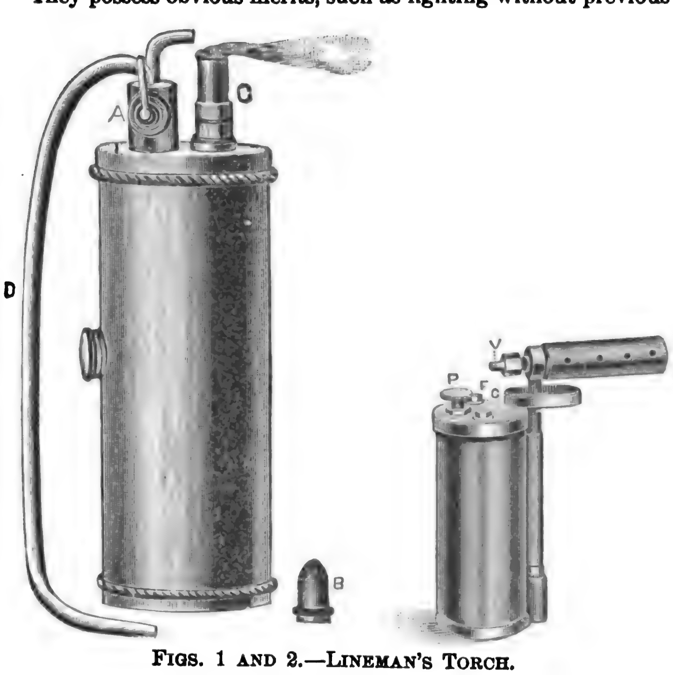
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

LINEMEN'S TORCH EQUIPMENT.

Upon nothing so much as thorough equipment does the s ıccess of what may be called the tactics of construction depend. Designing is the strategy of electrical engineering; putting the result into operation is the tactics. The appended illustrations are of appliances which contribute in a great degree to the excellence of linemen's work. Figs. 1 and 2 are two forms of the Walsh continuous gasoline torch, made by the Walsh Manufacturing Company, of Chicago.

They possess obvious merits, such as lighting without previous



FIGS. 1 AND 2.—LINEMAN'S TORCH.

heating, fine workmanship, portability, immunity from accident and safe to the point of being turned upside down without the least danger. The heat is intense and has a wide range of regulation effected by shields attachable to the nozzle by a screw thread and quickly shifted as required. One gives a thin, lancelike flame, long or short, and the other a large brush-shaped flame for large work, with the same adjustibility of length as the smaller flame.

Its joints in lead pipe are shown, by a large number of tests, much stronger than the pipe itself, and it can be used four hours without the least intermission, without inconvenient heating. Its durability is shown by the fact that torches over two years in constant use are not yet in need of repairs.

The cost of maintenance ranges from one to four cents per day dependent upon the proportion of the work.

THOMPSON'S PATENT CHART.

Mr. E. P. Thompson, of Temple Court, Beekman street, has compiled and published a very interesting and useful chart, intended for the use of U. S. inventors, showing the fees, terms of duration, populations, terms of caveat, cost of trade marks, cost of securing patents, etc., in this country and all the countries of the world where it is desirable to obtain patent protection. Mr. Thompson has put an immense amount of work on this chart and has copyrighted it. It is a thing of great value for reference. Mr. Thompson utilizes the other side of the chart to give some interesting information about his own large patent practice.

THE NEW INSULATED WIRE OF THE AMERICAN CIRCULAR LOOM COMPANY, OF BOSTON.

Line wire is a subject at all times interesting to an electric station superintendent. When he has got his station into as perfect running condition as possible, economical boilers, economic steam engine, and efficient dynamos and lamps, he next wants to know where he can find a good line wire, one that will save the leakage of current from his lines, which means a saving of energy, and consequently a saving of dollars and cents. There are many good line wires in the market, he finds, and there are continually new ones being brought out. Among the most recent wires is that manufactured by the American Circular Loom Company of Boston, which is worthy of notice, as the insulating covering is put on in a different way from any other wire now manufactured. This woven insulated wire has attracted considerable attention of late, and the writer had the pleasure recently of making a thorough examination of the method of manufacture. The factory is situated at North Hanover. Mass., and is well equipped with plenty of water and steam power. Nearly all line wires have their insulation composed of cotton. jute or hemp, or other fibrous material, braided on the copper by the well known braiding machines, and then soaked in some insulating compound. The insulation of American Circular Loom Company's wire, however, is not braided but woven on by means of circular looms of improved type, the invention of Mr. Charles T. Stetson. The cotton is No. 12 single, and is twisted together at the factory in as many ply as is necessary for the size of wire to be covered. The twisted cotton is then put in the loom, which works exactly the same as looms for weaving flat fabrics, so many bobbins forming the woof, and so many bobbins being so shaped as to fit the shuttles which circulate round the loom and forming the warp. The looms are about four feet in diameter, and the mechanism is extremely simple and interesting to the eye of a mechanic. The shuttles move round very rapidly, the woof being moved up and down by means of eccentric rods on revolving discs, so that the warp passes below one thread and above the next one. When completed the woven insulation is very hard and firm, and has the appearance of a canvas jacket, like a piece of sail cloth around the wire. The wire is then taken to the compounding house, where a special compound is forced into the cotton insulation by a secret process, so effectually that every fibre of cotton is thoroughly impregnated. It is then polished and finished and wound on drums for shipment. When finished, the insulated wire has a peculiarly tough finish, and is particularly capable of withstanding a large amount of abrasion, and is at the same time as waterproof as any line wire with cotton fibre in the insulation can be, and is to a very extraordinary degree fire-proof. The American Circular Loom Company have their offices at 620 Atlantic avenue, Mr. H. H. Brooks being general manager, with Mr. A. T. Clark as treasurer, and the company are reported to have large orders ahead, and are working to their full capacity.

THE BREWER CONDUIT ELECTRIC RAILWAY SYSTEM.

Attractive as the conduit system of operating electric railways has proved to be, it cannot be looked upon yet in the light of a success. Had the methods in operation up to date been reliable and economical, as the situation demands, there would unquestionably have been a rapid extension of the work. But conduit railroading has lingered and languished in a quite remarkable manner. Mr. W. J. Brewer, C. E., an Englishman, and member of the London Chamber of Commerce, Engineering Section, has had his mind on the subject for some time past, and his visits to this country have impressed him with the desirability of a good practical conduit system, such as could be introduced in large cities, and compete with overhead wires in economy of installation, while doing away with the objections of which one hears so much. Mr. Brewer has submitted his system to our inspection, and we are free to confess that it strikes us as having many elements of great merit and success. One of the points aimed at has been infrequent exposure of the conduited conductors, thus ensuring higher insulation and less leakage or fear of short circuit. Another striking feature is the fact that in adopting the system an established line need not make heavy expenditures to do so, but is compelled to change only one rail of the track. Evidently the cost of construction is minimised, as well as the cost of maintenance. As soon as Mr. Brewer's patents are issued, we hope to enter upon a detailed description of his highly ingenious methods and ideas.

Mr. Brewer has also designed an ingenious frictionless bearing for the axles which not only effects ease in running but allows of ready starting of the car.

YALE & TOWNE MFG. CO.

The Yale & Towne Mfg., Co. of Stamford, Conn., have contracted for a 40 h.p. Edison dynamo, which is to supply current for 2 motor cars on 1800 feet of tramway track and for motors in various parts of their big factory. The motors are of the Sprague type.

C. & C. ELECTRIC MOTOR CO.

The output of motors during the present summer, by the C. & C. Electric Motor Co., 402 and 404 Greenwich street, this city, has been far in excess of their expectations. Until recently their announcements stated that they had 8,000 motors in operation. It now reads "over 10,000 motors in actual operation." In fact, the total of the sales of the last six weeks is equal to that of any previous entire year. Such a state of affairs must be extremely gratifying to the concern.

THE EMPIRE CITY ELECTRIC CO.

Owing to the rapid exhaustion of the last edition of their handsome catalogue, the Empire City Electric Co., of 15 Dey street, have been compelled to issue a notice to that effect, stating that they are now getting up a new and more complete one, which will be distributed as soon as ready. In the meantime they will be happy to give prices, information, etc., with regard to any part of their large stock of standard goods and specialties.

WENSTROM CONSOLIDATED DYNAMO AND MOTOR CO.

The above company, through their selling agents, Chadbourne, Hazelton & Co., 416-18-20 Walnut street, Philadelphia, have now issued an extremely tasteful and effective pamphlet relative to their systems of light and power. It is printed in tint on the best paper, and has steel plate engravings on the cardboard covers, which are tied with variegated silk cord. The pamphlet is well illustrated and contains a good description of the Wenstrom machine. A list is also given of some of the plants now in operation, and the closing pages contain the announcements of the various associated enterprises engaged in developing the system.

INTERIOR CONDUIT AND INSULATION CO.

The Interior Conduit and Insulation Co. have been obliged to enlarge their office facilities at No. 16 Broad street, by acquiring another large room on the same floor. It will be occupied this week by Mr. Edwin T. Greenfield, electrician of the company, and by draughtsmen under his instructions. The company are now waiting the delivery of ten new machines for the manufacture of interior tubing alone, and with the aid of these they hope to be ready by the first of next week, to catch up with their orders.

THOMSON-HOUSTON WORK.

The new office building of the Thomson-Houston Co., on Centre st., Lynn, will be occupied at once. A day or two ago the company assembled the largest generator for the transmission of power it has ever built. It is 250 horse-power, 8½ feet high and weighs 23 tons. It is now being tested. It is for railway work, and will go into the West End Co.'s power house in Boston. The new factory, J, for the manufacture of mining machinery, under C. J. Van Depoele's coal-cutting patents, has begun operations this week. When fully running it will have 100 men. Mr. Van Depoele is in charge for the present, and he will have as his assistant A. J. R. Fiego, an electrician who has assisted him in developing the inventions. The lines for the new oil house have been staked out.

THOMSON-HOUSTON SALES IN THE WEST.

We give below the July sales in the West of the Thomson-Houston Chicago office:—*Arc*—Highland Park Electric Co., Highland Park, Ill., 30 lights; Capital Gas Co., Sacramento, Cal., 50 lights; T-H. E. Lt. & Pr. Co., Meridian, Miss., 25 lights; Hyde Park, Ill., 50 lights; Studebaker Bros., So. Bend, Ind., 200 lights; Famous Mfg. Co., Indiana, 30 lights; C. C. Travis, Owosso, Mich., 60 lights; Oakland Gas Lt. & Heat Co., Oakland, Cal., 50 lights; Chillicothe Water & Lt. Co., Chillicothe, Mo., 70 lights.

Incandescent.—Iowa Institution for Feeble Minded Children, Glenwood, Iowa, 500 lights; Ionia Elec. Co., Ionia, Mich., 1300 lights; H. W. Michael, Leadville, Colo., 150 lights; Thomas Elec. Lt. & Pr. Co., Ottawa, Ill., 1300 lights; Chicago Arc Lt. & Pr. Co., Chicago, Ill., 1300 lights; Cleveland Elec. Lt. Co., Cleveland, O., 1300 lights; Hyde Park T-H. Lt. Co., Hyde Park, Ill., 2,600 lights; Aspen Mining & Smelting Co., Aspen, Col., 50 h. p. generator; C. C. Travis, Owosso, Mich., 650 lights; Chillicothe Water & Lt. Co., Chillicothe, Mo., 500 lights; Wm. Ritchie Co., Chicago, 200 lights.

THE EDISON-LALANDE BATTERY.

A very pretty and original pamphlet on the Edison-Lalande battery has been issued by the Edison Manufacturing Co., James F. Kelly, sales agent, 19 Dey street, setting forth the merits and claims of the Edison-Lalande battery. It comprises a large amount of information on the subject, including a number of curves and tables that bring out graphically the qualities of the battery. At the foot of many of the pages are quoted testimonials from users of the battery on all classes of work, and there is a consensus of approval as to the results its gives.

NEW YORK INSULATED WIRE CO.

The above company, of 649 and 651 Broadway, this city, have issued another edition of their excellent catalogue and price list. It is in many respects the best piece of work of its kind, being small, neat, very complete, well arranged, and giving not only copious information as to the Grimshaw wire and cables but a variety of data that one needs constantly for reference.

NEW WESTINGHOUSE PLANTS.

The Monongahela City Electric Company, an organization lately established, has just concluded negotiations with the Westinghouse Electric and Manufacturing Company for alternating current incandescent apparatus of 750 lights capacity.

The new Westinghouse alternating current arc light system is in favor at Moline, Ill., and with the Jarecki Manufacturing Co., Erie, Pa., and is being installed now to the extent of twenty-five lights in each place.

Washington, Georgia, is to be illuminated by the alternate current system of electric lighting. The Westinghouse Electric and Manufacturing Company has been awarded the contract for the installation of its apparatus for a capacity of five hundred lights.

The Westinghouse Electric and Manufacturing Company has just sold a forty-light dynamo of its alternate current arc light system to go to Three Rivers, Michigan, there to be used by the electric lighting company of the town for the nightly dispensing of brightness.

CHESTER FOUNDRY AND MACHINE CO.

The Brotherhood three-cylinder engine is built in this country by the Chester, Pa., Foundry & Machine Co., who are the sole manufacturers for the United States. The company also do a large business in boilers and wrought iron work and heavy machinery. So well are they employed, with old and new orders, they now have work on hand for two years ahead.

THE WORLD'S FAIR—MR. J. P. BARRETT'S NOMINATION WIDELY ENDORSED.

Among Eastern signatures to the petition to the Board of Directors of the World's Columbian Exposition, requesting the selection of Mr. J. P. Barrett, electrician of the city of Chicago, to have practical charge and control of the electrical department of the Exposition, are the following:—

IN NEW YORK AND VICINITY.

W. J. Holmes, supt. Western Union Tel. Co.; Geo. M. Phelps, president THE ELECTRICAL ENGINEER; D. J. Carson, sec'y So. Bell Telephone and Telegraph Co.; Samuel Insull, second vice-president, Edison General Elec. Co.; Edw. H. Johnson, prest. Interior Conduit and Ins. Co.; J. H. Bunnell & Co.; E. H. Cutler, mgr. Elektron M'f'g Co.; The Empire City Electric Co., H. G. Madden, ass't gen. mgr.; Henry D. Stanley, sec'y Bridgeport Brass Co.; C. H. Lane, electrical supplies; G. A. Hamilton, Western Electric Co., N. Y. City; Thos. Whiteside Rae, C. E.; THE ELECTRICAL ENGINEER, New York; Allen R. Foote, Washington, D. C.; Townsend Walcott, electrical engineer; Franklin L. THE ENOS VOTE RECORDER.

The House Committee on Rules gave a hearing on July 28 to John A. Enos, an inventor, who seeks to have an appropriation of $60,000 made to defray the cost of installing his patent electric voting machine in the House of Representatives. Mr. Enos stated that during this session there have been over 300 roll calls, each consuming thirty minutes' time, or an aggregate of thirty working days, and he asserts by the use of his machine twenty-five days would have been saved.

WESTERN TRADE NOTES.

MR. THOS. GRIER, one of the managing engineers of The National Engineering Bureau, The Rookery, Chicago, has gone East to Philadelphia on a short vacation.

THE SPERRY ELECTRIC CO. are turning out their well known system of arc lighting as rapidly as possible, and find it difficult to keep pace with their large and numerous orders, so generally has the system, which is very durable and efficient, come into use.

MR. G. L. TEEPLE, a graduate of Cornell '88, who has been associated with the Western Electric Company, has resigned his position there and accepted the instructorship in Electrical Engineering in Dartmouth College.

THE CHICAGO INCANDESCENT LAMP CO., 13–17 N. Jefferson street, are about to double the capacity of their lamp factory. They manufacture incandescent lamps for any system, and their product is in large demand. Their lamps show a long life and high efficiency, and do not blacken. The demand has become so large that an increase in their manufacturing facilities has been rendered imperative.

MR. CHAS. G. ARMSTRONG, manager of the house goods department of The Great Western Electric Supply Company, has returned from his trip East, where he has purchased a very large and complete stock of electrical supply goods and specialties for electric light, telephone, telegraph, electric railway and power work. He has completed arrangements to handle the specialties of the New Haven Clock Company.

THE ILLINOIS ELECTRIC MATERIAL CO., The Rookey, Chicago, are doing a brisk business in electric supplies, Bishop white core wire, and other specialties. They have in hand a new switch, which will be placed on the market very shortly, and which possesses features of marked merit and advantage. They expect to do a very large business as soon as the Fall trade opens up. Their aim is to supply the best possible goods at reasonable prices.

MR. FRANK B. RAE, of the Detroit Electrical Works, was in town and a guest at the Electric Club last week. His company are very busy equipping a new surburban electric road, running out of Ft. Worth, Texas, with a complete Rae system of electric traction. The cars will be 35 feet long, with vestibule ends and equipped with double tracks, to each of which is geared a 30 horse power Rae motor, with which a speed of 25 miles an hour will be attained. They will be of the very finest finish and workmanship ever turned out by the Pullman Car Company.

THE ELECTRICIANS' TIME CO., 167 Dearborn street, Chicago, have issued a handsome little two-page circular enumerating the objects of their business, which are to furnish electricians and others with reliable watches protected from magnetism, which at the present time are a necessity, and also to supply other goods, such as diamonds, jewelry, silverware, etc., on easy payment if desired or for cash. A number of weighty testimonials are added, and the cuts of their special watches cause the circular, which is printed in colors, to present a very neat and attractive appearance.

MR. J. K. PUMPELLY, of the Pumpelly Storage Battery and Electric Motor Co., is now manufacturing a cell in which the electrolyte is absorbed by a special cellulose fibre which is placed in it between the plates and filling it up. The evaporation of the electrolyte is thereby greatly decreased and the resistance of the cell is not materially increased. The electromotive force also remains remarkably constant during the whole duration of the discharge. It is impossible for the acid to splash out, and the battery is admirably adapted for street car service.

MR. GEORGE H. R. PREBLE, of Tacoma, Wash., is in town and expects to return there in a week's time. He has been extensively engaged in electric work in that part of the country for some time, especially in street railway work. He has been examining with special interest the electric street railway supplies and specialties manufactured by the Electric Merchandise Company, of this city, and was found by your representative looking into these things, which were being explained by Mr. Mason, the general manager of the company. Mr. Preble when he returns will certainly be able to speak of the good things and latest developments in the art which he saw at their offices.

THE THOMSON-HOUSTON ELECTRIC CO., Michigan avenue, Chicago, are enlarging their offices on a most extensive scale, and will have one of the finest suite of offices in Chicago. They now occupy the entire building. On the ground floor will be located the central station, isolated lighting and stationary motor departments and the offices of Mr. Small. The partition heretofore dividing the floor from the stairway will be removed, and the large entrance space will be used as offices for the sales agents. Upstairs on the next floor, which is being beautifully decorated and finished in red oak, will be located the offices of Mr. B. E. Sunny, the Street Railway Department, Mr. Bailey, Mr. Wheeler, and Mr. Horne, the Engineering Department and a very handsome reception room, illuminated with 48 incandescent ceiling lights, tastefully arranged. This floor will be finished in terra cotta and blue papering, and carpeted to match. All the lights are regulated in sets by switches placed out of sight and easily accessible. The top floor will be used for light repairing and armature winding, and the dynamo repairs and heavy work will be done in the basement.

NEW ENGLAND TRADE NOTES.

THE NEW ENGLAND WIRING AND CONSTRUCTION CO. have received the contract for wiring the Middlesex County Court House at East Cambridge, Mass., for about 350 lights. Interior conduit will be used wherever practicable, and they will also furnish all the fixtures.

KENDAL & SLADE, Boston, have received the contract for the outside construction work for the Lynn and Boston Railroad Co. The line will be about eight miles long and will extend from the Lynn station to Wyoma. Single and double track will be used at different parts, and the system will be the overhead single trolley of the Thomson-Houston Electric Co.

THE TRIPP MANUFACTURING CO., of Boston, have recently made a shipment of their celebrated anti-friction journal bearings to the Chicago and Northwestern R. R. for passenger car service. Also electric car trucks to Concord Horse R. R.; Wilkes Barre and Suburban Street R. R.; Citizens' Cable Traction Co., Pittsburgh, Pa. The company is now manufacturing electric trucks for the following roads:

West Side Street R. R., Milwaukee, Wis.; Citizens' Street R.R., Indianapolis, Ind.; St. Paul City R. R.; Tacoma and Stellacoon R. R., Tacoma, Wash.; Vancouver and Electric R. R. and Lighting Co., Vancouver, B. C. The trucks manufactured by this company, equipped with Tripp's bearings for reason of simplicity and durability, are rapidly being adopted.

MR. WILLIAM D. WARNER, of 135 Pearl street, Boston, reports that he is furnishing large quantities of "Albumural" to electric light stations for painting their walls a pure white. Albumural is a fireproof and waterproof paint, and is used where ordinary kalsomining has proved unsatisfactory. It has an extremely white, glossy finish and never rubs off. Among the most recent electric companies to adopt Albumural are: Brookline Electric Company, Brookline, Mass.; Edison Electric Company, Newport, Mass.; Portsmouth Electric Company, Portsmouth, N. H.; North Adams Electric Light Company, North Adams, Mass., and many others. When applied it gives the station a clean and neat appearance, and being of an intense whiteness it brightens up the interior and saves a good deal of unnecessary lighting.

ST. LOUIS TRADE NOTES.

BROWNELL AND WRIGHT CAR CO. have just finished the shipment of 12 motor cars for the Cincinnati Street Railway Co., and 10 motor cars for the inclined Plain Plane Railway, all of Cincinnati. They are also engaged on large orders for cable and horse cars, and report that they are always crowded with orders.

MR. GUIDO PANTELEONI, Western representative of the Westinghouse Electric Co., reports the sale of a 60-alternating arc plant for Waco, Tex.; 80 arc and 1,500 incandescent for Ogden, Utah; and 40 arc with 500 incandescent for Carrollton, Mo.; also an isolated plant of four 500-light direct current dynamos to Moore, Bullene, Emery & Co., large dry goods merchants of Kansas City, Mo.

THE ST. LOUIS OFFICE of Westinghouse, Church, Kerr & Co. are putting in two 100 h. p. Westinghouse compound automatic engines, with line shafting and clutch pulleys of the latest improved pattern; also a 100 h. p. horizontal two plate tubular boiler for the Belleville Electric Light and Power Co., Belleville, Ills. They are also installing a 100 h. p. Westinghouse compound automatic engine at Lebanon, Mo., for the Lebanon Light and Water Co.

Scientific knowledge makes the great man greater, adding to his powers, while it guards the weaker brethren from many follies.—Fleeming Jenkin.

THE ELECTRICAL PROPULSION OF VESSELS.

IN his able and interesting article that we publish this week, dealing with the subject of electric launches, Mr. Frederick Reckenzaun remarks that in a discussion of this topic we have to deal not with a new invention, but with an aggregate of inventions and experiments. Work in this field goes back, in fact, to the days of Jacobi, and antedates almost the whole of the development, that has now become so enormous, of the electric motor ashore. To-day, however, fifty years after the first successful demonstrations were made with crude apparatus, electrical propulsion for vessels remains an utter novelty to the vast majority even of educated and traveled people. In England, as might be expected of a country not only surrounded by salt water but submerged half the year in fresh, electric launches have been given a pretty good trial, and Messrs. Immisch have done themselves great credit by establishing a fleet on the upper Thames. But in this country, except the "Magnet," owned by Mr. Reckenzaun himself, we know at this time of no launches at all. There was one on the lake that broke its banks and destroyed Johnstown, but we have heard nothing of it since that memorable flood.

The time has certainly come when electric launches should be extensively used in this country. Having ourselves made trips around New York Bay and the Narrows, as well as up the Kills, with Mr. Reckenzaun, we can speak with knowledge of the great pleasure and comfort derivable from the operation of such craft, as well as of the absence of so many features that make boating disagreeable. The main consideration left now is that of expense, and on this point, the article gives some details that are trustworthy as well as figures that are well within the mark. Such fleets of electric launches as he proposes could easily be started, say, for example, on the Harlem in this city; on the Schuylkill at Philadelphia; on the Charles River at Boston; on the Potomac; on the great lakes at such points as Chicago, Cleveland, and Detroit; and on the ornamental waters of city parks all over the country. This is surely a field that deserves looking into and is worthy of development.

Moreover, a great many of the yachts in this country have their isolated plants, and to them a launch charged at fitting times, and always ready for lowering and for service, would be a great boon and convenience. This class of work, too, comes near to that required in the navy; and it is not to be overlooked that electric launches are already becoming part of the fleets of the leading maritime nations. Mr. Reckenzaun, who has long made a special study of the subject, points out other departments of usefulness, and we can readily believe that, once available, these boats would be in demand in many unexpected quarters. As it is, the sphere of ordinary commercial operations is large enough in itself to warrant attention being paid to the subject by those who are watching for new opportunities in electrical engineering.

TRIED AND FOUND WANTING.

MR. ELBRIDGE T. GERRY and his colleagues of the Commission appointed by the legislature of New York "to investigate and report the most humane and practical method of carrying into effect the sentence of death in capital cases," included in their report opinions which they had sought from judges, legal officers, electrical experts and physicians. Among them Dr. Wm. T. Plant, of Syracuse, thought that with proper apparatus and with proper skill electrical execution might be made certain and safe from mishap, "but," he said, "only actual trial can determine whether it is best."

The actual trial has been made upon Kemmler with formidable and elaborate apparatus of the kind advised by one of the most distinguished of the experts whose opinions were reported by the Gerry Commission. Making due allowance for the sensational character of the reports of the daily press, it is quite certain that the death of the victim at Auburn was not instantaneous, that respiration was resumed some minutes after the application and cessation of the current, that the current was turned on again, this time despatching the convict, but not without burning his flesh at the points of contact with the electrodes, and not till he had exhibited to the spectators meanwhile evidences of vital struggle not less revolting than those usually seen upon the gallows. This is the pitiable outcome, so far, of three years' work, beginning with the investigation and report of Mr. Gerry's Commission, followed up by the officious Medico-Legal Society, and accompanied by a series of experiments upon rabbits, dogs, neat cattle and horses at the hands of *soi disant* electricians and a few young physicians; the purpose of the work being to discover the "most humane and practical" way to kill a capital convict.

The execution of Kemmler though horrible, was not more horrible than many hangings have been. But the New York *Tribune* is mistaken in saying that "the only alternative is hanging." Mr. Gerry's Commission itself directed attention, in its report, as we have before pointed out in these columns, to a third method, to wit, poisoning, by use of the hypodermic needle, which was rejected because, in the words of the report:—"The use of that instrument is so associated with the practice of medicine, and as a legitimate means of alleviating human suffering, that it is hardly deemed advisable to urge its application for the purpose of legal executions against the almost unanimous protest of the medical profession." Poison in the form of liquid or gas can be administered with as much certainty of painless death as can be predicted of electricity, and probably more; and its employment for executing criminals would be far more "practical," requiring no machinery or elaborate apparatus. It would also insure immunity from all disfigurement of the body. It would be neither sensational nor experimental—two attributes of the method just put into operation that fully justify the conclusion that the philanthropic Commission and the legislature have not succeeded in providing the most humane and practical means for carrying out the sentence of death.

CENTRAL STATION STATISTICS.

The electrical figures in the census of 1880 were of the most meagre and unsatisfactory kind. The telegraph data was the most complete, because ten years ago telegraphy was the great electrical industry. But the telephone was hardly noticed, and all the rest was a blank—an undiscovered world where the census agent had never set foot. This year, however, the indications are that the census of electrical industries will be of the most complete nature possible. We have just received from Mr. Allen R. Foote a set of the schedules for central stations, and find them in every way excellent. We trust that the figures asked for will be supplied fully, or if not fully, with the nearest approximation. The result can only be as Mr. Foote says: "An exhibit of American genius, skill and enterprise, of which the nation will be proud, and which will be the marvel of the country." The other schedules prepared by the special agent are equally well drawn, and we hope that the figures from each industry will leave no cause for complaint on the ground of incompleteness or inaccuracy. The central station schedules will be distributed in three or four weeks, and we bespeak for Mr. Foote the utmost cordiality of support in his arduous work.

Series Storage Batteries.

The practice of joining each set of plates in a storage battery in multiple—the first employed in the art—has become so universal that all other possible methods were, until recently, entirely neglected. It would appear, however, that at last proper attention is being given to this detail, in the employment of plates, which are placed in series so that each cell has an E. M. F. depending on the number of plates which it contains. On first consideration it might seem immaterial so far as the watt-hour capacity of a given cell is concerned whether its plates be arranged in parallel or series, but when we consider many special applications, especially those involving transportation of the cells, as on street cars, certain advantages in favor of the series cells become more apparent. Greater economy of operation can frequently be obtained by the use of high E. M. F. and small current for a given amount of electrical energy expended, and in such cases the series battery, with its increased E. M. F., can be applied with great benefit. Again, in portable installations, the smaller number of cells required is an important factor. The series cell designed by Mr. Dey and described in this issue ought to fill a place which until now has remained unoccupied, but which seems capable of considerable extension.

Electric Railways and Ocean Cables.

The interference of the electric railway operated parallel to the lines of the Commercial Cable Co., which was pointed out by Mr. Charles Cuttriss in our last issue, has called forth an interesting contribution from Mr. T. D. Lockwood, in which he discusses the probable explanations of the apparently anomalous case. Thus, while admitting the possibility of leakage from the earthed railway conductors, Mr. Lockwood emphasizes the point that the existing arrangement cannot strictly be considered as a complete metallic circuit. But he goes further and shows that the static arrangement and conditions can easily be made to account for the phenomena, aggravated as they are and almost entirely due to the burial of the cable conductor in the earth. Naturally, Mr. Lockwood, with his telephonic leanings, considers the electric railway as the trespasser in this matter, and holds that the most simple remedy to be applied should come from that quarter, by the application of the double overhead trolley system. While the efficacy of this method cannot be gainsaid, it seems doubtful if it will be applied, after recent decisions of the courts in similar cases. On the other hand, with the nature and cause of the disturbance thoroughly understood and verified, the remedy can, with probably far greater facility, be applied to the cable.

Converting Alternating into Continuous Currents.

In the early days of alternating current apparatus, when its practibility as compared with that for continuous current was the most prominent topic before electrical engineers, the objections that were raised to it were numerous. Among the more prominent of these was the fact, as then supposed, that it was not adapted for the operation of motors. This objection, or rather shortcoming, has now disappeared with many others of a like nature, but there is still one application in which the alternating, as such, can not be used, and that is, in the charging of storage batteries and electrolytic work generally. True, it was early suggested that by means of a revolving commutator the alternating current might be redirected and the object sought for thus attained; and our readers will also recall Mr. Tesla's more recent ingenious method of reaching the same end by various methods, all based on the principle of providing two paths for the alternating current, each of which allows the current of only one polarity to pass beyond it to the circuit. That the problem is still before the eyes of electrical inventors is shown by the neat device due to Messrs. Zipernowsky and Deri and illustrated on another page.

THE TESLA MOTOR IN MINING WORK.

THE alternating current system of electrical distribution has recently demonstrated its great usefulness on a new field by proving a wonderful success in mining work.

The Willock mine, belonging to the Monongahela Gas Coal Company and situated in the first pool of the Monongahela coal region, is now operated with a complete plant of this system. Alternating current motors are utilized as a source of power in the production of the coal, the working of the pump and also in the manipulation of an enormous ventilator which keeps a constant draught of pure air in the mine. In addition to that, the mine is also illuminated by the alternate current system.

Inasmuch as this is the first mine in the Pennsylvania coal region where the alternating current system is utilized very extensively, our correspondent made a visit to the mine in order to make a personal investigation of the success of the plant. He was very much aided in his efforts, by Mr. John Werner, the mill boss, who believes that electric mining has no greater prospect anywhere than just in the coal fields of Pennsylvania. The reasons for this are many. In the first place, coal mining in Pennsylvania was never such a poor trade as it is now; in fact, it is so bad that a native born American will have nothing more to do with the work. The result has been that the business has fallen into the hands of foreigners of the very lowest class, such as Hungarians, Poles and Italians. Then again, the price of coal has gone down to such an extent, induced of course by competition, that it is impossible to get any intelligent men who will do the work for the small wages a miner is able to make. This condition of affairs caused the coal operators to hail the advent of electricity as a coal miner with great delight, and it will probably not be very long before every mine in the country will be operated by electricity.

The advantages afforded by electricity in the operation of a mine are so manifold that its use is bound to become general. For instance, where a coal digger was able to earn on the average $2.25 per day, the machine miner makes $3. This is possible, because, while the operator pays the miner less for the production of each ton of coal, the man can produce so much more with the aid of his machine that he can make better wages now and the work is less laborious. The operator pays the coal digger 79 cents per ton of coal, but the production of each ton with the aid of electricity costs him only 49 cents, so that there is a pure gain for the operator of 30 cents for each ton.

The plant consists of a thirty h. p. Tesla quarter-phase generator of a capacity sufficient to carry seven motors when cutting coal, at the limit of the capacity of the coal company. The generator is self-excting, self-regulating, and so wound that as the load increases, the E.M.F. rises. By the aid of a hand rheostat, the adjustments can be so made that the falling off in the speed of the engine and the drop in the line may be compensated for, so that at the motors a very close approximation to constant E.M.F. is obtained. After the hand rheostat is once adjusted, it is unnecessary to make further adjustments, for the self-regulating devices are automatic. Three wires are carried from the collector at the end of the generator shaft to the switch board and pass through the switch board instruments and main line switches directly into the mine. On the switch board is a direct reading voltmeter and an ammeter. The E.M.F. at the motor is 300 volts in this installation. Where the distances becomes very great, a higher E.M.F. may, of course, be used.

The mine is wired with high class rubber-covered wire, and the insulation of each wire is practically continuous from the point where the wire leaves the main switch in the power house until it reaches the end of the circuit. At the entrance of each room, and also at convenient points throughout the mine, switches are located and safety catches inserted. This insures safety from short-circuiting and also allows any portion of the circuit to be cut off from the generator without interfering with the work in other parts of the mine. From the switch in the room to the coal cutting machine the current is carried by a three-wire cable. This cable is highly insulated and covered with a protecting braid, and though it is frequently allowed to lie on a damp floor and even in pools of water,

THE TESLA MOTOR DRIVING A HERCULES MINING MACHINE.

no inconvenience is noticed arising from this usage. Owing to the simplicity of the alternate current motor it is necessary only to have a jaw switch at the motor with which the circuit can be opened and closed. No regulator of any kind is used, and the only auxiliary apparatus connected with the motor, with which the operator of the machine has anything to do, is the switch to turn the current on and off. The motor is completely covered and the chance of getting a shock through careless handling is nil. Our illustration shows the motor mounted on the drill.

The mine owners are well satisfied with the performance of the plant and the men bring out from 45 to 50 tons of lump coal with each machine per day.

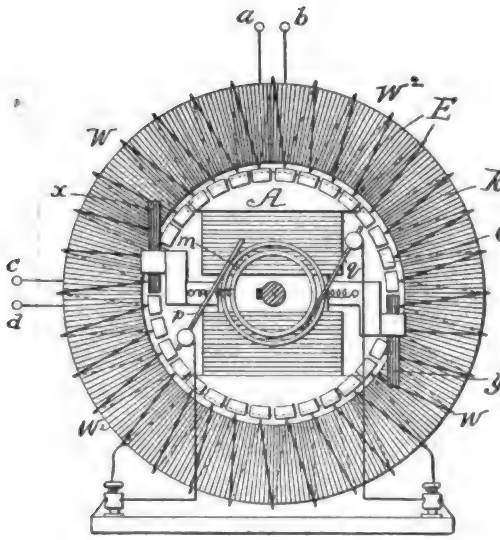
The coal mining machine used at this mine is the Hercules machine, and the entire electrical equipment was carried out by the Mill and Mine Electric Equipment Co., of Pittsburgh, Pa.

THE ZIPERNOWSKY-DERI CURRENT CONVERTER.

While the alternating current can now be applied directly to nearly all purposes of electric lighting, power transmission, etc., there are still cases in which the continuous current alone is applicable, such for instance as the charging of storage batteries and electrolytic purposes generally. To effect these objects, it is necessary to convert the alternating into a continuous current, and a neat method has recently been devised by Messrs. Zipernowsky and Deri, of Buda Pesth.

The apparatus consists essentially of an alternating motor combined with a Gramme machine in a very ingenious way.

The manner in which this is carried out is illustrated in the accompanying engraving. Here the ring magnet E is



The Zipernowsky-Deri Current Converter.

is wound with two pairs of coils W and W², with terminals *a b* and *c d*. Through these terminals the alternating currents are supplied to the two pairs of coils, so that the current supplied to one coil lags behind the other a quarter of a wave-length. Besides these two pairs of coils there is wound upon the ring a third coil E, which is in the nature of a secondary coil, for the induced currents. Divisions of this secondary coil are connected up to corresponding sections of the fixed commutator C, after the manner of a Gramme ring, for the production of the continuous current.

Within the ring E is the iron armature A, keyed to the central shaft, so as to be free to rotate within the ring, and the armature also carries the pair of brushes *x y*, bearing upon the fixed commutator C and electrically connected to the two contact rings *m n* on the shaft. The iron armature will always seek to lie in the direction of the magnetic axis, and therefore will rotate synchronously with it. The brushes, being once for all placed on the neutral points and being rotated by the armature, will keep on the neutral points.

To make the apparatus start easily, the rotating iron armature is furnished with a coil closed upon itself, so that currents are induced in the coil in starting, increasing the torque between the armature and ring-magnet. As soon as synchronism is reached, these currents in the closed coil disappear.

It is evident that with the apparatus described, continuous currents may also be converted into alternating currents if the greatest part of the continuous current supplied be led through the contact-rings *m n*, and through the brushes, for instance, into the commutator, and so into the coils for continuous currents. A small part of the current is employed, however, to effect the magnetization of the armature. By that means the apparatus will rotate in the same manner as a continuous-current motor, and there will be produced in the coils for the alternating currents two alternating currents, the phases of which are relatively shifted by one-quarter of a wave-length, and which are led off from the terminals to be used as desired.

A PROOF OF MAXWELL'S THEORY OF RESIDUAL CHARGES.

BY H. MURAOKA.

According to Maxwell's theory no residual charge can appear in a perfectly homogeneous dielectric, whereas parallel layers of various dielectrics, each homogeneous in themselves, will give a residual charge, provided none of them is a perfect insulator. The first part of the theory has been already established by the researches of Rowland and Nichols, Hertz, Arons, and Dieterici. The author of this paper succeeded in proving the truth of the second part by Dieterici's method He superposed layers of two of the dielectrics, paraffin oil, petroleum, castor oil, oil of turpentine, xylol, paraffin and air, and with some exceptions found considerable residual charges. The exceptions occurred when two good insulators or two miscible fluids were chosen. When one dielectric is soluble in the other, as for instance paraffin in xylol, the residual charge disappears. Maxwell's view would lead one to expect a residual charge where the dielectric consists of microscopically minute particles of different substances. This, therefore, cannot be the nature of the solution.

THE LINEFF ELECTRIC TRAMWAY.

This system, which was illustrated in our issue of July 23, has just been favorably reported upon by Mr. Gisbert Kapp, who calls attention to the novelty of the double set of magnetic rails. He has tested the line by taking a steam roller over it, and then drenching it with water for 26 hours, after which no fall of insulation was found, the resistance being 3,400 ohms. Tests at different speeds showed that two feet of rail under the car at either end were out of circuit. The only criticism made in the report relates to the power required to propel the magnet. This amounts to only half a horse-power at seven miles an hour, and Mr. Kapp indicates means of reducing it.

THE RADIOMICROMETER.

In an interesting communication by Prof. C. V. Boys to the Royal Society on measurements of the heat of the moon and stars by means of his radiomicrometer, he gives an account of a test with a candle at 250.7 yards distance, which gave a deflection of 38mm. If ¼mm. be taken as the smallest deflection which can be observed with certainty, the instrument, as made and used by him, would show the heat of a candle at 1.71 miles distance, neglecting the absorption by the air.

ALTERNATING CURRENT CENTRAL STATION AT ROME.[1]

BY DR. J. A. FLEMING.

This has been characterized by Professor Forbes as "the finest example of an alternating current central station," and it well deserves this commendation.

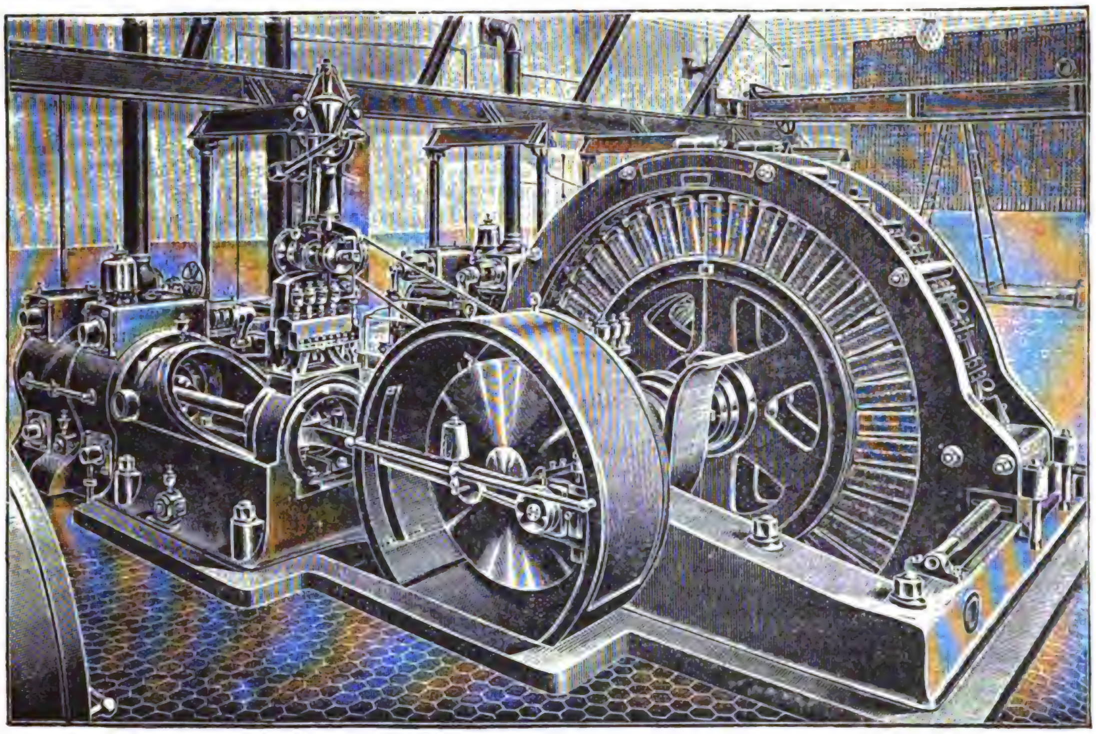
Since his account of it an addition of two 600 h. p. engines and dynamos has been made and the plant has at the present time a capacity for 24,000 sixteen c. p. lamps.

The electric lighting of Rome is carried out by the gas company, which has enlarged its operations and exists under the denomination of the Società Anglo-Romana per l'Illuminazione di Roma col Gas ed altri sistemi. The Directors of this Company were wise and far-seeing enough to recognize the necessity of dealing with the electric light either as an ally or as a rival, and in the spring of 1886 commenced operations for the supply from the gas works of the electric current by the Ganz alternating system. The gas works at Rome are in the Via dei Cerchi, near the Tiber, under the shadow of the Mount Palatine, and occupy a position in the region of old Rome, near the site of the ancient Circus Maximus; and in building the foundations of portions of the heavy dynamo machinery some of the old arches of the Circus were exposed.

The central station plant consists of two similar small alternators of a power of 80,000 watts giving a maximum current of 40 amperes at a pressure of 2000 volts, which are coupled direct to engines of 125 h. p., and of four large alternators of 320,000 watts, each giving a maximum current of 160 amperes at a pressure of 2,000 volts. The large dynamos are coupled direct to compound steam-engines working up to 600 h. p.

Commencing the description with the first two, or smaller machines, these were placed in position, and began to be used in the autumn of 1886. The engines are single-cylinder high-pressure engines by Gebrüder Sulzer, of Winterthur and Ludwigshafen. The speed is 250 revolutions per minute. Each horizontal engine is built on a common bed-plate with the dynamo, and the revolving field-magnet of the dynamo forms the flywheel of the engine. The engines can be worked up to 150 horse-power. There are 20 coils in the fixed armature, and 20 poles in the stellate field-magnet, and in the armature all the coils are joined in series, each giving 100 volts, or 2,000 in all. In the field-magnets the coils are arranged in two series of 10 coils each, joined in parallel. The alternations are 5,000 per minute, or about 42 complete periods per second. These dynamos are auto-excited by a rectified alternating current and commutator, taking current from the secondary circuit of a field transformer, of which the primary coils are in connection with the armature of the alternator.

The larger dynamos (placed in position and started in November, 1887) are separately-excited alternators, coupled direct to 500 horse-power compound engines by Van den Kirchoffe, of Ghent. These last have elaborate expansion valve gear of the Corliss type, and also centrifugal governors of the usual kind. The dynamo is placed between the high-pressure and low-pressure cylinder, so that the field-magnet is slung on the centre of the steel main shaft. The ring-shaped armature frame has massive projections or lugs on either side, supported by, and traversing in, guide bars like the bed of a lathe, and it can be traversed laterally by a screw, so as to move it off from and expose the field-magnet revolving in the interior. The interior diameter of the armature ring frame is about nine feet and a half, and the over-all diameter of the stellate field-magnet rather more than nine feet. In the large dynamos, Nos. 3 and 4, the field-magnets have solid cast-iron cores and wrought-iron polar caps or projections; and these magnets, 40 in number, are placed round the periphery of an iron wheel keyed on the main shaft. The armature cores are built up of plates of thin sheet iron with interposed paper. The two smaller dynamos also have armatures built in this way, with divided iron cores and solid cast-iron field cores with sufficient pole pieces. Their armatures are composed of 40 coils, each one developing a potential of 50 volts, and these bobbins are joined in series. In the field-magnet the 40 coils are joined up so as to make two series of 20 each, which work in parallel. The engine makes 125 revolutions per minute, producing thus a current of 5,000 alternations per minute, or 42 complete periods per second. The armature coils will carry safely 200 amperes, but their normal load is 160. The copper wire on the armature and magnet coils is 6mm.—about one-fourth inch—in diameter.



Ganz Alternating Current Station at Rome, Italy.

1. Abstract from the London *Electrician*.

The last two large machines, No. 5 and No. 6, are generally very similar to No. 3 and No. 4. They are driven direct by compound 500 horse-power engines by the Erster Brünner Maschinen Fabrik of Austria; and in this case also the dynamo field-magnet is slung as a flywheel in between the high-pressure and low-pressure cylinder. In order to give space for the stellate magnet and annular armature frame, a pit is formed between the high-pressure and low-pressure part of the engine. These last engines have governors of the type employed in the well-known Armington and Sims engine, in which the lead of the single eccentric is shifted and controlled by the outward movement of two massive weights contained in the interior of a pulley-shaped governor wheel. This governor is, for convenience, placed on the outside end of the main shaft of the engine. The general appearance of these last two 500 horse-power dynamos is shown in the illustration. These engines have been found to do their work remarkably well and to govern steadily.

In these last dynamos, No. 5 and No. 6, the cores of the field-magnets, as well as the armature cores, are built up of laminated iron. The bobbins of the field-magnets are formed of rectangular split zinc frames, about 15 in. high and 20 in. wide. They are wound over with the insulated wire, but more wire is placed at the bottom of the frame than at the top, and the finished bobbins have a slight taper from about 8 inch to 6½ inch in end width. The armature bobbins are shallow rectangular bobbins, wound on vulcanized fibre frames about 19 inches long and 10 inches wide and 2 inches deep. Each bobbin has on it about 30 turns of highly insulated copper wire, about 6 mm. or ¼ inch in diameter. The armature coils when slipped on to the laminated iron cores are kept in position by bobbin holders of bronze, which form a kind of skeleton frame clamped on the end. The more massive electro-magnet bobbins are secured by a similar bobbin holder, and by a bolt fastening it which traverses the whole width of the laminated core. The terminals of the field-magnet circuit are led to two insulated brass pulleys, deeply grooved, which are secured on the shaft. Over these are slung flexible copper stranded cables, one end of which carries a pendant weight, and the other end of which is in connection with the exciter circuit. This affords an excellent and yet a perfectly flexible contact surface, for the exciter current to enter and leave the alternator field-magnets. The mechanical performance of these latest machines is very excellent; the dynamos run very smoothly and quietly, and give no trouble by any heating or insulation defects.

To excite these four large dynamos, there are three exciters driven direct by Westinghouse engines of 50 horse-power each, made by Alley and Maclellan. The exciting dynamos are by Ganz and Co., and are four-pole continuous-current machines, which, at a speed of 375 revolutions per minute, give a current of 150 amperes and pressure of 180 volts.

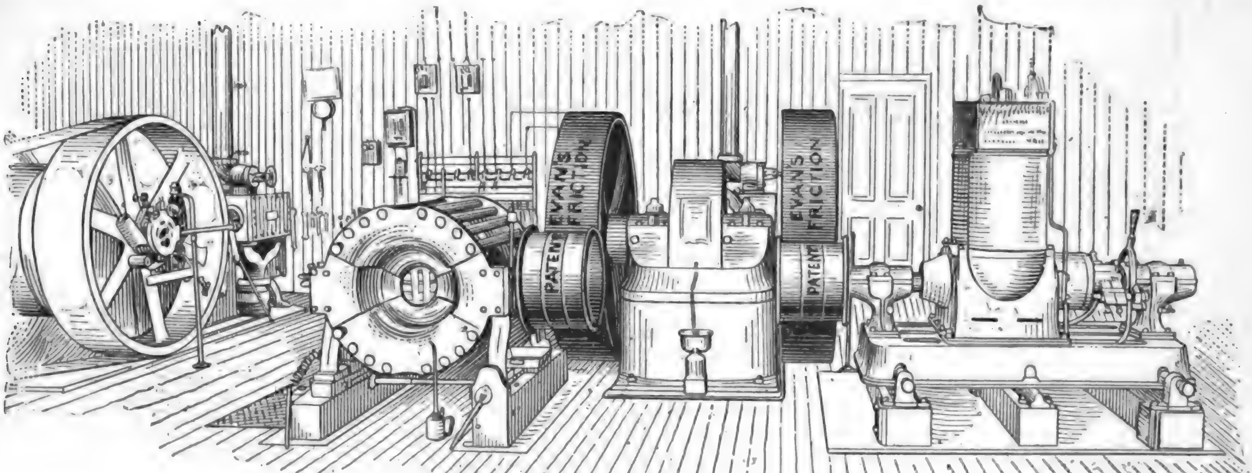
Since 75 amperes is a sufficient exciting current for each of the large dynamos, one exciter can excite two of the large dynamos, and hence there is always one exciter in reserve. At full load the power absorbed in exciting is said to be 3½ per cent. of total absorbed power. The steam is provided from a plant of fourteen Babcock and Wilcox tubular boilers, each of 160 nominal horse-power. Coke is burnt in the furnaces. Four steam pumps, in addition to the usual injectors, supply water to the boilers. The total boiler horse-power is 2,240 h. p. The steam pressure is 120lbs.

There are, therefore, in this station three pairs of machines, each pair consisting of two similar independently driven dynamos, but all yielding a current at the same electromotive force, and having the same frequency of alternation.

EVANS FRICTION CONE DRIVING, AT HUTCHINSON, KANSAS.

We have already described in these columns the interesting method of driving dynamos employed by the Evans Friction Cone Company, of Boston, and have noted a number of plants in the East in which the system has been employed with success. We now illustrate an installation on the same system in the electric light station at Hutchinson, Kan.

The dynamo at the left is a Thomson-Houston "M. D." machine, with a capacity of 50 full arc lamps, and the machine is fully loaded. The Edison machine is a No. 16, of a capacity of 720 incandescent lamps. Both machines are driven from the fly-wheel of an Armington and Sims engine. This plant has been running constantly since January, 1890, and is giving entire satisfaction in every respect. The saving in room effected in this plant, as well as the economy in belting, the smooth running, etc., have attracted considerable attention among Western electric light men.



Evans Friction Cone Driving, Hutchinson, Kan.

ELECTRIC ETCHING.

The *Papier Zeitung*, of Berlin announces that an important discovery has just been made in etching, and especially in photogravure. As usual, the drawing is traced on a plate of zinc, either by an artist or by photography, with any suitable etching ground. This plate, backed with asphaltum, is laid in a bath of dilute acid. It is then put in circuit with a dynamo, the other pole being merely placed in the acid. When a current is allowed to pass, the acid attacks the metal with surprising rapidity. A few minutes suffice to bite the plate, and the depth of the etching can be easily controlled. The action is probably due to the depolarization of the surface of the metal, which in the ordinary method of etching becomes covered with a film of hydrogen, or, at all events, with a number of minute bubbles, which make the biting irregular unless the plate is incessantly rocked and brushed.

THE DEY SERIES HIGH POTENTIAL STORAGE BATTERY.

In our issue of last week we drew attention in a short note to the appearance of a so-called "series" storage battery which had been brought out in England and was designed more particularly for small work, such as carriage lighting, etc. In this battery, it will be remembered, the individual plates were positive on one side and negative on the other, so that the potential of the cell was equal to 2 volts for every plate.

We have now had our attention called to a similar type of cell which has been in operation in this city for some time past, and on which the patents were granted over a year ago. It is the invention of Mr. Harry E. Dey, of this city.

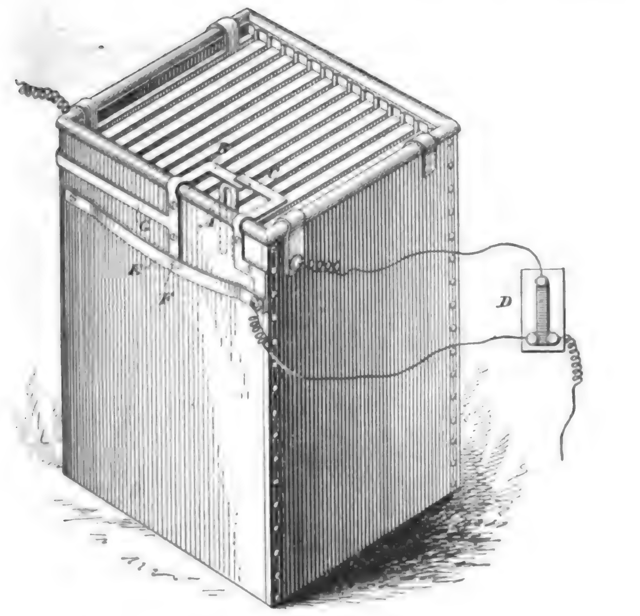


Fig. 1.—The Dey "Series" High Potential Storage Battery.

Beginning with the outside case, Mr. Dey uses hard rubber made from sheets that are screwed together. This is lined with a soft rubber box having cleats or ribs running down the sides and across the bottom. The lead plates, which have a raised rim, slide down the grooves formed by these ribs, and when the side is screwed on it forms water tight joints between the ribs and plates. On the bottom the ribs are about an inch deep and run up to a point forming a tongue between the plates, thus keeping any active material which may fall from short-circuiting the plates.

The plates are 9x15 inches, and the main body is $\frac{7}{16}$ inch thick, the rim being raised above this $\frac{1}{8}$ inch, and they are placed $\frac{3}{8}$ inches apart. A complete cell, as shown in Fig. 1, contains eleven whole plates and two half or end plates, and weighs 210 pounds; it has a normal output of ninety-four ampere hours, and an E. M. F. of 24 volts, or 2276 watt hours, which is equivalent to over three horse-power hours. Mr. Dey claims that he will double this output with the same weight with a new plate that he is experimenting on.

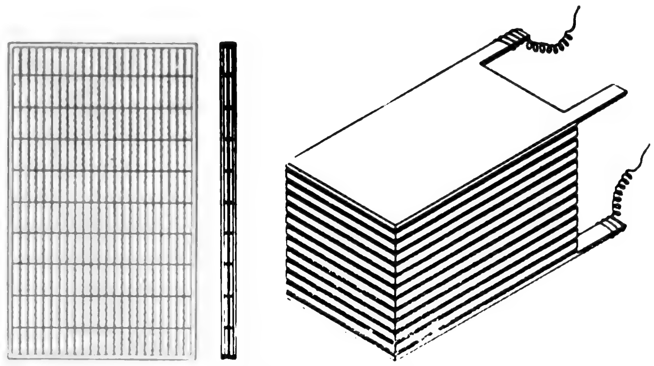
The plates at present in use are made grid fashion, with a web or partition down the centre and projecting half an inch above the active material to keep the acid separated, as shown in Figs. 2 and 3. The ribs of the plate form rectangles $\frac{3}{8}$x$1\frac{1}{2}$ inches and are $\frac{3}{16}$ inch deep on each side of the web. To keep the active material from falling out, a round-pointed knife blade is drawn across at every quarter inch, which forms hooks reaching out over the active material, making it impossible for it to fall out.

The active material is applied in the form of a dry powder, red lead being placed on the positive side and litharge on the negative. It is pressed in just hard enough to bear light handling, and is then piled up with sheets of felt saturated with dilute acid, as shown in Fig. 4. Wires are connected to the upper and lower plates and a strong current passed through, which immediately forms them almost as fast as they moisten, positive on one side and negative on the other, in the fashion of a voltaic pile. Contrary to plates formed in a jar, they form on the surface first. The pressure of the plates piled on top of each other keeps the material very compact while forming.

Mr. Dey has constructed a cell that had two of its plates made according to the "paste" method and the rest with dry powder, and as the plates were all in series they all received the same current and usage. This cell accidentally had a fall which broke the case into fragments but did not injure the plates. The pasted ones were found to have scaled badly, and were also badly sulphated and buckled, while those formed with dry powder were in as good condition as when placed in the case. A comparison of the two convinced Mr. Dey that dry powder was far superior to the paste.

One advantage of this form of cell, as pointed out by Mr. Dey, is that when they do buckle (which occurs rarely) they all buckle in one direction (positive side out), and fit into one another like saucers. Another advantage is that the plates are not in any way connected, and a defective one can very easily be removed at any time, and a perfect one substituted; besides, a short-circuit short-circuits one plate only, instead of a whole cell, as is the case with the usual type of storage battery.

In connection with the new cell Mr. Dey also employs some very ingenious cut-outs. One for cutting out the battery when fully charged is made with a light inverted U-shaped tube, A, shown in Fig. 1, which is filled with acid and hung on the plate into the solution. A spring, B, projects over this, and a strip of metal, C, over the spring, one being connected to one pole, the other to any alarm or cut-out device, the cut-out being also connected to the other pole. The gas arising from a fully charged cell rises into the tube, displaces the acid and raises the tube against the spring. The latter thus comes in contact with the strip, C, making a contact that operates the cut-out.



Figs. 2, 3 and 4.—The Dey "Series" Storage Battery.

Another cut-out is used in case a battery is being charged too fast and heats. This consists of a strip of metal, E, that extends across the box and is fastened to it at each end and bows outwards. Under the bowed part is a pin, F, which is normally out of contact with the strip, G, but the expansion of the hard rubber, caused by the heat, draws the strip down in contact with it; and as the pin and strip are connected to the poles, as in the preceding case, it acts likewise to cut out the cell. In practice Mr. Dey combines the two cut-outs in one.

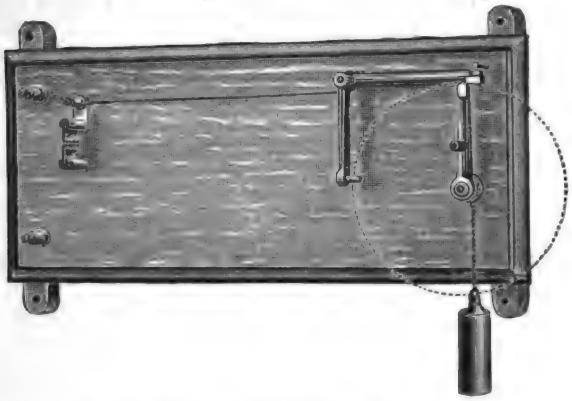
The Sawyer-Man Electric Co. have had fifty of these cells made. They use eight of them in their Boston office, and the remainder at their office and factory in this city. They have two series of six cells for their photometer room, giving an electromotive force of 144 volts. The rest are connected up in series of three, each series giving 72 volts for their lighting circuit. Mr. Dey does not pro-

pose to limit the use of his cells to lighting carriages and other small work. He claims that they will do the work of any other battery, besides being applicable in many fields that other batteries cannot enter. Thus an arc lamp works nicely on two cells. Again, with smooth streets, we would probably soon see all vehicles run by electricity, as with these batteries a carriage can be run with two or three cells; all that is necessary are numerous sub-stations where the batteries may be charged or left while not in use, in the same manner as a horse would be stabled.

BAIN'S HOT WIRE LIGHTNING ARRESTER.

A LIGHTNING arrester, to be practical, should evidently protect the circuits when they are idle with as great fidelity as when the dynamos are in operation. It should ordinarily be so constructed as to have no self-induction, and an absolute break of sufficient distance to interpose enough resistance to open the arc should be made with every flash of lightning that comes in on the lines. These breaks should be absolute and not depend upon any equilibrium mechanism for the length of break; they should be automatic, so as to take care of a number of flashes in rapid succession without any manual attention, and a further requirement is that they should protect circuits used for alternating currents with an equal degree of promptness and certainty as circuits which are used for straight currents.

A device fulfilling all these conditions has been recently designed and patented by Mr. Forée Bain, of Chicago. The accompanying engraving shows how the circuit to



BAIN'S HOT WIRE LIGHTNING ARRESTER.

ground is absolutely opened through the expansion of a small iron wire, due to the passage of the flash or the dynamo current. The iron wire forms a part of the circuit to ground, and as the lightning leaves the line at the comb it passes over this wire, which is expanded. A spring acting against the wire causes the trigger to unlatch the metallic winch, which forms part of the circuit, and to this winch is attached a string, wound round a drum, which is a part of the winch. To the string is hung a small weight, which causes the winch to revolve when released, so that when the wire has been expanded by the passage of current the winch makes three-quarters of a revolution and stops against an insulated stud on the arm, part of which forms the trigger. It then rests against this insulated stud, leaving the circuit to ground open until the wire contracts sufficiently to release it from the stud, when it completes the revolution and once more rests against the trigger and is ready for another flash to repeat the operation.

This arrester is said to be thoroughly reliable, and may be placed on either side of converters on alternating circuits, or in dynamo rooms on either alternating or continuous current circuits. In actual operation the wire does not get warm enough for the heat to be detected by touch.

The Central Electric Co., of Chicago, have taken the agency for Mr. Bain's arrester.

AN ALL-COPPER RAIL BOND.

IN electric railways with overhead wires, the resistance of the ground return, and the consequent loss of energy, will depend largely on the connection between adjoining rails. The various forms of rail-bonds now in use are made wholly, or in part, of iron and still leave better conductivity to be desired. To fill this want, The Great Western Electric Supply Co. are making a rail-bond entirely of copper. The cut shows the two end pieces and

AN ALL-COPPER RAIL BOND.

part of the connecting wire full size. The taper pieces fit into holes drilled in the rails, and when upset in place they form a good metallic connection. The connecting piece can be made of any desired diameter and length, to suit the different circumstances, and can be bent to meet any unusual change. This rail bond does away with the brass and iron pieces formerly used, and should give a joint of practically no resistance.

IMPORTANT WORK OF THE N. Y. STATE RAILROAD COMMISSION.

The State Railroad Commission has approved the form of grooved rail which the Third avenue road, in New York City, will lay down when it changes its motive power from horses. The company, in its application, presented a form of grooved rail which it asked the board to approve in case it did not favor the tram rail, which was also presented for approval at the same time and was desired by the road. The rail approved by the board is a cross section of rail not less than seven inches deep, the head of which is to be not less than two inches. The grooves shall not exceed one and one-quarter inches in width at the top and three-eighths of an inch at the bottom, with a depth of one inch.

The thickness of the metal forming the inner side of the rail shall not be less than five-eighths of an inch at the surface and the upper surface of the same shall not be more that five-sixteenths of an inch lower than the head of the rail bed, and the general construction of the pavement is to be laid in conformity with the requirements of the Commissioner of Public Works. The form of grooved rail suggested by the company and approved by the board does not meet the ideal requirements of street surface rail. In the opinion of the board it is so much better, however, than tram rail that the board concluded to approve it, particularly in view of the fact that it is in practical successful operation in other large cities.

The board favored a simple groove not exceeding seven-eighths of an inch opening at the top and of the same depth, with the surface of the rail on each side of the groove flush with the pavement. The strenuous contention, however, upon the part of railroad companies that a wider groove at the top and a slight depression of five-sixteenths of an inch of the inner surface would be absolutely necessary to permit dirt and ice to be worked out of the groove, led the board to approve of the cross section as submitted by the railroad company.

The commission also approved the application of the Coney Island and Brooklyn Railroad for permission to change its motive power from horses to electricity upon that portion of its road upon Sea Breeze avenue from East Fifth street to West Fifth street, on condition that the rate of speed of its cars shall not exceed that to be determined by the Highway Commissioners of the Town of Gravesend, and that no car shall be operated with less than two men in charge.

MOTORS VS. STEAM ENGINES IN CHICAGO.

The last piece of steam propelled machinery has now been dispensed with at the Columbia Theatre. The fires have been drawn from the furnaces and no more complaints can be brought against this house for burning soft coal. Electric motors now furnish all the required power, and the change is one which is thoroughly appreciated by every one concerned.

ELECTRIC LAUNCHES.

BY FRED. RECKENZAUN.

Whenever we allow ourselves to indulge in a retrospect on historical events, be it for our own enlightenment or for the purpose of gathering a suitable assortment of specific references with which to introduce the discussion of a certain subject, we are apt to take special cognizance of such facts and features as reflect their characteristics strongest upon the point of view chosen.

In discussing the subject to which this article is devoted, we do not deal with a new invention, but with an aggregate of inventions, which individually have been, and possibly will be, from time to time, exchanged for others of a different class. Before entering upon an analysis of the electric launch of the present day, we will, therefore, briefly review the principal features of its history.

The idea of applying electricity to the propulsion of vessels is as old as that involving the employment of the same agent for traction purposes. Indeed, electrical navigation was an experimental fact, not a mere idea, over half a century ago. Being first conceived and demonstrated by Prof. Jacobi in Russia, during 1838, his fascinating achievement was followed up in England by Robert Hunt early in the fifties; by G. E. Dering in the year 1856, and in France by Count de Moulins in 1866. In all these experiments electro-magnetic motors and primary batteries of various descriptions were employed to actuate the propeller. The results obtained, although demonstrating the possibility of electrical navigation, failed, however, to prove its commercial feasibility. This was due, not to a lack of versatility on the part of the projectors in effecting suitable combinations of known devices, but to the very absence of such of the latter as were essential to success. Not only were the batteries themselves cumbersome, bulky, of comparatively small capacity, and expensive in operation, but the motors added to the disadvantage by their low efficiency.

With the advent of the dynamo electric machine—that great helpmate to which so many dormant inventions owed their revival—the subject of electric boats gained in feasibility. The storage battery, which was of little use without an economical generator, came forward in commercial form, while the reversibility of the dynamo itself was productive of a highly efficient motor. With the storage battery in place of the primary battery and a new type of electric motor in place of the old ones, the electric launch entered upon a new era.

Trouvé availed himself of these improvements in 1881 in Paris, but also employed a primary battery of his own; his experiments were the first with storage batteries and the last notable ones on record with primary batteries. In 1882 the Electrical Power Storage Company, of London, brought out the launch "Electricity," designed by Anthony Reckenzaun. During the years following, electric launch building gradually developed into a distinct branch of electrical industry, especially in England, where the advantages of this class of craft for pleasure purposes have met with such increasing appreciation and favor as to cause the establishment of a series of charging stations along the Thames river (by Messrs. Immisch & Co.), where a whole fleet is in use now, while a regular passenger service by electric boats has quite recently also been introduced at Edinburgh, Scotland.

We will now proceed to the main object of this article —the discussion, from an electrical point of view, of the principal details of construction and equipment of a modern electric launch.

THE HULL.

The hull of an electric launch need not materially differ from that of a steam or naphtha launch. The shipbuilder's work remains the same, only the interior or joiner's work requiring adaptation to the different nature of the equipment. By this is not meant, however, that any sort of hull will give satisfaction. Before we have it built it is well to know what we are going to put into it—the kind and size of motor and the number and size of battery cells. Space is limited on all sides, and the features of the hull, motor and battery should be carefully considered in their mutual relations.

After we have roughly modeled the lines, either in accordance with the shipbuilder's practice, or to suit a special fancy, it will be of advantage to lay down upon paper the cross sections, taken at suitable distances apart from bow to stern, a longitudinal section and a plan. We have but a single straight line in an ordinary launch hull, and that is the keel. The rest are all curves of various character. These curves and the dimensions of the motive power outfit should mutually agree, or else they are likely to prove awkward when the apparatus is being put in place, and a sacrifice of some kind would be the probable consequence, which, perhaps, a very slight deviation from the lines of the model might have avoided. The hull should be substantial throughout to withstand the strain from the weight of battery and motor when in rough water. The joiner's work will include a battery receptacle or receptacles of the required dimensions. A trough placed directly over and along the keelson, with the seats arranged on top of it, has the advantage of giving the boat maximum stability, since the centre of gravity will then fall near the keel, below the water line. The passengers sitting back to back in two rows along the centre, will add to this advantage, while they at the same time may have an unobstructed view in front of them. Another method consists in placing the battery in a similar trough, laying the floor over it, and arranging the seats above this floor along the sides or across the hull. Access to the battery can be obtained in the first instance by removing the top of the seats, and in the latter through trap doors in the floor. Again, another way of distributing the cells consists in arranging the battery receptacles along the sides of the hull, with seats on top of them. A combination of the above methods may be effected to suit preferences. It is well to remember, however, that one of the advantages of the electric launch is that its stability may be made to exceed that of any other launch by a judicious distribution of the weight of the propelling apparatus.

As to the material of the hull, wood is preferable to steel or iron if it is considered that acid is to be carried on board, although by a suitable construction of the cells and receptacles leakage or spilling can be prevented under ordinary conditions.

THE MOTOR.

A good launch motor embodies high efficiency, with special compactness, low speed and reasonably light weight. These qualities are not easily to be found combined to the desired extent either in stationary or car motors.

It is usually desirable to put as large a power outfit into a boat as can be conveniently placed there and looked after, and since the battery requires the largest amount of space, the obviously most suitable place for the motor is in the stern, as far back as possible. The shape of this space then will guide us in the selection or construction of the motor. The cross section in an ordinary launch hull resembles the shape of the lower part of a heart, diminishing in width toward the sternpost. The available base area for the motor being triangular, the base must be narrow. With an armature of about double the length of its diameter and the field magnets crowded around it to suit the lines of the hull, we have a motor that can be placed without unnecessarily encroaching upon space desirable for batteries or passengers. A low armature speed (say 500 to 800 revolutions per minute) will admit of coupling the motor shaft directly on to the screw shaft without necessitating excessive fineness of pitch in the screw. We have here the ideal method of transmission. There is no lateral strain on the motor bearings, while the thrust bearing, interposed be-

tween the motor and the screw, takes up the longitudinal strain.

The conditions of load in a launch motor are analogous in the main to those of a fan motor, but more particularly to those that would be encountered in an air ship or flying machine, the following characteristics being observed:

The load consists in the resistance offered by the water to the motion of the screw. The movement of the latter is independent of its support—the boat in the present case—and its effect will be either to set in motion the medium (water) in which it moves, if the support is fixed, or to propel the latter if it is free, in consequence of the inertia of the medium. Hence the force required to start a boat is merely that required to overcome the inertia of the body of water affected by the screw proper and is independent of the inertia of the boat. The motion, being first imparted to the water, is gradually transferred from the latter to the boat, until a point of equilibrium is reached, determined by the resistance encountered. It will be seen from this that even if we throw the full load upon the motor at once (as is usually done), the difference between the starting effort and that required to maintain the final speed of the boat is so small as to be entirely negligible in the determination of the capacity of the motor. Speed once being reached, the load will remain constant on a straight run, while it will slightly increase on turning the vessel about, until a straight course is resumed. In running against a current, the load of the motor is smaller than in still water, while it is greater on running with the current. Under the conditions ordinarily met with, this difference is, however, but slight. Automatic governing devices are obviously not required; unless we were to consider an equipment for a large seagoing vessel. If it is desired to get two or more different rates of speed, the battery may be split up into a corresponding number of sections, and by means of a special switch connected in series or parallel. As to the winding of the field magnets, plain series winding is the simplest and the least liable to give trouble. The conditions enumerated above necessitate no other. The brushes should admit of reversing the direction of the armature movement, but their "lead" is best adjusted for forward motion of the boat, unless a double set of brushes is employed, with reversing lever to engage one or the other as required. A suitable switch inserted between motor and battery serves for starting, stopping and reversing the motor.

THE BATTERY.

As previously remarked, the storage battery, on account of its superior fitness, is universally employed in connection with electric launches at present. Without entering upon the details of its construction, we will consider the features to be dealt with in its application. The first question confronting us is that of bulk and weight. The manner of disposing of the battery has already been touched upon in considering the hull. Being composed of a number of small units, there need be no difficulty in distributing it. An ordinary launch hull can well carry all the *weight* corresponding to the *bulk* of battery which can conveniently be placed with due regard to accessibility. We will, for convenience, take into consideration a battery of a well-known type, designed for portable and locomotive purposes, occupying, per cell, 0.23 (solid) cubic foot of space (box, plates and all) and having a capacity of 150 ampere-hours, or about 290 watt-hours, at a discharge rate (normal) of 25 amperes or an average of about 48.32 watts; its weight being about 40 lbs. Reduced to unit cubic foot, we have: weight, about 175 lbs.; capacity, about 1260 watt-hours, with normal discharge rate of 210.1 watts per cubic foot. The displacement per cubic foot of battery will then be equivalent to ($\frac{175}{62.5}$=) 2.8 cubic feet of (pure) water; at this rate allowance for weight of battery must be made in determining the water line. With ordinary launch hulls, the average battery load that can be carried conveniently represents about one-third of the total actual displacement in tons, including passenger-load. Any smaller proportion may, of course, be applied, with correspondingly reduced results in capacity. The capacity of the battery and motor are considered mutually; for maximum effect the former guides the calculation. With the type of battery above assumed, if it is to be worked at "normal" rate, the capacity in electrical horse-power of the motor required will be equal to the number of cells multiplied by 0.0647, the working rate in elec. h p. per cell, or to the number of cubic feet of battery multiplied by 0.2816, the corresponding constant per cubic foot. For a rough preliminary calculation, on the basis that the weight of battery represents one-third of the total weight, we have,

$$\text{Capacity} = \frac{D}{3} \times 3.604 \text{ elec. h. p.}$$

where D=total displacement (weight) in tons and 3.604 the working rate of battery in elec. h. p. per ton (12.8 cub. ft). The duration, T, of the run in hours for one charge of battery will be:

$T = \frac{C}{R}$ hours, C denoting capacity of battery in watt hours and R denoting rate of delivery in watts.

Since the power required to propel a vessel varies as the cube of the speed, and since the duration of the run varies inversely as the power (rate of delivery), it follows that the *mileage* covered by one charge of battery will vary inversely as the *square* of the *speed*. In practice, due allowance is to be made for the characteristics of the motor and for a falling off in the total out-put of the battery when pushed to a high rate of delivery. Where a maximum of speed is to be effected, the battery should have a maximum of active surface and a minimum of internal resistance, to facilitate a heavy discharge without an excessive drop of potential. Special care should be taken to render the cells acid tight, by the use of suitable covers, etc. Spilling may also be avoided by preparing the electrolyte in a suitable manner. The jelly electrolyte invented by Dr. P. Schoop offers in this respect a remarkable advantage. It is also advisable to line the battery receptacle with some acid-proof material, preferably an insulator, and to provide a bed for the cells to stand on containing a substance capable of absorbing and neutralizing acid. All wires or cables employed about the boat should have a good acid and salt-waterproof insulation.

CHARGING FACILITIES.

These, or rather their absence, are a practical hindrance to a rapid introduction of electric launches. As in the early days of steam navigation, coaling stations were scarce and even wood was not everywhere available, there now exists a similar lack of suitable bases of supply for electric boats. Moreover, the supply of energy for the latter does not consist in solid matter kept in stock at a convenient place, but in a live current, to be produced on the spot at the time required, by means of comparatively complicated and expensive apparatus. It is at *this* point where compensation is exacted for the numerous advantages of the electric launch; but it is also at *this* point where the real labor attached to its operation, and where all the features of "nuisance," which are unavoidable with steam and naphtha boats, are located and concentrated. The charging plant consists of a power plant, dynamo and accessories of a capacity corresponding to that of the boat outfit. Where a continuous current incandescent lighting plant exists, current may be derived therefrom for charging purposes; suitable arrangements must, of course, be made in such cases for the proper application of the current, the E. M. F. of which may not always correspond with that of the battery. Supposing we have a launch containing 40 storage battery cells of the capacity above

assumed (150 ampere hours) and we have a 110-volt current for charging. The difference of potential required at battery terminals (cells in series) would then be $40 \times 2 = 80$ volts at the start and about $40 \times 2.5 = 100$ volts at the finish —if a constant current, 25 amperes in this case, is to be maintained. To reduce the initial E. M. F. of the circuit we must then introduce a resistance, R, of

$$R = \frac{110-80}{25} = 1.2 \text{ ohm}$$

at the start and gradually reduce the same as charging goes on to the final minimum of (approximately)

$$R = \frac{110-100}{25} = 0.4 \text{ ohm.}$$

Or, we may apply a constant E. M. F. of about 90 volts, (2.25 volts per cell) by inserting a constant resistance, R, of

$$R = \frac{110-90}{25} = 0.8 \text{ ohm,}$$

in which case we will receive a heavier current at the start, reducing itself (in consequence of the increasing counter E. M. F. of the battery) gradually to a minimum at the end, the average being the same as in the other case. The latter method may be preferable; the current will decrease in proportion to the facility with which the gases can be absorbed by the plates, while the results in time and efficiency remain practically the same and constant attention is rendered unnecessary. If a boat is to be charged, the battery of which, connected in series, requires a higher E. M. F. than that available, we merely need to split it up into two or more equal series to get within the required limit and then charge these in parallel with a proportional current, adjusted as above.

Storage batteries, suitable for launch purposes, are, as a rule, capable of receiving their charge at a higher rate and in less time than the employment of most arc light currents would involve; this is one reason why incandescent light currents (continuous, low tension) are preferable. But arc light plants are the ones most frequently met with and may often be the only source available. It should be remembered, however, that with a high tension current (say, 1,000 volts and over) an electric launch, floating in water, would not unlikely prove an inducement to "grounding."

The battery may, of course, be charged either on the boat or may be removed for that purpose. While the former method is ordinarily practised, it is obvious that in order to avoid delay, a freshly charged battery may be substituted for the exhausted one. With suitable facilities for handling the batteries, such as a hoisting crane, or equivalent device for lifting and lowering the cells into and out of the boat, tables to receive the cells for charging, suitable cell crates with connections and lifting attachments, etc., the work of exchanging the batteries could be effected promptly and efficiently for a whole fleet engaged in continuous traffic.

OPERATION.

The operation of an electric launch is the ideal of ease and simplicity. It consists, practically, of turning a switch and—letting her go. The pilot can act at the same time as engineer, for he can start, stop or reverse as easily as he may give a signal for that purpose, and need not wait for a response. Somebody, on noticing the incomparable facility with which an electric launch can be operated, suggested it was a veritable "buggy on the water." It certainly involves none of the jarring which inevitably accompanies a buggy-ride on land, and there is no need for "cheering up" or "urging" the animal. Not one of the smallest advantages is the fact that there is no danger of explosion. The most reckless handling of the propelling apparatus would entail nothing worse than its disablement, and as to danger from shock, it is unnecessary to explain its absence here. The run may be continuous or interrupted; a landing may be effected and the boat left without attendance for any desired length of time, and the journey resumed at a moment's notice. Knowing the number of miles or hours the boat can run with one charge, the man in charge will be guided thereby, as is the engineer of a steam launch by his pile of coal, and probably more definitely. The disagreeable features of steam and naphtha launches (aside from their danger of explosion), such as smoke, smell, soot, ashes, dirt, grease, heat, noise and the jerking caused by the reciprocating motion of the engine, are totally absent in the electric launch. The propelling machinery has substantially but one moving part and the motion of that is rotary, insuring smoothness, quietude and ease, and involving but a minimum of wear, while the liability to a breakdown is very remote. There is no necessity for the grimy man with dirty overalls—his place is on shore, at the charging station. The battery, besides doing its regular duty in operating the motor, can, of course, be employed at night to furnish current for interior illumination, side and signal lights, head light—a search light, if you please—or for submarine illumination.

REMARKS ON COST.

It is not the purpose of this paragraph to enumerate price lists of various sizes and sorts of hulls, batteries, motors and other paraphernalia; nor to juggle with figures in such a manner as would make it appear that among its rivals the electric launch is the cheapest at all events. On the contrary, as conspicuously as its advantages have been pointed out, be it admitted, that for same size and power, its first cost is usually greater than that of other craft. A storage battery and electric motor cannot be made or purchased at the price of an ordinary steam or naphtha engine of same power. The man who turns up the day after he has had an extended struggle in his sail boat against wind and tide on his homeward journey, thinking he may get an electric propelling outfit for his boat at about the price a new set of sails would cost him, gets disappointed. And so does he (motor manufacturers know the type) who imagines that an electric motor is all he needs to make a propeller out of his rowboat.

The cost of charging facilities—where such are not already on hand—is the weak point in the matter. It about equals that of the launch proper. Of course such a plant could be made to earn an existence by serving as an electric light plant at the same time, and thereby reduce the expense chargeable to the boat to a very reasonable item. But to get the two birds together is more difficult than to kill them. Where a fleet of electric launches is operated, however, the pro rata cost of plant and expense of operation can be brought within very reasonable limits. Instead of having an engineer for each boat (as in the steam launch), one station engineer can render equivalent service for a number of boats. The fuel item for one station engine need not exceed, and may be even smaller than, the aggregate consumption of several small engines (on steam launches), even allowing for the loss in conversion. The actual running expense would thus compare favorably with that of steam launches. There is another feature which should not be overlooked. In an electric boat, as pointed out before, the propelling apparatus occupies space which would be of little or no use for passengers, while in steam or naptha boats from one-third to one-half of the entire space is devoted to the machinery, and the best part of the boat at that, crowding out a proportional number of passengers. For a given number of passengers, therefore, the electric launch would be smaller, require less power, and consequently would cost less to run. Under such conditions, it would hold its own even on the point of expense, taken all in all.

In conclusion, a few suggestions as to

FUTURE ASPECTS.

While hitherto the electric launch has been confined mainly to a service of pleasure and recreation, it can-

not be doubted that where conditions are favorable, it would lend itself to regular passenger traffic with a satisfactory degree of efficiency, embodying, as it does, features well adapted to gain popularity. It would then bear a relation to large steamers, similar to that existing between the street car and the steam railroad, affording a means of communication over comparatively *short distances* in *small units*, at *frequent intervals*, taking up and landing passengers at points along the line; "feeding" railroad and through-steamer lines from points not touched by either; maintain traffic on small rivers and shallow waters not navigable by large vessels. Its readiness, whenever required at short notice, commends it to institutions and individuals located on shores or islands not otherwise supplied with convenient means of communication. It has been suggested as eminently adapted for harbor police service; its easy, quiet, and yet swift motion, the absence of visible or audible accompaniments to betray its approach, and the facility of suddenly flashing a dazzling beam of light when needed, would seem to render admirable assistance in the pursuance of river pirates or smugglers by night. Supplied with a force-pump, to be operated from the same source (battery) as its propeller, it would afford a safeguard as a floating fire engine for the water-front and vessels lying in the harbor, ever ready for immediate use, without the constant attention and maintenance expense inevitable with steam fire-boats. That the electric launch may find a field in the navy is indicated by the fact that the Italian government has attached one to a man-of-war. Other fields of employment might be suggested, but the foregoing will suffice to show the variety of uses it may and probably will be put to with advantage.

Thus far we have considered the use of storage batteries in connection with launches to the exclusion of any other electrical means. At the beginning of this article the present inferiority of primary batteries has been pointed out. It is needless to say that should the latter be brought to a state of efficiency and economy offering sufficient advantages over the former they would take the field. Instead of charging stations in the sense implied above, we would then substitute supply stations for chemicals or materials, or such other facilities as would be required for recharging, renewing, or regenerating the exhausted batteries.

There is a possibility also for a "direct" method of current supply on rivers or canals, employing conductors run overhead, or along the banks, on poles or other supports, although this plan would seem, in the light of present circumstances, to offer little more inducement than one involving the propulsion of road wagons or stages on a trackless road by an overhead method. Under exceptional conditions, however, such as for instance would be encountered in a very rapidly flowing river, a powerful floating motor, operated from an exterior source of current, undoubtedly could accomplish what might be impossible with any self-contained propeller. As for canal boats, it would be a difficult matter to combat the mule on the score of economy, while increased speed is not favored on account of the damage to the banks caused by the swell; for whatever sort of propeller may be devised to reduce the wash occasioned thereby (and who has not heard of the various arrangements designed to avoid it?), we cannot move a floating body, such as a boat, through water, without displacing, and consequently disturbing, the latter, to an extent proportional to the velocity of the boat.

The problem of producing electricity from heat direct to compete with steam, if brought to a successful issue, would probably affect navigation as much as any other field. Although the electric pleasure launch, to be devoid of the features accompanying the combustion of fuel, would even then carry its battery on board, an immense field would await the new generator in the larger vessels of commerce and—in conjunction with gigantic electric motors—even in the great ocean racers of the future.

In compliance with the request of the editors of THE ELECTRICAL ENGINEER, I give below an

ESTIMATE OF COST

of a fleet of 12 electric launches, each 28 feet long, 6 feet beam, carrying one ton of storage batteries, to run 6 miles per hour for 60 miles with one charge:

12 hulls complete, with interior fittings (battery troughs, seats and lockers), fixed roofs, shades, flag staffs, steering wheels, etc.,	$6,600
12 tons storage batteries (cap. 16,240 watt hrs. per ton) at $560 per ton,	6,720
12 motors, at $400,	4,800
12 screw propellers, shafts, couplings, thrust bearings and stuffing boxes,	1,200
Switches, wires, incand. lamps (4 per boat), with fittings,	480
Acid and labor of placing elec. outfit	1,200
Seat cushions, ropes, boat hooks, tools, pumps, etc.,	300
Total, 12 boats complete, in running order,	$21,300
or $1,775 each.	

CHARGING STATIONS.

Land and buildings (on suburb. water front) say,	$4,000
Steam plant, 60 h. p. complete, erected,	4,000
Dynamo, cap. 40,000 watts, with accessories, erected,	2,000
Charging circuits and appliances, erected,	250
Mooring facilities, tools, etc.,	500
Total cost of station, say,	$10,750
Grand total cost of 12 launches with charging facilities and real estate	32,050

ESTIMATED COST OF OPERATION.

It is assumed that each of the 12 launches makes a daily run of 60 miles, divided into 6 trips of 10 miles each (3 round trips) during 5 *months* in the year:

12 pilots at $2.50 per day each, for 5 months,	$4,500.00
1 station engineer, at $3 per day for 5 months,	450.00
1 station fireman at $2 per day for 5 months,	300.00
1 station laborer at $1.75 per day for 5 months,	262.50
Coal (4 lbs. per h. p. hour, 60 h. p. for 7 hrs. daily), 112½ tons (for 5 months) at $4 per ton,	450.00
Oil, waste, miscell. supplies and incidentals for 5 months, say,	200.00
Labor, etc., putting boats in running order at beginning and storing same at end of season, say,	360.00
Depreciation, per annum, on boats and propelling apparatus, at 10% on $21,300,	2,130.00
Depreciation of station machinery and appliances, at 6% per annum on $4,750,	285.00
Interest, per annum, at 6%, on interest of $32,050,	1,923.00
Total operat. expense, deprec'n and interest,	$10,860.50
or $905.04 per boat per annum.	
Total mileage run per boat per month (60 per day),	1,800 miles.
Total mileage run per boat in 5 months,	9,000 "
Total mileage run, 12 boats, at 9,000 miles each,	108,000 "

Cost of operation, including running expenses, depreciation and interest, as per above estimate, = $10\frac{6}{100}$ cents per boat mile. The boats assumed can seat 20 passengers and over. If an average of only *one-half* of this number is constantly carried, paying fare at the rate of *one cent per mile* each, the receipts will equal the operating expense, depreciation and interest on investment, as above.

The boats, in this instance, run at intervals of about 17 or 18 minutes (allowing for short stops), $1\frac{5}{8}$ miles apart, along the entire distance of 10 miles.

The cost and operating expense of electric launches will, of course, vary with different sizes and speeds, which the conditions and requirements of each distinct case contribute to determine.

BOGART'S NEW BURGLAR ALARM AND GAS LIGHTING APPARATUS.

NOTWITHSTANDING the vast amount of ingenuity displayed in the construction of devices intended to guard the premises of the householder, improvements are steadily going on in order to make assurance doubly sure and to forestall all possible conditions of unfaithfulness on the part of servants. Among the recent developments in this direction we may note the new combination burglar alarm annunciator of Mr. A. L. Bogart, of this city, which possesses a number of novel features not heretofore introduced in this class of apparatus.

The instrument, which is illustrated in the accompanying engraving, Fig. 1, is contained in a tastefully designed

FIG. 1.—BOGART'S IMPROVED BURGLAR ALARM.

case of fine finish and workmanship, the wood being chosen to match that of the apartment in which it is to be placed.

Besides being provided with all of the arrangements common to the most modern apparatus of its class, it includes a number of devices peculiar to itself. Thus, by pressing the "silent test" knob before retiring, the instrument indicates silently whether all of the doors and windows have been properly secured. It may be set to give an alarm only during the period that a door or window remains open, or to continuously ring the bell until the main switch is turned off.

An accurate regulator time piece is enclosed in the same case, which may be set to awaken the servant in the morning at any prescribed time. Heretofore an effort has been made to produce an extremely short contact in the clock, so as to limit the time during which the servant's bell shall ring, to from ten to twenty seconds. Owing to the lost motion which occurs even in the best make of clocks, such a short contact is liable to fail entirely. To obviate this

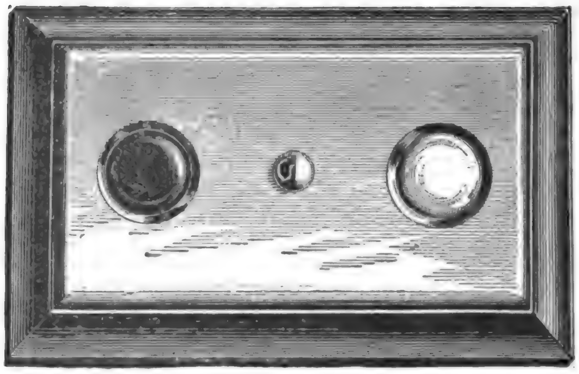


FIG. 2.—THE BARTHOLDI GAS LIGHTING PUSH BUTTON.

defect a long contact was usually made in the clock, but a switch was provided in the servant's room by which she could break the circuit on arising and thus cause the bell to cease ringing. The difficulty in this case consists in the fact that she either forgets to turn on her switch at night, or intentionally leaves it off.

In the Bogart burglar alarm both of these disadvantages are avoided by making a positive contact in the clock for at least five minutes. Under the alarm bell in the servant's

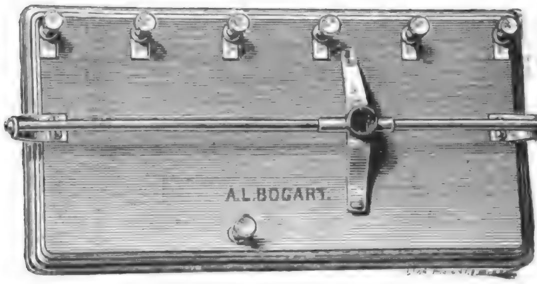

FIG. 7.—NEW MULTIPLE GAS LIGHTING SWITCH.

room is placed a push-button. When the bell sounds it is only necessary to press upon the button, when the clock switch on the face of the annunciator is automatically turned, cutting or opening the circuit to the bell. No pressure upon this button can affect the instrument in any manner, excepting only during the time that the bell is sounding.

By the act of pushing the button the servant also disconnects all such parts of the house as it is intended she shall have access to, from the burglar alarm, leaving the other apartments still connected. Unless she arises at the sounding of her alarm or waking bell, and pushes the button, the whole house remains connected and protected by the apparatus. The position of the clock switch will show in the morning whether she has arisen or not.

A special switch is provided, by which any number of automatic electric gas burners will be ignited should any of the doors or windows of the house be opened. Outside of the fact that in this instrument there is no limit to the number of automatic gas burners which can be practically simultaneously ignited in a house at the operation of the alarm, it varies from the usual forms in automatically cutting the current off from the burners as fast as lighted, thus preventing the possibility of the battery becoming run down through leaving it in circuit.

Another novelty consists in the method of giving the family admission to the house at night without sounding the alarm. At the front door is placed a small Yale-lock switch. By placing a key in the same, giving it a quarter

turn and removing it, a small clock movement in the annunciator case is electrically put into motion, which first disconnects the front door circuit and holds it open for a length of time amply sufficient for the party to unlock, open and close the front door after entering, when it again automatically closes the circuit restoring the alarm to its original condition.

Where electric gas lighting apparatus is installed in the house, a battery protector is included at the lower part of the case, as shown, which guards the gas lighting battery against accidental short-circuiting by disconnecting from the battery any circuit so grounded or short-circuited for more than the proper length of time.

The push-keys which have been ordinarily employed in connection with automatic electric gas lighting burners have proven one of the greatest annoyances to fitters in installing the apparatus, due to the fact that the connections are all in the rear, and, as a consequence, in connecting the three wires thereto, but one hand could be employed to place the wires in position and screw the washers down thereon, the other hand being employed in holding the button case. This inconvenience is greatly aggravated by the position in which the case must be held, particularly where the key is to be attached to a dead wall and the wires are consequently very short. Again, in such cases it is impossible to inspect the connections should any fault occur, without taking down the whole key, which causes the screw holes in the wall or plaster to break away and become mutilated about the key case.

Mr. Bogart has also designed a new form of button to overcome these disadvantages, and known as the "Bartholdi." Fig. 2 shows this key in perspective. It consists of a polished wooden base with a polished bronze, or brass, or nickel-plated cover having two buttons, one white and the other black, the cover being held in place by a single screw. Fig. 3 represents the base with the cover removed; the latter is shown reversed in Fig. 4. The connections, as will be seen, are all attached to the upper part of the base, which is attached to the wall and connections are made as with an ordinary push button. The springs on the cover hold the buttons in place and prevent them from falling out when it is being attached to the base. The cover may at any time be removed for inspection of the connections and contacts, which latter are supplied with platinum, without any necessity arising of removing the base from the wall.

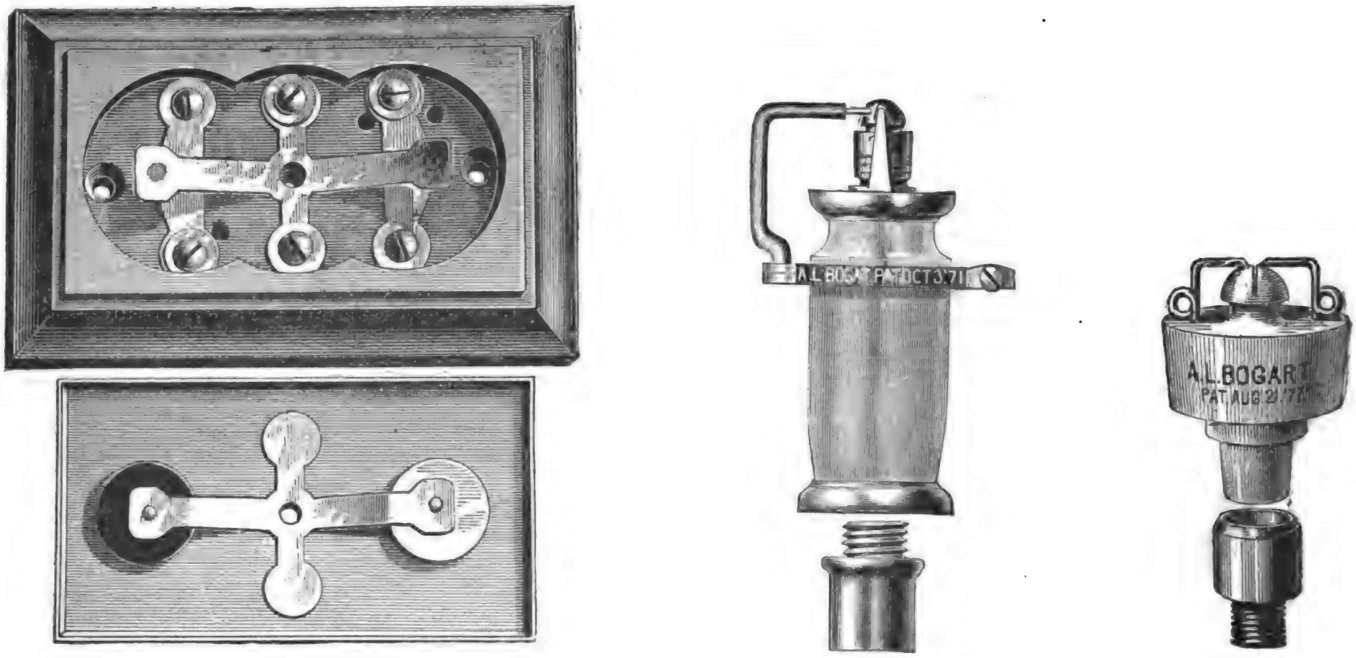
Mr. Bogart has also made some recent improvements in what is known as "multiple" electric gas lighting apparatus; that is, that class in which a series of gas burners are ignited simultaneously by means of a current of high electromotive force produced by either a static generator or induction coil.

An improvement in what is known as the "porcelain burner" is shown in Fig. 5. As originally constructed one of the spark electrodes was made a part of the tip, and as a consequence, a special tip had to be employed in case of repairs or alterations of size of the same. As will be seen, in the present form the tip electrode is independent, being constructed of a peculiarly formed piece of metal, which is held in position by the iron tip being screwed down upon it. It is readily adjusted in position; from its size and material it withstands the action of the flame, and any form of metal tip can be substituted for the original one, should a change be desirable.

Fig. 6 represents a new construction of "multiple" burner, where the flame is required to be at a lesser distance from the gas-pipe than would be permissible with the porcelain burner described above. The upper portion represents the burner with its electrodes, the material used as the insulator being entirely of steatite or lava. It terminates at the base with a taper nozzle which will fit into any ordinary burner pillar after the removal of the common lava tip. In case the gas fixture upon which the burners are to be used is supplied simply with iron tips or tip sockets, as in the case of reflector rings, then the metal socket shown below the burner is employed, it being provided with a quarter-inch (brass) thread. Fifty of these burners may be lighted in one series. In case a still shorter burner is required, the taper nozzle at the base of the burner may be removed, leaving a screw thread cut in the lava itself, for attachment to the fixture.

These burners are particularly adapted for use within imitation candle burners, the diameter being so small as to readily pass within the ordinary porcelain shell.

We also illustrate, in Fig. 7, a new form of multiple lighting switch, designed by Mr. Bogart, in cases where a number of series are to be lighted. The switch point slides horizontally, and thus makes the connection of the circuit wires more convenient than where the switch lever revolves, and the latter cannot slip out of position, remaining wherever placed.



Figs. 3, 4, 5 and 6.—Bartholdi Gas Lighting Push Button, and New Multiple Burners.

ELECTRIC RAILWAYS AND OCEAN CABLES.

BY T. D. LOCKWOOD.

I HAVE read with a good deal of interest the communication of Mr. Cuttriss, in THE ELECTRICAL ENGINEER of August 6, concerning the disturbances manifested in his cable receiving instruments, which he attributes to the operation of an electric street railway at a distance of upwards of half a mile therefrom; and with equal interest the editorial comment on said article.

Though it is doubtless often unpleasant to be like Mr. Cuttriss and myself on the physically weaker side of a controversy, that position is not without its offsetting advantages, in that we are forced to study, and let us hope sometimes to master, the problems they involve; while persons working with less delicate appliances and with the electrical pursuits which cause, as distinguished from those which suffer from, the disturbances, are often and naturally content with a perfunctory examination of the matter.

As I have read the two articles, I gather that the disturbed cable circuit comes into the station from the sea conductor, passes through the instruments at the said station and then back by way of a closely parallel insulated conductor in the same cable to earth at the cable armor.

If I have correctly interpreted the arrangement, it is first to be observed that it is not as stated in the editorial comment "a complete metallic circuit," but simply a loop of an earth completed circuit, the two wires of said loop being parallel.

I should scarcely expect that any such disturbances as are described arise from magnetic induction, and in the light of experience do not believe they do, not so much, however, because the wires are looped for a certain distance, as from the fact that in addition to said looping, they are buried; they are underground; both conditions would tend I think to adversely affect magnetic induction.

I am inclined to believe that the disturbances have a twofold cause; that they are partly due, as Mr. Cuttriss suggests, to actual conduction through the intervening earth and water from the earth side of the electric railway circuit to the cable armor, and thence by way of that conductor, which is grounded on the armor, and through the instruments to the cable main conductor; and also in part attributable to the actions and reactions of electrostatic induction, which in such a case are likely to be complicated.

We may consider the earth, if of favorable constitution, to be heavily charged by the electricity poured into it from the cars.

It is not difficult to conceive that such a charge in the medium surrounding the buried cable will tend to attract a like charge of opposing sign, through the dielectric on both conductors of the cable. Thus if the earth be charged to a given plus potential by the railway, the two parallel conductors of the cable loop will both be the recipients of a minus charge. But this charge must come from somewhere, and as the armor earth terminal is nearer than any other, the major part of it comes from that point. But there is another reaction; the two sides of the loop are of unequal length, and it may well be imagined that the charge on the short side, that grounded on the cable armor is thicker, if I may so express it, than is that on the long leg which is but the end of the main cable conductor. The two will tend to react on each other, and the amount of the perceptible reaction will be the difference of the two charges.

But of course, any change in the potential or degree of charge in the surrounding earth, will eventuate in a redistribution, and a rearrangement of the charge in the cable; and such a rearrangement amounts virtually to a circulation of current. And as all changes or transfers of electricity from one side of the loop to the other must pass through the instrument, we necessarily have the undesired operation of the said instrument.

The editorial says: "There will, of course, be a solution for the difficulty, but it will be interesting to see just what it is." The solution of the difficulty is, in my opinion simply the use by either party of the complete parallel wire metallic circuit, imperfectly and at a high cost, by the cable company, whose property is trespassed upon; or in a practically perfect way, at a comparatively low cost, by the railway company, who is doing the tresspassing.

POWER TRANSMISSION IN FRANCE.

AT the recent meeting of the Société Internationale des Electriciens M. Hillairet described the interesting transmission of power by electricity which has been carried out near the town of Doméne in Isère, France. In this installation power equal to 200 h. p. delivered is transmitted to a paper mill at a distance of $3\frac{1}{4}$ miles from the waterfall utilized. Lantern slides from photographs taken last winter were shown giving different views of this installation from the waterfall and works passing along to the motor, with all the accessories necessary for the transmission. An interesting feature of the installation is that during the winter the little generating works is entirely cut off by the snows for two months from the paper mill where the force is utilized, but nevertheless continues to work regularly. The telephone enables it to be known whether all is going well, and keeps up communication with the inhabitants of the valley.

DISCHARGE THROUGH A LIGHTNING ARRESTER.

THE following description of a lightning stroke has been sent to the *Victorian Telegraphic Journal* by Mr. James M'Carter, of Melbourne:—"Recently during thunder and lightning, without rain, I 'cut out,' and shortly afterwards was shocked by seeing the office apparently ablaze, and hearing a terrific report, similar to that of a gun, but much louder. I fully expected to find the whole front of the office smashed in, and could hardly credit, on examination, that the only damage done was several of the screw points of the arrester fused. The point of one screw was flattened on to the centre plate, resembling a small coin. I scraped this off, and found there was an indent on the earth plate."

SOME DETAILS OF THE PERAL SUB-MARINE BOATS.

The Peral electric sub-marine torpedo boat is of the usual cigar shape, and is provided with four screws, two vertical ones for effecting immersion and two for purposes of propulsion. The screws are driven by Immisch motors energized by Julien accumulators. If any accident occurs to the motors and the immersion screws are stopped, the boat rises at once to the surface without further aid, though, of course, the emptying of the water compartments hastens the ascension. To avoid an undue expenditure of power in connection with the immersion screws, the water compartments are filled to an amount which enables a very slight motion of the screws to sink the boat to the required depth and maintain it there. The automatic apparatus which regulates the depth at which the boat is to work is designed on a principle somewhat similar to that of the aneroid barometer. A curved tube of elliptical section is placed in connection with the sea, and its deformations due to the alterations of pressure actuate a switch, by which the strength of the current going to the immersion screws is varied. The positions of the contacts of the switch are altered to suit the particular depth at which it is required to work. A very sensitive automatic electrical device is also employed to keep the vessel in a horizontal position. The apparatus consists of a pendulum playing between two contacts. If the boat is not perfectly level from stem to stern, the pendulum touches one of the two contacts, and the result is that the corresponding vertical screw is actuated and the boat is righted. The speed which the inventor hoped to realize, namely, ten miles an hour, has been much exceeded.

THE BROOKLYN INSTITUTE'S ELECTRICAL LECTURES.

The Executive Committee of the Department of Electricity of the Brooklyn Institute is now planning the work for the coming year on a very practical and extensive scale. For the lecture course they have arranged for 24 lectures to be given by leading electricians and electrical engineers who have the faculty of speaking before an audience. Sixteen of the 24 have already been secured by Prof. F. W. Hooper, who is now making arrangements for the rest.

THE WORKING EFFICIENCY OF SECONDARY CELLS.[1]

BY W. E. AYRTON; C. G. LAMB, E. W. SMITH AND M. W. WOODS, ASSOCIATES.

SINCE 1881, when the formation of Plauté storage cells was greatly accelerated by Faure's device of pasting the plates, numerous tests have been made in different parts of the world on the capacity and efficiency of secondary cells. The first tests that were carried out were conducted simultaneously, at the end of 1881, in England by Prof. Perry and in France by a committee consisting of Messrs. Tresca, Potier, Joubert and Allard.

The "resuscitating power" made it very difficult to say when a cell was discharged completely, and the beginning and end of a test was indeterminate.

In the author's method the cells were "emptied" until the discharge was barely perceptible; then they were short-circuited with a short, thick wire, being at the time insulated, and thoroughly discharged for three successive days and allowed to recuperate in the two intervening nights.

The efficiency obtained by this treatment was not less than 82 per cent., and naturally much more than could be obtained in practice, as the point to which the E. M. F. might profitably be allowed to fall is far above the comparative exhaustion recorded. Still, it was reliable in the sense that all the energy put into the cells reappeared without any reinforcing from unexpended energy formerly put into the cells, but the resuscitating power had ample chance for its operation.

The French commission considered the cells discharged when a current that was produced through a specific resistance could no longer be kept up. Provided the cells had undergone a thorough discharging before trial, this method seems to be as accurate as need be, but no evidence of this occurring appears in the report, and it is not impossible that the cells were drawing upon a store of energy put into them on previous trials and giving a higher value than the working efficiency; and a very possible neglect of the powerful resuscitating power of accumulators may have vitiated some of the published results of experiments that have been made on them. This doubt must not be forgotten in considering the accompanying list, which is as complete as it has been able to make it, of all such experiments that have been made up to date. At the middle of 1889, when the author's investigation had been nearly completed, there appeared two very important contributions to the subject—one on "The Inherent Defects of Secondary Batteries," by Dr. Louis Duncan and H. Wiegand; the other, "Ergebnisse von Versuchen an Akkumulatoren für Stationsbetrieb," by Prof. W. Kohlrausch and C. Heim.

Kohlrausch and Heim lay great stress on the fact the discharge of accumulators depends not only on previous discharge but also on the previous history of the cells.

At the inception of Prof. Ayrton's test the question arose whether to maintain a constant resistance of circuit or to vary it, as the E. M. F. fell, in ratio to maintain a constant current. The latter method was adopted, and, in order to dispense with manual intervention and the constant personal attention of an observer to start the charging directly upon the conventional discharge ceasing and eliminate any chance of error as to duration of the experiment, an automatic arrangement was employed which maintained a current more uniform than the most adroit hand-regulation, and broke the circuit between charging, discharging and vice versa, when the P. D. touched the predetermined limit.

There is a popular faith in certain checks upon the foregoing process, such as the variation of specific gravity of the solution, which was found to vary directly with the duration of a constant current, amounting to about .002 per hour, a coefficient without the scope of any average hydrometer and useless in itself as a method of precision. The sudden plunge in the diagram of potential near the termination of a discharge is a very potent factor in the summation. The feature of "gassing" only amounts to a rough test, is not applicable to discharge, and may fairly be neglected in estimating efficiency and energy.

A number of experiments were made on two of the cells in order that the *exact* shape of the curves of P.D. at the *end* of the charge and discharge might be ascertained. The curve shown in Fig. 1 is the end of the P.D. curve for one cell on charging with 9 amperes for 14 hours; from which it is seen that the rate of variation of the P. D. with time is greatest when the P.D. is about 2.36 volts, indicated by the point A. In Fig. 2 is shown the curve of P.D. during the last 3½ hours of a discharge with 10 amperes, the discharge being continued for 12 hours. In this particular experiment the discharge was allowed to continue until the P.D. fell to 1.365 volts, indicated by the point C, which is far lower than the P.D. was allowed to fall on any other occasion. At about 1.8 volts the P.D. curve begins to fall pretty rapidly, and the slope of the curve, or the rate of diminution of the P.D. with time, goes on increasing until the P.D. has fallen to 1.6 volts, indicated by the

					The positive plates of these Tudor cells are first formed by Planté's process, then the holes in the grids are filled with minium, and the forming continued. The negative grids are not formed at all, but merely have the holes in the grids filled with lead oxide.

1. Abstract of a paper read before the Institution of Electrical Engineers at Edinburgh, July 16, 1890.

point A on the curve in Fig. 2. Here $\frac{dV}{dt}$ per cell has reached a value 1.4 V being measured in volts and t in hours. Below this the curve has a shape that has not hitherto been noticed, for when the P.D. per cell has reached 1.556 volts, indicated by the point B, the curve suddenly alters its shape, becoming the straight line B C, with a less inclination to the axis of time, $\frac{dV}{dt}$ being for this line only 0.44.

Just as in the curve in Fig. 2 the discharge has been continued much below the usual limit, so what would take place if the charging was also prolonged much beyond the usual limit was examined. Fig. 3 shows the rise of the P.D. when the charging at 4.52 amperes was continued for 37¼ hours, 25¼ hours being sufficient to fully charge the cells with this constant current of 4.52 amperes—that is, to charge them until the P.D. per cell was 2.4 volts. It will be observed that whereas the volts rise from 2.25 to 2.38 between 23.1 and 25.5 hours—that is, 0.13 volt per cell in 2.4 hours—the rise in the following 12.3 hours is only from 2.38 to 2.55 volts, this is, only 0.17 volt. The continuation of the curve shows the drop of P.D. on breaking the charging circuit: there is an instantaneous fall of 0.28 volt per cell, and a further fall of 0.1 volt in the E. M. F. in two hours.

The curve in Fig. 4 shows on a larger scale this drop on breaking the charging circuit when the cells are very well charged,

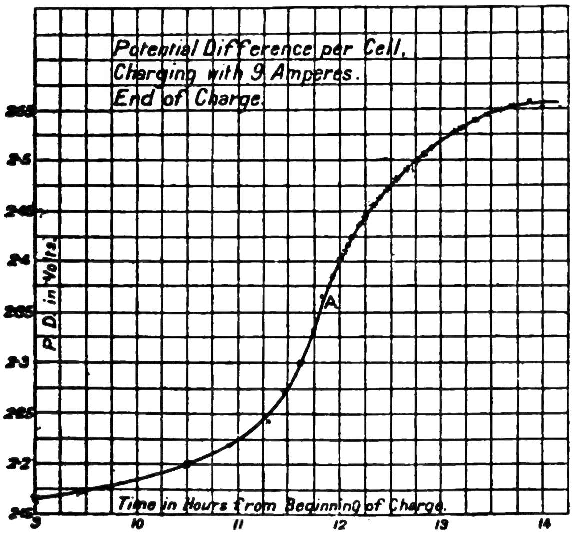

Fig. 1.

leaving it broken for five minutes, and then closing it again; the charging current in this experiment being 9 amperes. There is, as will be seen, a nearly instantaneous drop of the terminal P.D. per cell from 2.56 to 2.31, then a steady fall in the E.M.F. from 2.31 to 2.24 volts in five minutes. On reclosing the charging circuit at this moment, there is an instantaneous rise of the P.D. to 2.48 volts, and then a slow rise to 2.56 volts in five minutes; so that after reclosing the charging circuit it took, in this experiment, the same time for the P.D. to recover the value it had just before breaking as the time during which the circuit remained broken.

Experiments were also made on the time rise of the E.M.F. on stopping the discharge. Later on, however, the time rise of the E.M.F. on breaking the discharge circuit, as well as the time fall of the E.M.F. on breaking the charging circuit, for various currents, was measured in a far more sensitive way than in the early part of the investigation.

On starting a discharge the P.D. generally falls slightly to the value that is maintained fairly constantly during a long portion of a discharge. After a prolonged rest, however, it was found that the P.D., on the contrary, shows a *decided rise* at the commencement of a discharge, and that it is not until the third discharge takes place that the curve resumes its normal character with the slight drop in the value of the P.D. at the commencement of the discharge.

EFFICIENCY.

In the earlier experiments made on the quality of efficiency great care was taken as to the accuracy of the instruments used; special calibration of them was made previous to, and at the conclusion of, the experiments.

The coarse adjustment of the resistance for keeping the current constant was effected by means of resistance coils made of bare German silver wire suitable for standing large currents; the fine adjustment was performed by means of horizontal mercury troughs through which the current passed, the lengths of the mercury in the wooden troughs through which the current passed being varied by copper bridge-pieces. The mercury trough arrangement forms an extremely convenient resistance for delicate adjustment by hand. To keep the current as constant as possible a dynamo was not used to charge the accumulators under test, but they were charged instead from other accumulators of much greater storage capacity.

The problem of keeping the surface of the mercury clean solved itself after the failure of all supposed remedies. Alcohol dried up, water electrolyzed, oil carbonized and long spiculae grew upon each platinum point until the auxiliary accumulators referred to later were short-circuited. By being left entirely alone, a thickish layer of mercury and mercurous oxide formed on top, through which the platinum points easily penetrated and made perfect contact.

Some practical limitations to the refinements of laboratory experiments are significantly accented by the appended tables:

Group of 10 *Cells—No. I.*

Discharge at 9.933 Amperes.		Charge at 9.05 Amperes.		Percentage.	
Ampere-Hours.	Watt-Hours.	Ampere-Hours.	Watt-Hours.	Quantity Efficiency.	Energy Efficiency.
119	2,280	114	2,435	105	94
105	2,045	102	2,220	103	92
101	1,970	101	2,220	100	87
104	2,020	104	2,270	100	89
Discharge at 9.933 Amperes.		Charge at 4.519 Amperes.			
112.5	2,170	115	2,485	98	87
113	2,190	115	2,485	98	88

Group of 10 *Cells—No. II.*

Discharge at 4.858 Amperes.		Charge at 9.104 Amperes.		Percentage.	
Ampere-Hours.	Watt-Hours.	Ampere-Hours.	Watt-Hours.	Quantity Efficiency.	Energy Efficiency.
154.5	3,005	138.5	2,910	111.5	103
141.5	2,770	129.7	2,820	109	98
Discharge at 4.858 Amperes,		Charge at 4.519 Amperes.			
143	2,785	141	3,075	102	90.5

Now not only are quantity efficiencies of 105, 103, 111, 109, etc., per cent. impossible, but energy efficiencies of 94, 92 per cent. are also too high, when accumulators are being charged and discharged at the maximum rate allowed by the manufacturers. Further, it is noticeable that for each set of tests both the quantity and energy efficiencies diminish on the whole as the tests proceed. These cells, like the other cells in the Central Institution laboratories, have been charged at regular times; and as the number of ampere-hours taken out of them for ordinary laboratory work varies very much, the intervals between the periodic chargings are so arranged that, on the whole, the cells are charged up much more than they are discharged.

Hence at the commencement of these tests the cells had a large store of energy in them on which to draw in the discharges, the results of which are given in the preceding table. From this we learn this very important fact—that *if accumulators be thoroughly well charged up before being tested, then five days' continuous charging and discharging alternately with even the maximum currents allowed by the manufacturers fails to give the normal quantity, or energy, efficiency.*

It will be noticed that both the ampere-hours and the watt-hours are increased by diminishing the current employed. This is partly due to the fact that if a fixed P.D. limit per cell be employed either in discharging or charging, the cell is discharged until the E.M.F. is slightly lower, and charged until the E.M.F. is slightly higher for a small current than for a larger one.

The following special appliance was used to regulate the current. An independent current for the sole purpose of working the current regulator finds its way through a platinoid strip of sufficient section and surface to entail 110 appreciable change of resistance to the 10 ampere current following through it. A permanent magneto-electric machine turns a brass roller in either direction, with angular velocity, no greater than $\frac{1}{300}$ that of the magneto's armature. The roller is electrically divided and turns with a minimum friction in its journal. Platinoid wires, uninsulated,

envelop each half of the roller, their lower ends soldered to the rollers and upper ends to a brass bar balanced through suspension over pulleys.

A current entering the roller axis finds its way through one-half roller up to the swing-bar, down to the opposite half roller and to the bearing opposite to that by which it entered. Thence it passes to a solenoid, whose deli ately hung core is confined solely to axial motion by the use of two strings at each end, the upper ends of each couple spread apart, and the lower ends uniting at a common point of suspension at an extremity of the core. The core communicates with a platinoid spiral spring which required a certain period of use to arrive at a constant coefficient of elasticity, and its precision is remarkable.

The charging current from an outside battery finds its way through the platinized strip, the swinging brass roller, the solenoid and back to the battery to the opposite pole. If this current exceeds the predicated limit, the solenoid plunger makes a contact which by revolution of the brass roller increases the resistance in its circuit, or in the opposite contingency, by contrary motion, decreases it. The deviation for days at a time does not exceed $\frac{1}{100}$.

It was very interesting to watch the regulator, as the armature of the motor was almost always in motion, now making half a turn one way and then a full one the other. One turn of the armature shortens or lengthens the platinoid wires about 0.16 inch, or one three-thousandth of its own entire length.

What effect rest has upon accumulators was demonstrated by five periods of inaction; the average of the five being fourteen days. They showed a reduction of 26 per cent. in quantity and the same in energy, confirming Kohlrausch in his view that

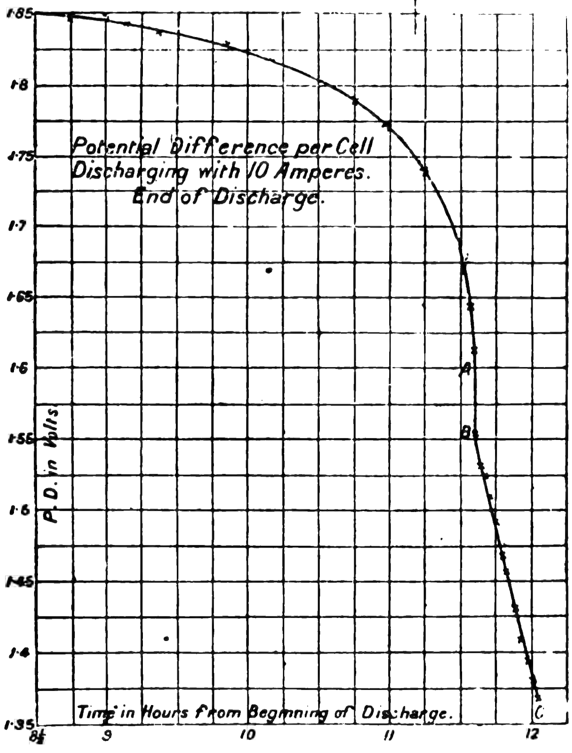

FIG. 2.

previous history has everything to do with a cell's efficiency. The fact of the P. D. rising during the first hour of discharge proves their abnormal character.

Dr. Frankland has shown that an accumulator discharge evolves the special lead salts (which are formulated as $Pb_3 S_2 O_{10}$. and $Pb_5 S_3 O_{14}$.) on account of the difficulty of electrolytically decomposing white sulphate of lead. It appears from the tests that the rise of temperature of the cell during charging may, after allowing for changes of temperature of the room, be either about 1.3° C. or 0.77° C., while the fall of temperature during discharging may have either of the two preceding values. It is further interesting to notice that the rise of temperature during the charging has the higher or the lower of these two values according as the fall of temperature during the previous discharge had the higher or the lower value.

About a year later another set of *continuous* temperature observations was made for many days and nights with the same cells, the current in discharging and charging being, as before, 10 and 9 amperes respectively. The higher P.D. limit was, as before, 2.4 volts per cell, but the discharge was in each case in this second set of continuous discharges and charges stopped at 1.9 instead of 1.8 volts per cell. As the regulation of the current day and night was in these later experiments in 1890 effected by hand, it was not kept quite as constant as when the automatic regulator was employed. Hence the time curves for the excess temperature in discharging and charging, when plotted, were not found to be as regular as in the previous case.

It was observed that in these experiments not merely does the excess of the temperature of the working cell over that of the idle cell fall during the discharge, but it actually continued to fall at the commencement of the charge.

Allusion is made to the measurement of the resistance of accumulators by observations covering day and night, to determine the resistance during the entire discharge and charge for various currents. For each of these currents the cells are being brought

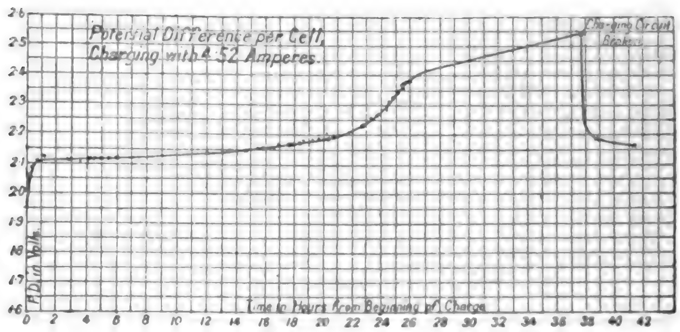

FIG. 3.

to a steady working state by many discharges and charges being successively and without interruption made with each current. In the case of the small current the time of a charge and discharge is tediously long, the charge, for example, with 8 amperes requiring 40 hours to raise the P.D. from 1.9 to 2.4 volts per cell, so that several weeks have to be spent obtaining the resistance for this current. This investigation of resistance is not yet completed, and the authors do not in this paper refer to the variation of the resistance of a cell with different currents when the cell is brought to a *steady working state for each current*. Such an experiment has not, as far as the authors are aware, ever before been attempted with accumulators; former observers have contented themselves with merely observing the variation of the resistance when the current during discharge or charge was abruptly

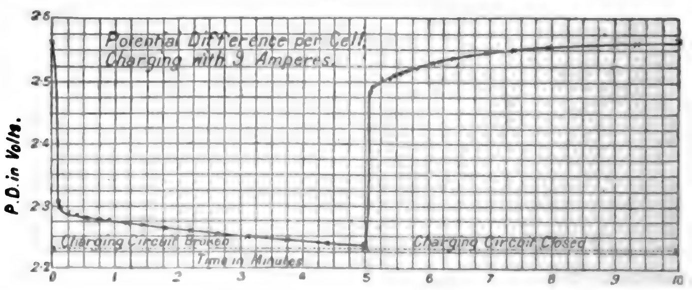

FIG. 4.

changed from one value to another. This is a very different thing from ascertaining how the resistance of an accumulator varies with the current when *each* of the different currents employed is steadily used for some weeks in the discharging and charging of the cell, until the cell has arrived at a steady working state for the current in question.

It is stated, in conclusion, that the results obtained with accumulators made to go for long periods through definite cycles in charging and discharging, having been so interesting that the authors are now engaged on the design of an apparatus which will automatically keep the current constant for any time at any pre-arranged value, which will automatically change over from charge to discharge, or from discharge to charge, when the P.D. per cell reaches any pre-arranged limit, and which will record the P.D. at the terminals of the cell, and also its E.M.F. during the whole period. They hope, therefore, at some future period to be able to present a graphical record of the life-history of accumulators from their first formation to their death.

THE NEW CABLE TO FRANCE.—M. Jules Roche asks $80,000 of the Chamber for a new telegraphic cable between France and England. The existing cables can hardly meet the increased demand for their services which rose last year during the exhibition. M. Jules Roche calculates that the entire cost to France of this telegraphic enterprise will be nearly $140,000. Last year the increased profit to the State, in consequence of the increased business, was over $75,000.

CORRESPONDENCE.

MINNEAPOLIS.

The Approaching Electrical Exhibition.—The Edison Convention.

The electrical exhibit which is to be made at the Minneapolis Exposition, which opens August 27th, and closes October 4th, will be the most complete display of its kind ever made. It will include not only the Edison exhibit made at the Paris Exposition in 1889, but will be more complete in every way, and in addition will contain an exhibit by the Thomson Electric Welding Company, of Lynn, Mass. The Edison exhibit is already on the ground, and is being arranged under the direction of Luther Stieringer, of New York. Nearly three car loads of electrical material to be used in the exhibit have arrived. The principal feature is a "Tower of Glory," the plans for which were drawn by Mr. Stieringer. The tower has been built in the centre of the building and is about 70 feet high and 8 feet in central diameter. It is of Egyptian design and is to be covered with 7500 incandescent lamps. From the top of the tower festoons of lamps will hang in various designs, making it the most brilliant lighting spectacle in the world. The Edison exhibit includes the talking dolls and an electric railroad, the various telephone devices, the telegraph instruments as seen in Paris and at the Lenox Lyceum, the phonographs, dynamos, etc. The working of all this apparatus is to be illustrated by experts from Edison laboratory. The Thomson electric welding apparatus, by which dissimilar metals are united, will also be in actual operation, and much interest is being manifested in the exhibit. Mr. W. M. Regan is general manager of the exhibition.

The convention of the Edison Illuminating Compannies will be held in Minneapolis, September 16th. A large number of delegates are expected to be present. There will also be a very extensive exhibit by the Carpenter-Nevens Electric Heating Co., who will have in practical operation a variety of very recently patented electrical apparatus, soldering tin-ware, ironing laundry-work, pressing clothing, frying doughnuts, etc., and various other appliances of heat by electricity. There will also be a very extensive exhibit by the power department of the Edison General Company, and a very extensive line of exhibits in electrical merchandise and apparatus.

MINNEAPOLIS, Aug. 7, 1890.

CHICAGO.

An Electric Fountain for Lincoln Park.—The Calumet Electric Railway.—Electric Railway Notes.

The new electric fountain presented by C. T. Yerkes to the Lincoln Park commissioners, which has been in course of erection for several months, is now about completed. It is probably the largest one of its class in the country. The fountain contains over 200 large jets, all of which are in play together and throw varying streams to the height of seventy-five feet. In addition to these there are numerous smaller jets which furnish an abundance of spray. The electrical part of the fountain is not yet entirely completed but will be finished in a few days, when a formal opening will probably be made, with music and other features. It is stated that the making of such a gift was first suggested to the donor during a visit to the Paris Exhibition, where the prismatic fountain proved to be one of the leading features of the display; and immediately on his return the offer was made to the commissioners to place a similar one in Lincoln Park, which was gladly accepted.

The fountain when completed will be one of the most beautiful and novel sights imaginable. The spray, sent up to a great height, will separate into innumerable drops, each of which, like a prism, will reflect the light thrown upon it by the electric lights and shine like diamonds. The fountain, when complete, will represent a cost of $50,000. In repose the fountain is not an imposing affair, the visible portion being a maze of pipes and tubes within a circular wall. It is on the Lake Shore drive near the ball grounds. When the pumps are at work, and the light thrown on it, the fountain will present a most beautiful and striking appearance. A very satisfactory test of the fountain has now been made.

Prof. Barrett will soon place electric lights in that section of the South Side lying between the river and Twenty-second street. The power house is being built on Fourteenth street and Indiana avenue.

The complications which have retarded the work on the Calumet electric railway are being removed and the road will be rapidly pushed forward. The city council has passed an ordinance extending the time in which the first section of the road, from the works of the Illinois Steel Company, in South Chicago, to Stoney Island avenue, must be laid, and J. J. Harvey, the president of the road, has agreed to the conditions exacted by the council. Two blocks of track on Ninety-third street, and about a block on South Chicago avenue, have been laid, and work on the eastern portion, near Calumet Heights and Dauphin Park, has been steadily carried on. It is expected that cross lines will be run due east from this line to the country lying in the vicinity of Washington Heights and Fernwood. It is said that efforts are being made to avoid the use of the overhead trolley system; and an entirely new system, by which only the part of the rail over which the car is passing will be charged, is now under consideration.

At Joliet last week a telephone wire on Cass street broke and fell on the electric railway wire. This carried an electric current into the central office, which set fire to the switchboard. The cable consisting of one hundred conductors was burned out. It is a pity the telephone wires are not kept in better condition.

The Chicago and Lake Shore electric railway was incorporated last week, the names of the incorporators being F. L. Brooks, C. H. Romy and George A. Fairbanks. This project has been under consideration for several months, and provides for a fully equipped electric road, parallel with, and as near as possible to, the north lake shore from Chicago to Fort Sheridan, and later to be continued along the lake to Waukegan. The estimated cost of the first section of the road is $1,500,000, and it is to be put in such condition that passengers may be carried from Chicago to Fort Sheridan, a distance of twenty-five miles, in fifty minutes. Mr. C. H. Remy states that the backers of the scheme are Pittsburgh and Boston capitalists, that the road is to be built, and negotiations are already going on for the right of way. It is rumored that the Westinghouse Electric Company is interested in the scheme. It is also reported that Mr. Westinghouse has just perfected a motor car that will do away with overhead wires entirely in the business centres, using them only on a part of the line. This motor will have properties enabling it to accumulate energy while being propelled by the current from the overhead wire, thus combining the overhead system with the storage system.

CHICAGO, Aug. 9, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

SOME REMARKS ON ELECTRICAL VIVISECTION.

[133.]—Now, that the long-deferred Kemmler execution has taken place, it may be well to look a little more closely at some of the circumstances surrounding the case, which have so far not received attention.

During the taking of the testimony before a referee, a large number of witnesses were examined, some for and some against the carrying out of the sentence in the manner and by the means which were finally employed. It must be remembered that none of these latter witnesses contended that electricity would not kill. Their only contention was that the use of a commercial machine of only 1,000 volts tension would not render death either instantaneous or painless.

On the other hand, a number of supposed scientists and medical men contended that the merest touch of a wire carrying 1,000 volts would most certainly be fatal, and painlessly so. None of these scientists and doctors would admit ever having received a shock of even ordinary severity, and reasoned entirely from theory, or from experiments on animals; experiments which were never conducted in a manner calculated to give any exact knowledge of the circumstance and conditions. Not only this, but men who testified that they had received without serious injury, but with indescribable agony, shocks from machines of this description (with bare hands, perhaps greasy, perhaps wet, and their conditions of contact varying from a firm grasp to a mere touch) were laughed at, and all but openly accused of perjury.

The only experiment which can have any real value in determining what will kill a human being, that is, an experiment *on* a human being, has taken place, and already these doctors and scientists are giving their widely differing opinions as to the reasons for the disgraceful exhibition which took place. One scientist has already stated that it was because the contacts were made with the head and spine, instead of through the hands. We may shortly expect another to claim that the shock should have been given from the head to the feet, as was originally designed. In short, when doctors disagree, who shall decide?

That death was not instantaneous must be conceded. That the death was painless, all the doctors are very sure. This may be a very comfortable and satisfying conclusion for them to reach, but there is another view to be taken. Seeing that these doctors were certain that death would be instantaneous, and that in spite of months of careful preparation, with the current applied under

conditions vastly more favorable to death than ever before, that death did not take place after an application of the current for 17 seconds, and that the victim began to revive after four doctors had pronounced him dead, thinking people may well inquire whether it would not have been well to lay a little more stress on the testimony of witnesses before the referee, who contended that death would be intensely painful even if sure, and that the machine to be used for the purpose was an improper one. It is but scant justice to these witnesses who have been so much maligned to call attention to the utter refutation of the medical testimony afforded by the scene in Auburn Prison, and the strong corroboration of the testimony of the many linemen and others who were hooted at because they claimed that they had survived shocks from the same apparatus, but far less severe than that with which it was attempted to kill Kemmler.

ONE OF THE WITNESSES BEFORE THE REFEREE.

REPORTS OF COMPANIES.

PACIFIC POSTAL TELEGRAPH. CO.

The annual meeting of the Pacific Postal Telegraph Company was held at 1 Broadway on August 5, and these directors were elected: John W. Mackay, W. C. Van Horne, George Stephens, Charles R. Hosmer, Richard V. Dey, Albert B. Chandler, Hector De Castro, Edward C. Platt, and George G. Ward. The Pacific Postal is a line of telegraph running along the Pacific Coast. As the names of the directors show, it is closely related to the Postal Telegraph and Cable Company.

ERIE TELEPHONE CO.

A quarterly dividend of 1 per cent. has been declared on Erie Telephone stock, payable Aug. 18, to stockholders of record Aug. 8. Books closed from Aug. 8 to Aug. 17, inclusive. The combined report of the Cleveland Telephone Company, the Northwestern Telephone Exchange Company, and the Southwestern Telegraph & Telephone Company, for the three months ended June 30, 1890, is as follows:

QUARTER ENDED JUNE 30.

	1890.	1889.		
Gross	$189,393	$177,068	Inc.	$12,304
*Expenses	131,549	118,672	Inc.	12,877
Net	$57,843	$58,461	Dec.	$578
Dividends	48,000	48,000		....
Surplus	$9,843	$10,416	Dec.	$578

SUBSCRIBERS ADDED.

	1890.	1889.		
Quarter	417	249	Inc.	168
Total connected, July 1	12,662	11,564	Inc.	1,098

*Includes construction.

The increase in the expenses undoubtedly indicates a large amount of construction work going on. The surplus is over $7,000 in excess of the previous quarter's surplus. The three subcompanies, after paying all their expenses and the dividends to the Bell and Erie companies, retain a surplus of $9,843. The Erie company, after paying one per cent. from its portion of the dividend received from the three companies, reserves $8,601, or a total surplus for the quarter of $18,444. The increased earnings and surplus are attributed to the large increase of subscribers, 250 having been added the first quarter of this year, and 417 the second, or a total of 667 in six months. The Erie company now has a cash surplus exceeding $73,000.

UNION TELEGRAPH & TELEPHONE CO.

The directors of the Union Telegraph & Telephone Company (operating in the State of New York) have declared a dividend of one per cent., payable Aug. 18 to stockholders of record Aug. 8. The quarterly statement is as follows.

QUARTER ENDED JUNE 30.

Gross earnings	$6,216
Expenses and construction	5,107
Net earnings	$1,109
Dividend	1,000
Surplus	$ 109
Total surplus, June 30	$1,258
Number of subscribers	506

DIVIDENDS.

TROPICAL AMERICAN TELEPHONE CO.—At a meeting of the directors of the Tropical American Telephone Company, held August 5, it was voted to pay a dividend of 1 per cent. or 10 cents per share on the 15th day of August, to stockholders of record August 1st, and a further dividend of 10 cents per share on the 1st day of October to stock of record September 15th, and that in future the dividend days will be April 1st and October 1st. The general manager's report showed a gain of nearly 100 per cent. over the preceding year, and the treasurer's report showed $24,000 and about $25,000 bills receivable in excess of debts. Mr. Harry Highley was elected secretary and treasurer.

QUINCY, MASS.—The Quincy Electric Light and Power Co. has declared a dividend of 5 per cent.

THE AUTOMATIC FIRE ALARM AND EXTINGUISHER CO., L't'd., of 413 Broadway, this city, has declared a dividend of 2 per cent., payable August 15.

FINANCIAL MARKET.

QUOTATIONS OF ELECTRICAL STOCKS.

Mr. F. Z. Maguire, Electrical Securities, of 18 Wall street, this city, reports the following quotations of August 9 from New York, Boston and Washington:—

NEW YORK.

METAL AND SUPPLY MARKET.

COPPER PRICES.

Quietude has characterized the Metal Exchange for another week. Copper fell off slightly from August 1 to August 8; margins were called to 17 cents on the 1st and to 16.80 cents on the 8th. Official closing figures of 8th, compared with a week previous and a year ago, are given as follows:

	August 8.	August 1, 1890.	August 9, 1889.
Straits tin, spot	20.90	20.80	19.95
Straits tin, Oct	20.90	20.90	19.95
Lake copper, Aug	16.80	17.00	11.80
G. M. copper, Aug	—	—	9.50
Domestic lead, spot	4.45	4.45	3.85
Domestic spelter, Aug	5.40	5.40	—

SHIP SIGNALING TELEGRAPHY.

Commander Percy Scott, of her Majesty's ship "Excellent," has designed a flash signaling lantern to enable flash signals to be sent on the Morse system with greater rapidity than has heretofore been possible and from a point where the present mechanical arrangement of shutter could not well be employed. The lamp is surrounded by a number of vertical shutters, pivoted at top and bottom, and engaging by means of short arms or toothed wheels with a central wheel. The motion of the latter is produced by an electro-magnet, and an electric lamp of 100 candle power is used. A Morse instrument can be added, whereby the signals may be automatically recorded in the same way as in telegraphy. The action of the lantern is very satisfactory, and one has been used for several months on board the "Northumberland." It is hoped that by means of this lantern it may be possible to attain such speed in flash signaling that two parties may be able to interpret each other's signals, which, owing to the different rates at which signals are sent, is now found to be very difficult.

LEGAL NOTES.

NEW YORK SUBWAY LITIGATION.

The North American Underground Telegraph and Electric Company, which controls the Johnstone system of conduits or subways, brought suit recently against the Consolidated Telegraph and Electrical Subway Company and the New York Underground Telegraph Company to enforce a contract for the use of the Johnstone system and to recover $2,500,000 as damages on account of the failure of the subway company to keep the terms of the contract and put the system in operation. In this suit Judge Beach, in Supreme Court Chambers, was asked on August 7, by Charles W. Brooke, the counsel for the North American Underground Telegraph and Electric Company, to grant an injunction restraining the subway company from using or operating, laying or building any underground conduits in this city except under the Johnstone system.

Should an injunction of the extent asked for be granted, the city would again be placed in a peculiar position as regards its lighting by electricity, as comparatively only a small portion of the electrical lighting subways are equipped on the Johnstone system. Much confusion would also naturally result in respect to the subways for other wires. While reserving his decision, Judge Beach indicated as plainly as possible, without saying so, that he did not consider the case one in which an injunction should be granted.

ELECTRIC RAILROADS AND TELEPHONES AT ALBANY, N. Y.

Referee Lawson rendered a decision at Albany on Aug. 8, in the action of the Hudson River Telephone Company against the Watervliet Turnpike and Railroad Company for an injunction restraining the latter from operating its cars by the single trolley system, and for damages for impairment of its business by grounding its circuit. The referee holds that neither the application for an injunction nor for damages can hold, and dismisses the action. The railroad company has been restrained from operating its cars by electricity by temporary injunction pending the action. It will immediately bring suit for damages.

SOCIETY AND CLUB NOTES.

THE CAPE MAY MEETING.

Mr. Allen R. Foote, secretary of the National Electric Light Association, has issued a very handsome souvenir giving all the necessary details with regard to the arrangements for the Cape May meeting, which begins on August 19. The information given has already appeared in our columns, and Mr. Foote has put it together in admirable form.

In regard to the departure from New York, it may be stated that Messrs. John A. Seely and C. W. Price have, as a special committee, made plans for a party to leave this city for Cape May on Saturday, August 16, at 1:50 p. m. from the foot of Cortlandt street. This is an excellent idea, and all who wish to join the party should communicate with Mr. Seely, at 24 Cortlandt street.

OBITUARY.—W. H. ABEL.

William H. Abel, who had been prominently connected with the telegraph business almost from its beginning until forced by failing health to retire from active life, died on August 9. Mr. Abel was about fifty-four years of age. He was graduated from the College of the City of New York and for two years afterward acted as a tutor in the institution. He then gave up teaching for business, and entered the service of the American Telegraph Company, soon advancing to the position of auditor. When the American was finally merged into the Western Union Company he continued in the employ of that company. For a few years he acted as assistant secretary, and was then made chief auditor, holding that position until 1872, when poor health made it impossible for him to discharge the arduous duties of the office.

OBITUARY.—J. H. WADE.

Jephtha H. Wade, one of the oldest and wealthiest citizens of Cleveland, died there on August 9, after an illness of only a few days, aged seventy-nine years. Mr. Wade began life as a carpenter, was afterwards a daguerreotype artist, and then a telegraph operator. He built the first telegraph line west of Buffalo along the line of the Michigan Central Railroad. He next built the Wade lines to Ohio. He was the first president of the Pacific Telegraph Company, and the first president of the Western Union, which position he held till 1867. He has since been engaged in banking and other enterprises in Cleveland. He originated Lake View Cemetery where Garfield is buried, and also laid out and donated to the city Wade Park near the cemetery.

Mr. Wade invested in telegraphy at the right time and realized several million dollars from his investment. He was very charitable, among his gifts to the city of Cleveland being the park and an orphan asylum. Mr. Wade was a Democrat and had often been importuned to run for Congress, but always refused. His fortune is said to amount to $8,000,000.

In telegraphic circles, Mr. Wade will be remembered not only as being the first president of the Western Union Co., but as having been one of the chief promoters of the transcontinental lines, and of the projected line to Russia and Europe across the Pacific and Siberia. He showed himself in telegraphic work a man of great force and inventive ability.

INVENTORS' RECORD.

Patents issued August 5.

Alarms and Signals:—*Municipal Signal System*, B. J. Noyes, 433,485 and 433,486. *Municipal Signal Apparatus*, J. C. Wilson and B. J. Noyes, 433,504. *Light-Signal System*, J. C. Wilson, 433,505. *Electric Alarm Letter Box*, W. B. Detwiller, 433,560. *Electric Fire-Alarm and Night-Call*, C. J. Vining, 433,584. *Door-Bell*, C. A. Emme, 433,724.

Conductors, Conduits and Insulators:—*Insulating Material*, J. Fottrell, 433,893. *Method of Manufacturing Electric Conductors*, E. P. Warner, 433,917. *Joint for Electric Conductors*, G. L. Wiley, 433,920, 433,921 and 433,922.

Distribution:—*Electrical Transformer or Induction Device*, N. Tesla, 433,702. *Electric Current Controller*, M. O. Sargent, 433,744. *Current-Converting Apparatus*, C. Zipernowsky and M. Déri, 433,758.

Dynamos and Motors:—*Commutator for Dynamos*, J. W. Easton, 433,523. *Dynamo-Electric Machine*, C. F. Winkler, 433,557. *Alternating-Current Electro-Magnetic Motor*, N. Tesla, 433,700. *Alternating-Current Motor*, N. Tesla, 433,701. *Electro-Magnetic Motor*, N. Tesla, 433,703. *Induction-Motor*, C. J. Van Depoele, 433,834. *Electric-Motor Mechanism*, S. E. Mower and G. J. Spencer, 433,904.

Galvanic Battery:—*Galvanic Battery*, S. W. Maquay, 433,738.

Lamps and Appurtenances:—*Electrolier*, E. W. Little, 433,687. *Incandescent-Lamp Socket*, T. G. Roebuck, 433,698. *Electric Arc Lamp*, S. P. Parmly, 433,908. *Ceiling-Block for Incandescent Electric Lamps*, A. T. Tregwitha, 433,915.

Measurement:—*Electrical Measuring Instrument*, E. Weston, 433,637.

Metal Working:—*Electrical Soldering Iron*, C. E. Carpenter, 433,671.

Miscellaneous:—*Thermo-Electric Element*, E. N. Dickerson, 433,451. *Lightning Rod Tower*, I. F. Field, 433,459. *Electric Release for Target Traps*, L. I. True, 433,554. *Cleat for Electric Wires*, L. Furlong, 433,561. *Fusible Cut-Out*, W. J. Jenks, 433,682. *Fuse and Fuse-Block*, J. G. S. Cunnington, 433,770.

Railways and Appliances:—*Electric Railway*, A. A. Shore and W. Embley, 433,544. *Trolley for Electric-Motor Cars*, Forée Bain, 433,611. *Electric Circuit Coupling for Railway Trains*, W. P. Widdifield and A. H. Bowman, 433,706. *Trolley for Electric Street Cars*, F. C. Wheeler, 433,839. *Device for Unloading, Recharging and Reloading Electric Car Storage Batteries*, J. C. Chamberlain, 433,851. *Support for Electric Wires*, A. L. Hallbauer and E. L. Hiller, 433,896. *Electric-Railway-Conduit System*, M. Wheless. 433,918.

Telegraphs:—*Electrical Communication*, J. L. Cutler, 433,619. *Telegraph-Key*, J. B. Van Deusen, 433,835.

Telephones and Apparatus:—*Registering System for Telephone Exchanges*, J. C. Clark, 433,445. *Multiple Switch Board System*, E. P. Warner, 433,636.

EXPIRING ELECTRICAL PATENTS.

Reported by F. B. Brock, *Patent Attorney*, 639 *F street*, *Washington*, *D. C.*

Expired in April, 1890.

Annunciator, J. H. Corey, 137,422, April 1, 1873. *Battery*, R. M. Lockwood, 137,556. *Boat Steering Apparatus*, H. J. Smith, 137,574. *Relay and Sounder*, J. E. Smith, 137,730, April 8, 1873. *Connector*, F. Schurz, 137,801; T. Wishart, 137,810. *Electrical Tools and Machines*, Jacques, Oakley & Sterne, 137,875, April 15, 1873. *Underground Line*, E. H. Austin, 138,115, April 22, 1873. *Separator*, S. J. Peet, 138,276. *Induction Coil*, J. S. Camacho, 138,316. *Exploding Apparatus*, S. A. Briggs, 138,373. *Friction Generators*, F. H. Varley, 138,455, April 29, 1873.

Expired in May, 1890.

Insulator, Eby & Fenninger, 138,489; E. A. Merrill, 138,512. *Battery*, L. Bastet, 138,602. *Exploding Apparatus*, Mott & Gardiner, Jr., 138,679, May 6, 1873. *Electrical Machine or Tool*, B. Bevelander, 138,783. *Motor*, S. C. Carter, 138,855. *Printing Telegraph*, T. A. Edison, 138,869 and 138,870. *Telephonic Telegraph System*, R. Henning, 138,899. *Burglar Alarm*, H. E. Walter, 138,965, May 13, 1873. *Regulator*, H. A. Chapin, 138,993. *Printing Telegraph*, T. A. Edison, 139,128 and 139,129, May 20, 1873. *Duplex Telegraph*, G. D'Infreville, 139,302. *Railway Signal*, Digny, Lartigue & Forest, 139,376. *Insulator*, I. I. Tatoni, 139,436, May 27, 1873.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

THE CROSBY ELECTRIC CO.

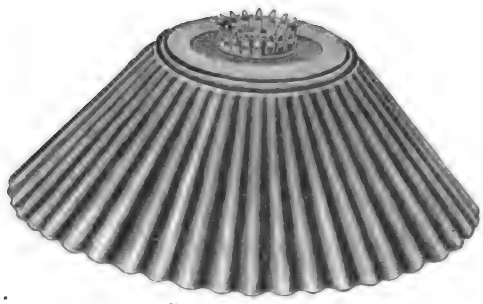
The above company has just issued the following circular from its headquarters in the Judge building, Fifth Avenue and Sixteenth street:—"The Crosby Electric Co. desires to notify its friends and the trade generally that it has purchased the Eclipse Electric Co., of New York City, with its business and stock on hand, together with the patents under which the Hussey Eclipse and the Duplex batteries are manufactured, and that, hereafter, the business and manufacture of said Eclipse Co. will be carried on under its management. It is prepared with a full line of everything necessary to the conduct of the business, and will guarantee strict attention and prompt delivery of all orders entrusted to it."

THE MAGNOLIA ANTI-FRICTION METAL.

We have had occasion more than once to remark upon the remarkable felicity of the Magnolia Anti-Friction Metal Co., of 74 Cortlandt street, in its choice of means for advertising its specialty. The judicious use of the advertising columns of the best technical journals, is supplemented from time to time by the publication of music, novelettes, pictures, etc., all bearing the name of Magnolia. The company has now struck the happy and rather original idea of issuing a calendar at midsummer, and we have received from it a handsome one which runs from July, 1890, to July, 1891. It is a beautiful piece of chromo-lithographic work in numerous colors, and gives views of the Brooklyn Bridge, the Statue of Liberty and the Eiffel Tower, with the chief data of the constructional features. The magnolia is a prominent object, and a cut is also shown of a bearing lined with the justly celebrated compound.

A NOVEL CONE SHADE.

Tin shades being cheap and unbreakable, there has always been a call for them from factories, mills, stores and other places where porcelain shades would prove too costly; the more so as the bright tin really reflects the light better than the expensive porcelain or glass shade. A year ago Mr. Geo. Cutter, now manager of the Great Western Electric Supply Co., went a step farther and designed a tin shade which required no shade holder.



TIN CONE SHADE FOR INCANDESCENTS.

The popularity of this "Combination Tin Shade," of which 20,000 are now in use, has now led the above firm to bring out a new pattern called "Cutter's Combination Cone Shade." As the cut shows, it is of a deep cone shape, making it well fitted for the use of book-keepers, draughtsmen, engravers and others who want the light concentrated on their work. As it fits the Thomson-Houston, Westinghouse and Sawyer-Man sockets directly, it is bound to hang square at all times. Its convenience, together with its cheapness, will probably cause it to be widely used for lights over desks and the like.

CONSOLIDATED FRUIT JAR CO.

The above company, of New Brunswick, N. J., and this city, have issued a very neat and effective calendar on decorated tin, the work of their own lithographing department. The company have a fine factory at New Brunswick, of which a view is shown on the first calendar sheet. They make a specialty of fuse wires, several samples of which are attached to the calendar. They also manufacture sheet metal novelties, brass castings, shade holders, battery screw tops, and spun and drawn work in all metals. They are equipped for electrical work of all kinds, and have had an extensive experience in the production of switches, sockets, cutouts, etc.

W. H. GORDON & CO.

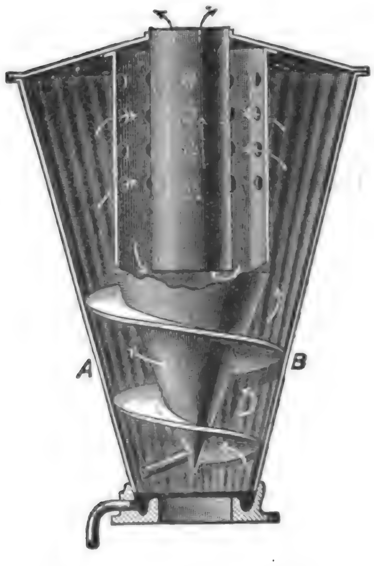
The above concern, of 115 Broadway, have, in addition to their regular large sales of electrical supplies, been extremely busy on Simplex wire for electric railway work. Mr. Gordon reports large sales within the last few days, aggregating not less than 50 miles. This wire enjoys a high reputation among electric railway people, for its qualities of insulation, etc., and a noteworthy feature of the orders is the promptness with which they are shipped.

THE JENNEY ELECTRIC MOTOR CO.

A very tasteful and interesting pamphlet on "Electric Motors and the Transmission of Power by Electricity" has been issued by the Jenney Electric Motor Co., of Indianapolis. It contains illustrations and descriptions of their motors; some excellent general remarks on the subject of power; data for power users, and a number of testimonials from people who have the motors in service.

THE NICETY OF MODERN STEAM-ENGINE APPLIANCES.

THE centrifugal exhaust pipe head, illustrated on this page, and for which Hine & Robertson, 45 Cortlandt streets, are agents, will be heartily welcomed by engineers who have gone through the more or less fruitless task of reducing the loss of thermal units set free in the boiler on their way to the cylinder. The oil fed into the cylinders of the engines, pumps, etc., passes out with the exhaust steam, which soon condenses and is deposited on the roofs, skylights and other places, injuring the roofs, coating the skylights, and in many cases dropping into the streets to the great annoyance of the



HEAD FOR EXHAUST STEAM.

public. The centrifugal exhaust head, illustrated, was brought out to remedy these troubles, and has met with such success that one company alone, the Sawyer-Man Electric Co., of N. Y., have seven on their plant, ranging in size from 12" down to 4". With a view of determining its efficiency, a test was made of a 12" for some weeks, and the very satisfactory results warranted them in purchasing six more. Unlike other heads, it has no diaphragms for the steam to strike against and create back pressure and a loud thumping noise, but is constructed with a spiral interior, giving to the steam on entering a centrifugal motion, forcing all oil and water against the sides, leaving the cleansed steam an opportunity to pass out through the perforated central pipe. The oil and water can be carried to any point through the small drip pipe at the bottom.

WESTINGHOUSE ALTERNATING PLANTS

An alternating current central station plant of incandescent electric lighting is about to be established at Waycross, Ga. The company organized there has just awarded the contract for the apparatus to the Westinghouse Electric Manufacturing Company. The plant will have a capacity of 750 lights, and the installation will be begun at one.

The Westinghouse Electric Manufacturing Company has obtained the contract for furnishing its alternating current apparatus to a company recently organized at Bryan, Tex. The plant will have a capacity of 500 lights.

Helena, Mon., as the capital of that youthful State of the Union, is showing all other cities and towns a good example by improving her illumination. A number of enterprising citizens who have established an electric light company are now erecting a plant both for arc and incandescent lighting with a capacity of fifteen hundred incandescent and forty arc lights. The plant will be furnished with the Westinghouse alternating current system.

FINE ELECTRICAL HOUSE WORK.

Mr. John Lewall, formerly with Pernaux & Co., has taken the quarters 6 East 17th street, lately occupied by that firm, and will there make a specialty of fine electrical work for churches, houses, theatres, stores, &c. He was in the service of the old firm as superintendent, and will maintain the reputation secured by the high quality of work done. Among the references are such concerns as Tiffany & Co., Eimer & Amend, J. D. Rockefeller, H. M. Flagler and others. Mr. Lewall has already been given the support of many old patrons.

FITCHBURG ENGINE CO.'S WORK.

The Fitchburg Steam Engine Co. write us as follows:—"We are very busy just now on contracts. We are fitting out the complete steam plant for the U. S. Government at Watervliet Arsenal, West Troy, N. Y.; are also building an engine for Farley Paper Co. at Erving, Mass.; shipping three large engines to Chicago; putting in engine and boiler for the Chas. Parker Co., Meriden, Conn.; also an engine for the Meriden Britannia Co.; putting in two engines for the Falulah Paper Co., Fitchburg, and one engine for the Fitchburg M'f'g. Co.; fitting out complete plant, engine, boiler, etc., in Shirley, Mass.; also building an engine for the Baldwinville Hospital, Mass., and one large compound engine for a Cold Storage Co.; one for the Real Estate Trust Co., Swanton, Vt.; putting in complete plant for the Electric Light Co., at Princeton, N. J.; also putting in a large plant with engines, boilers, etc., for the Clinton Electric Light Co., Clinton, Mass.; also complete plant at Kingston, Mass.; also two engines, boilers, etc. for a large paper mill in Delaware, besides a variety of other work. The company propose to double their capacity."

THE INTERIOR CONDUIT AND INSULATION CO.

A new catalogue and price list has just been issued by the above company, of 16 and 18 Broad street, fully illustrated and comprising many interesting details of the system and its method of introduction into public buildings and houses.

THE GREAT WESTERN ELECTRIC SUPPLY CO.

The Great Western Electric Supply Co., Chicago, have lately been receiving immense quantities of batteries, bells, annunciators and electric gas lighting apparatus, but, thanks to the well worked out methods of handling and storing goods, no annoyance or delay is caused. They also report heavy orders for their street-hood and porcelain cut-outs, besides the steady call for Simplex wire. They have already made some slight improvements in the Pattee Lamp Hour Recorder, and are filling orders with what is even a neater and more assuring form than that recently illustrated in our columns.

THE CONVENIENCE OF THE ELECTRIC MOTOR.

Mr. G. A. Redman, the superintendent of the Brush Electric Light Co. at Rochester, N. Y., writes us as follows: "We have installed two novel C. & C. motor services here lately. In one case a lady was very sick, and it was necessary to have some one fan her continuously. In order to meet the emergency a revolving fan was placed in her room run by the motor in the adjoining room. Thus she was able to get all the relief that fanning could give, without any fatigue to an attendant and without noise or discomfort. In the other case, a man was confined to his bed with a broken knee cap. A C. & C. motor with brass fan was placed in the corner of the room about 8 feet distant from the bed, with a cord run from the switch, so that the motor and fan could be switched on or off as desired. The sick man says that 'It is a darling,' and he would not part with it for any price"

THE EDISON GENERAL COMPANY'S DISTRICTS.

The following circular has been issued by Mr. James F. Kelly, of the wire department of the Edison Machine Works, with the approval of Vice-President Insull:—

We beg to inform you that the business of wire insulating heretofore carried on by the Edison Machine Works, has been transferred to the Edison General Electric Company, and will henceforth be conducted as a department of that company.

The Edison General Electric Company will have district offices in New York, Chicago, Denver, San Francisco, Portland, Oregon, New Orleans and Toronto. These districts will carry a comprehensive stock of the wires manufactured by the wire department. The districts named will supply the territory as indicated below:

Eastern District.—CHAS. D. SHAIN, *Manager*, 16 *Broad street, New York City*, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, New Jersey, Delaware, Maryland, Virginia and West Virginia.

Central District.—JOHN I. BEGGS, *Manager, Rialto Building, Chicago, Ills.*, North Dakota, South Dakota, Minnesota, Iowa, Missouri, Wisconsin, Illinois, Michigan, Indiana, Ohio and Kentucky.

Rocky Mountain District.—GEO. W. COSTER, *Manager, Masonic Building, cor. 16th and Welton streets, Denver, Colo.*, Kansas, Nebraska, Colorado, Wyoming, Montana, Utah and New Mexico.

Pacific Coast District.—W. S. HEGER, *Manager, Room* 6, *No.* 4 *Sutter street, San Francisco, Cal.*, California, Nevada and Arizona.

Pacific Northwest District.—S. Z. MITCHELL, *Manager, Portland, Ore.*, Oregon, Washington and Idaho.

Southern District.—O. T. CROSBY, *Manager, Cotton Exchange Building, New Orleans, La.*, Texas, Arkansas, Indian Territory, Louisiana, Mississippi, Tennessee, Alabama, North Carolina, South Carolina, Georgia and Florida.

Canadian District.—M. D BARR, *Manager, Bank of Commerce Building, Toronto, Ont.*, British Columbia, Northwest Territory (Athabasca, Alberta, Assiniboia and Saskatchewan), Manitoba, Ontario, Quebec, New Brunswick, Nova Scotia, Northeast Territory, Labrador, Newfoundland.

In all business matters with this company we request that you will communicate with the district office operating the territory in which your business is located.

C. & C. ELECTRIC MOTOR CO.

Messrs. E. G. McDougall and T. C. Cummings have assumed charge of the Chicago office of the C. & C. Electric Motor Co. Among the motors recently placed in their district are three of 10, 15 and 4 h. p., respectively, in the works of Cameron, Amberg & Co., the letter file makers, running the entire shops off the Edison circuit. There has also been an increase of a 15 h. p. C. & C. motor in the Chicago Auditorium.

THE NEW WOOD ARC SYSTEM.

Mr. H. C. Adams, the representative of the Fort Wayne Co., 115 Broadway, informs us that since October last they have sold no fewer than 9975 arc lamps of the new "Wood" system. This he naturally looks upon as a remarkable evidence of the popular approval with which the system is received.

ELECTRICAL CHAIN-HAULING IN A GERMAN COAL MINE.

An account of an electrical chain-hauling system in a coal mine near Beuthen, Silesia, Germany, is given in a recent issue of the *Zeitschrift fur das Berg-Hutten und Salinen-Wesen.*

According to the abstract given in the Excerpt Minutes of the Proceedings of the British Institution of Civil Engineers, the gallery in which chain-hauling is employed is about 500 yards long, having a double line of rails, of 25-inch gauge. The number of wagons dealt with per shift of ten hours is 800, weighing 440 tons.

In a continuation of the gallery is situated the driving drum, 6.55 feet in diameter, mounted on a vertical axis, around which the chain is wound one-and-a-half times. The chain having been conducted over a system of tightening pulleys, it is guided into the centre of each line of rails, one for the full and one for the empty wagons. At the opposite end of the gallery it passes around a vertical pulley 4.8 feet in diameter, equal to the distance from centre to centre of the rails. The bearings of this pulley rest in a channel iron so as to admit of tightening. The links of the chain are 0.80 inch in diameter, and it weighs 15 pounds to the yard. It rests on the top of the wagons, and is kept in that position by two vertical projecting pieces. The wagons are placed at intervals of 20 yards on the chain.

The current is supplied from the surface Schuckert dynamo, driven by a 60 horse-power twin-engine. Running at 680 revolutions per minute, this machine gives a current equal to 35.9 horse-power. The current is conducted down the shaft to the motor by a copper cable 320 yards in length, consisting of 19 strands of wire each 0.064 inch in diameter, giving a total metallic section of 0.059 square inch. The cable is insulated with gutta-percha and inclosed in a lead pipe. The motor in the mine is also a Schuckert machine, developing a maximum horse-power of 28.8 when running at 700 revolutions per minute. Between the motor and the chain drum intervenes a system of geared wheels, which

reduces the speed down to 10.5 revolutions per minute, giving the chain a velocity of 3.5 feet per second. The dynamo and the motor are both provided with ampere meters having a range of 80 amperes and resistance coils, by means of which starting is effected gradually, and the current afterwards maintained at the working rate.

SIR WILLIAM THOMSON'S COMPASSES.

The House of Lords has given judgment in the appeal by Mr. Francis M. Moore, nautical instrument maker in Dublin and Belfast, against a judgment of the Irish Courts that he had infringed the patent compasses of Sir William Thomson. The Attorney-General, who appealed on behalf of Sir William Thomson, contended that the appellant's second compass card was the same as the respondent's, except that, in place of silk threads connecting the boss with the rim, strips of metal were used, and except also that the magnetic needles were suspended by strips of metal instead of by silk threads, and in vertical and not in horizontal planes. The substitution, however, of metal strips for silk threads, and of vertical for horizontal planes, made no difference in the action of the compass card, and were mere mechanical equivalents for the method of connection of the rim and body and suspension and disposition of the needles described in the respondent's amended specification and drawings, and that the appellant's second compass card, like the respondent's compass card, had very small fractional error, small magnetic needles, and a moment of inertia such as to give it a very long period of free oscillation. Their Lordships gave judgment against the appellant, on the ground that Mr. Moore's compass was substantially a copy of Sir William Thomson's, and that the points of difference between them were of a subsidiary character, and not in any manner essential to the peculiar construction claimed. The appellant had no right to use the respondent's combination for the purpose of improving upon it, or the reverse, as the case might be. The appeal was accordingly dismissed, with costs.

AN ELECTRICAL EXHIBITION FOR PORTLAND, ORE.

The prosperous and growing city of Portland has a fine exhibition building, and now proposes to use it for an electrical exposition. Mr. Z. L. Mitchell, while in the East recently, made arrangements with Mr. Luther Stieringer, who is to furnish plans, etc., and there is already every promise of a brilliant success. We have had an opportunity of seeing the plans, which we find include a number of lighting and structural effects far surpassing those which entranced New Yorkers recently at the Lenox Lyceum. The exhibition will begin early in September.

AN IMPORTANT PATENT SALE.

The United States patents, covering the Widdefield-Bowman automatic electric brake system for freight trains, covered also by patents in Canada, Great Britain, India, Russia, Italy, Spain, Germany, Austria-Hungary and Belgium, were recently sold to the Westinghouse Air Brake Co., of Pittsburgh, for a large amount in cash and royalty. The system, and a test of the same on the Lehigh Valley Railroad, were fully described in THE ELECTRICAL ENGINEER in 1889. Edward P. Thompson, of New York, was interested in the patents as one of the selling agents, and served as attorney in obtaining the U. S. and foreign patents.

PATTISON BROS., ELECTRICAL ENGINEERS AND CONTRACTORS

A new contracting and engineering firm, under the style of Pattison Bros., has been formed at 135-137 Broadway, by Mr. Charles E. Pattison and Mr. Frank A. Pattison, who are prepared to submit and carry out plans on all classes of lighting, power and electric railway work. Mr. C. E. Pattison was for some time associated with Mr. J. H. Vail when the latter was Chief Engineer of the Edison Company, and proved an apt pupil in that excellent school. He did a large amount of work on the big uptown Edison stations, and was also engaged in work in Boston as well as out West. In Boston he put in the underground service of the second Edison district. He was also at one time connected with the old Bergmann Company as electrician. Latterly he was sent to the Argentine Republic to install plants there, and returned only a month or two ago. His brother, Mr. F. A. Pattison, has had charge of the Edison station in New Orleans for the last two years, and is generally familiar with the whole routine of lighting work. The young firm start out, therefore, with ample experience, and may be safely entrusted with work of the greatest magnitude and importance.

NEW ENGLAND TRADE NOTES.

THE JOHN S. PRATT COMPANY, OF HARTFORD, have just built a new factory for the manufacture of vulcabeston, which has been rapidly increasing in favor among electricians for all insulating purposes. The new factory will consist of two buildings, one 100 feet by 40 feet, two stories high, and the other 80 feet by 40 feet, three stories high. Their present factory occupies part of the buildings of the Pratt & Cady Company, and for some time they have been very much cramped owing to the increasing volume of their business, but they will soon have ample facilities for a very large product.

THE PERKINS ELECTRIC LAMP COMPANY, whose headquarters have hitherto been at Hartford, Conn., have removed their office to Manchester, Conn., where their factory is situated. They have increased their capacity now to 4500 lamps per day, and will commence turning out that number this week. Their previous output was 2000 lamps per day, but Mr. J. J. Gates, the secretary of the company, informs me that they were totally unable to keep up with their orders on that number. With the office now at Manchester, they will be better able to handle their rapidly increasing business.

THE WAINWRIGHT MANUFACTURING COMPANY, OF MASSACHUSETTS, have recently increased their business to such an extent that they have found it necessary to increase their manufacturing facilities. They have made arrangements with the Taunton Locomotive Manufacturing Company, at Taunton, Mass., whereby they will materially aid in the manufacture of the well-known Wainwright heaters, condensers, and expansion joints, and will enable the Wainwright Company to carry a large stock of goods, which they have been unable to do owing to an unprecedented demand. Among their recent sales to electric companies are: 800 horse-power heater to the Waltham Gas and Electric Light Company, Waltham, Mass.; this is the third heater supplied to this company. They have also sold a 600 horse-power heater for the electric light plant of the American Waltham Watch Company's factory at Waltham, Mass.

WESTERN TRADE NOTES.

MR. THOS. GRIER, of the National Engineering Bureau, Chicago, has just returned from a trip East, where he has been taking a short vacation. Mr. James Lounsbury, of the Bureau, left Saturday for the East on a short trip to Montreal, Boston and Hartford, where he will combine business and pleasure. He expects to be gone about two weeks.

THE ILLINOIS ELECTRIC MATERIAL CO. are filling numerous orders for poles and pole line supplies and Bishop white core wire and their other specialties. Mr. H. S. Winston, the president and treasurer, has recently made a number of short but very successful business trips, returning from all with his pockets well lined with orders.

J. LANG & CO., 44 Michigan street, the well-known manufacturers of the Lang & Andrew switches, are now making some of these switches for very heavy currents. The workmanship throughout their switches is of the very best, and the copper employed in their construction of the highest conductivity and greatest durability. Heating or arcing in their switches, either large or small, is unknown. They are also just bringing out some very highest class switches for alternating work which contain special features peculiarly adapted for work of this kind.

THE WESTERN POWER CONSTRUCTION CO., 144 Adams street, are getting lots of business and find it difficult to keep pace with their construction work and their large orders for the famous McIntosh & Seymour engines, for which they are the sole Western agents. Mr. Wilson, of the company, has just returned from a flying trip East to the factory at Auburn, where he has been making arrangements for their engine orders to be got out with the greatest possible expedition. Mr. W. P. Adams, the general manager, who is well known and liked all over the country, is flying around all the time and continually catching new business.

THE ELECTRIC MERCHANDISE CO. are receiving inquiries and orders for their electric street railway supplies, to which line they devote their undivided attention, from street railway men all over the country; and although but recently in the field, they are doing a very large business. Supplies of the very best and latest designs for all classes of this work, irrespective of system, can be obtained from this company, and they carry at all times a most complete stock ready for immediate shipment. A fine line of handsome samples of all their goods is to be seen at their store at 11 E. Adams street, and will well repay the electric railway man for a careful inspection.

WM. BARAGWANATH & SON, 48-52 W. Division street, manufacturers of boilers, feed water heaters and purifiers, are at present building a heater which, as compared with those of ordinary size, is a veritable whale. Its dimensions are 5 feet by 22 feet, and when complete it will weigh about 11 tons. In its construction about 4 tons of seamless brass tubing have been employed. Its exhaust ports are 24 inches and its feed pipes 6 inches. Figuring on their basis of rating of one horse-power per foot of heating surface, it will boil the water for 2,110 horse-power capacity of boilers. This enormous heater is being manufactured for the Chicago Edison Company. They are very busy constructing a number of ordinary sized feed water heaters and their other specialties.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, AUGUST 20, 1890. No. 120

Great as are the triumphs of the present century, we may well believe they are but a forecast of what discovery and invention have in store for mankind.—Lord Rayleigh.

THE ELECTRIC LIGHT AND POWER INDUSTRY.

TEN years ago the electric light was practically and commercially a thing little known in this country. To-day a traveler can go from one end of the land to the other and night after night depend upon no other light than that of electric lamps. In fact there are many places, especially in the South and West, where he will have no choice, but finds electricity to be the only illuminant. This, however, he does not regret. Why should he?

Few industries have sprung into existence attended by such wild speculation as that which beset electric lighting in its early days. The poet with his eye rolling in a fine frenzy was tame compared with some of the geniuses who aspired to fame and fortune as electric light inventors, ten years ago; and the fools who stood ready to follow such will-o'-the-wisps were thicker than August mosquitoes in the Jersey meadows. As a result there was panic and disaster, and for not a short space of time the electric light bore a bad name as an enterprise and a worse repute as an investment. Then came the period of slow revival, patient effort, persistent pushing, and a keen realization of the fact that to succeed the new industry must be based on sound engineering principles and be compacted by honest work from the foundation up. The result is that to-day the industry, product as it is of one decade, compares favorably in every respect with others that have taken fifty years to reach their present maturity and magnitude.

Statistics brought down to the close of the half year ending July, show that the United States has about 1,400 central stations, operating nearly 150,000 arcs and over a million and a half incandescents. The engine capacity of these stations reaches 356,000 h. p.; the boiler capacity is certainly 10 per cent. more. These companies represent a capital of nearly $120,000,000. Yet these figures tell only half the story, for all the incandescent and arc lighting in over 4000 isolated plants has to be added. The gross sum of $300,000,000 would about cover the investment, or a steady expenditure of $30,000,000 annually for ten years. Large as these totals may seem, they are but initial, for the tendency everywhere is to the installation of larger plants, and the necessary capitalization on a larger basis.

If the industry stopped short at lighting it would still be worthy of admiration as one evidence of American enterprise and inventive skill; but it has already annexed to itself and exploited the vast department of electric power, It is unquestionably this field that will see the greatest development during 1890-1900. The electric transportation industry even now segregates itself, but the industrial service of electric power will remain closely allied to that of electric lighting. Already we see the local lighting companies in leading cities like New York, Boston, Chicago, Brooklyn, Philadelphia, Baltimore, Detroit, Cincinnati, San Francisco and others furnishing daily hundreds of horse power of electric current for the most diverse purposes. In New York alone, the delivery of electric power in small units runs from 1200 to 1500 h. p., and is likely to be doubled within a year.

Evidently the situation is one that should fill electrical engineers with courage and hopefulness, and it furnishes the best of reasons for such meetings as that which will be held this week at Cape May. New questions and problems develop daily, and difficulties of all kinds have to be met. Each man has his own experience and his own interpretation of it; but it is not until all have come together in brotherly intercourse and interchange that we have an authoritative utterance, a successful industry and a perfected art.

"Let us rest and be thankful" said an optimistic English statesman as he surveyed the past and the road by which his party had reached its vantage ground. The sentiment is a happy one, but perhaps they of us who are busy in the work of light and power can hardly adopt it to the full. We have good cause to be thankful, but with all the cares and responsibilities of the young and growing industry upon us, we cannot rest yet—except at Cape May.

THE PRODUCTION OF HEAT FROM ELECTRICITY.

IN a recent note appearing in these columns attention was drawn to the existing troubles encountered in the steam distribution system in this city, and the fact dwelt on that the necessity for the existence of such systems was now, to a large extent, a thing of the past, since the introduction of the electric motor solved the question of power distribution in an ideal manner. It was pointed out incidentally at the same time that the only other object fulfilled by the steam distribution, that of heating buildings, was also attracting the notice of far sighted men, and was a point yet to be dealt with by electrical inventors and engineers. While not objecting to the economy attainable by the electric distribution of power over steam, our excellent contemporary, the *Engineering News*, takes us to task for advancing, as it claims, the "electrical radiator" idea, notwithstanding its evident inferiority when compared with the

direct distribution of steam for heating. In proof of its assertion, it enters into a "heat unit" comparison of the two in which it is shown that, as a heat distributor, the efficiency of the electric system is to that of the steam system as 1 is to 11. The calculations given by our contemporary are substantially correct, although no allowance is made for condensation in the street distributing pipes; and hence deserve further notice at our hands in order to make clearer the exact position of electric heating. We think that this can best be shown by drawing a parallel of the course taken by the public with reference to electric lighting. Our contemporary very aptly remarks that the commercial test is the one by which an invention must stand or fall, and it is this very test which has brought electric lighting to the prominent, and we may safely add, dominant, position it occupies at the present time. We need only to recall the scepticism generally expressed by scientific men as to the impossibility of solving the incandescent electric light problem in an economical manner, while not a few among them actually declared impossible what is now of daily occurrence. We need not here enter into the oft recited reasons which have brought about these results, but wish merely to lay stress upon the fact that they still hold true and that the public is constantly demanding improvements in its conveniences and that it is willing to pay liberally for them, while, actually, it pays less and less all the time. We think there can be no question as to the superiority in every respect of electric heating over that of steam, aside from the bare question of economy of generation, and this once demonstrated, all the experience of the past points to the commercial success of electric heating. Our contemporary has taken as an example a case in which a building requires 50 tons of coal per year for its heating alone, and which is, therefore, of sufficient magnitude to warrant the introduction of its own steam heating plant. But it is to the individual householder, burning probably not more than from 15 to 25 tons of coal per year, for all purposes, and not infrequently in a grossly wasteful furnace, that the electric method will appeal most strongly, just as in the distribution of electric power the smaller consumer finds it more economical to employ an electric motor deriving current from a central station, than to generate power directly on the premises.

So far as car heating is concerned, experience has shown that an electric street car can be comfortably heated by the expenditure of 1 h. p. of electric energy. The adoption of the electric heater saves a man at the car house, whose sole duty it has been to look after the stoves and whose wages will buy a considerable amount of coal. The electric heaters do not reduce the seating capacity of the car, as do the coal stoves; and, more important than all, the car is kept clean and free from coal dust, cinders, etc.

Above all, however, we must not lose sight of the fact that the near future may, and will, bring forth some practical method of generating electricity direct from fuel without the intermediary of the steam engine and dynamo, in which case the calculated difference in direct economy between the two systems would largely, if not entirely, disappear. We believe that enough has been said to have justified us in the use of the phrase to which exception has been taken. While fully aware of the factors at present involved in the problem, we can still conscientiously encourage the "electrical radiator" idea. We propose to do so in season and out, as part of our journalistic duty. Nor shall we fail to derive encouragement and argument from the fact that electric heating apparatus is already coming into use, and for various purposes has been found extremely convenient, economical and successful. Apparatus that heats cars, keeps flatirons at the right temperature, cooks griddle cakes, boils eggs, fries bacon, broils steaks, bakes bread and warms beds has certainly reached the practical stage.

IMPROVEMENT IN ARC CARBONS.

Next to the mechanism itself of an arc lamp, the carbon employed is the factor upon which, to a large extent, both the brilliancy and the steadiness of the arc depend. This was recognized very early in the art, and the experiments which have been made to improve arc carbons, would, if collated, fill volumes. Unlike other work in the electrical field, its progress is not closely traceable by the records of the Patent Office, for nearly every experimenter in this direction has chosen to keep his methods and the nature of the ingredients employed to himself. The general nature of the materials used is, of course, well known, consisting for the larger part, at least so far as this country is concerned, in petroleum coke, to which hydrocarbon binding or cementing material is added, such as tar. In Europe gas coke still continues to be the principal ingredient. Attempts were early made, however, to increase the light-giving power of the carbon points by the addition to the carbon mixture of some of the earthy salts, such as magnesium and calcium, which give out a brilliant white light when heated. These additions, however, have invariably introduced accompanying troubles, so that up to the present the pure carbon may be said to still hold the field exclusively. Any dispute which may still exist regarding the nature of carbons has now narrowed itself down to a question of the relative superiority of "forced" or "molded" carbons. But if we are to credit what certainly seem to be well founded statements, an improvement in arc carbons has recently been effected which cannot fail to have its effect on arc lighting generally. This improvement, due to a Mr. Saunderson, as described more fully elsewhere in this issue, consists in feeding into the arc a hydrocarbon oil, which is acted upon and volatilized, and by which the illumination is increased nearly two-fold. The employment of a hydrocarbon as an increaser of the light-giving power for a given consumption of electrical energy certainly removes the objection against the earthy salts. If the new carbons can be furnished at a reasonable cost, such as is claimed to be the case, the slight increase in the rate of consumption during burning ought not to stand in the way of its introduction. As yet the experiments with the new carbon have only been carried out on a small scale, and it is to be hoped that more extended use will warrant the good reports now heard. A thorough investigation of the phenomena accompanying the operation would prove of considerable interest, and we trust the subject will be taken up in a manner similar to the investigation recently submitted by Mr. Louis B. Marks to the American Institute of Electrical Engineers.

LIGHTING THE BRIDEWELL PRISON, CHICAGO.

The Western Electric Company has just finished the installation of an incandescent electric light plant at the House of Correction, Chicago, of about 1,100 lamps. The requirements of this plant are somewhat different from those usually found in electric installations, inasmuch as the institution in which it is placed is a prison, and not only must malicious interference on the part of the prisoners with the apparatus be provided for, but, in dealing with brick walls and steel plates almost entirely, difficulties in the way of construction have been met and successfully overcome that are not usual to such a degree in work of this kind.

Our engraving, Fig. 2, shows a corridor in one of the cell houses of the institution—there being three such cell houses in all. The walls are of brick, 30 feet high, and covered by an iron ceiling. The cells rise four tiers in height, with 40 cells in each tier, and are built of steel plates bolted together, each tier being provided with a gallery of steel with an iron railing running entirely around it. No lights are placed in the cells, as being too exposed to the destructive instincts of the occupants; but the cells are lighted from incandescent lamps placed on the walls in front of the cell doors in vertical rows of four each, the uppermost lamps being 15 inches from the ceiling, and the lowest eight feet from the floor.

To reach these lamps the iron ceiling was pierced and the wires were brought down the walls from above so that they are entirely out of reach of the prisoners.

There are 56 lamps on each wall opposite the cells, and these are under the immediate control of the keeper by means of a single switch in a locked box outside of the cell house door, all out of reach of the prisoners. At each corner of the galleries on each tier is a single lamp at each end, giving the keeper a clear view of its entire length and of the cell doors at all hours of the night, and any movement of the doors, or the presence of any person on the galleries, could be instantly detected.

The wires to the gallery lamps are brought from the iron ceiling through iron pipes to the columns supporting the galleries, and thence distributed at the proper height. These lights are not operated by the switch which controls the wall lights, and which are extinguished at eight o'clock, but burn during the night. In addition, there are the superintendent's residence, the guards' quarters and the kitchens, etc., which are lighted in the usual way. Two Western Electric incandescent dynamos furnish current for the lights, one of 800 light capacity, and one of 300, at 110 volts. The dynamo room is illustrated in the engraving, Fig. 1. The switch-board is so arranged that the dynamos may be operated separately, each with its own load, or singly upon the entire system, or in multiple with the entire load. The dynamos are driven by two Ball engines of 70 and 30 h. p., respectively.

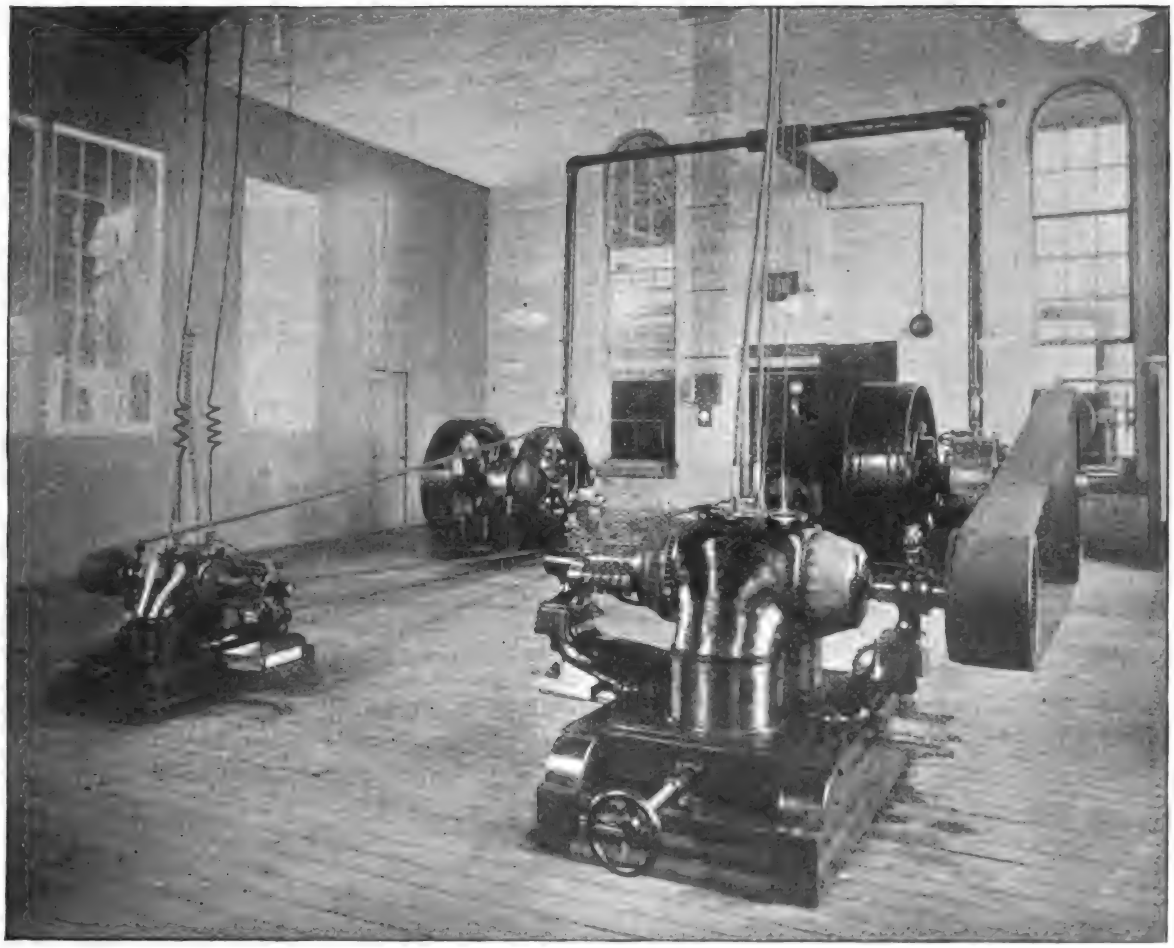

Fig. 1.—Dynamo Room at the Bridewell Prison, Chicago.

Throughout the entire system there is used the Western Electric double-pole multiple cut-out, recently described in these pages, and by means of which lamp circuits may be tested and fuse strips inserted while the current is on the system.

The system is operated throughout the night, and entire dependence is placed upon it for the lighting of the prison.

The illustration, Fig. 2, gives an excellent idea of the manner in which the scheme of illumination above described is carried out. As will be seen, the lamps are placed upon the walls and shine into the cells at a safe distance, being entirely beyond the reach of the prisoners, yet under direct

and immediate control of the keeper, who also has everything in clear view. The advantages gained are such that we need not wonder at the growing favor in which electrical illumination is held for lighting prisons. Another feature, incidental but none the less noteworthy, is the improvement in hygienic conditions obtained with the electric light, whose purity and cheerfulness have been observed to have a marked influence for good on the spirits of those held in durance that ceases to be vile.

A CONTINUOUS CURRENT TRANSFORMER.[1]

THE continuous current transformer at the Chelsea Company's station at Draycott Place, in London, resembles in design an inverted Elwell-Parker dynamo. The armature is of the drum type, the two windings being upon the same core, and a commutator for each is arranged at opposite ends of the armature. The machine has been constructed by the Electric Construction Corporation (Limited), and has given very satisfactory results during the time it has been under test. The output for which the machine is intended is 33,500 watts, and the speed 1,000 revolutions per minute. There is obviously a necessity for extra precaution in insulating the high and low tension circuits from each other in the armature of the transformer, on account of the mechanical stress.

The method adopted by the designers of the machine has been to wind up the primary into thin ebonite troughs, which are laid along on the surface of the armature. This has proved efficient so far. The insulation resistances, which have been steadily rising since the commencement of the tests, is at the time of writing as follows :—

Between the windings, . .	17 megohms.
" the thick wire and frame of machine, . .	7.5 "
" the thin wire and frame of machine, . .	9 "

A test has recently been made of the performance of the transformer, the readings and the results of which are given in the table below :

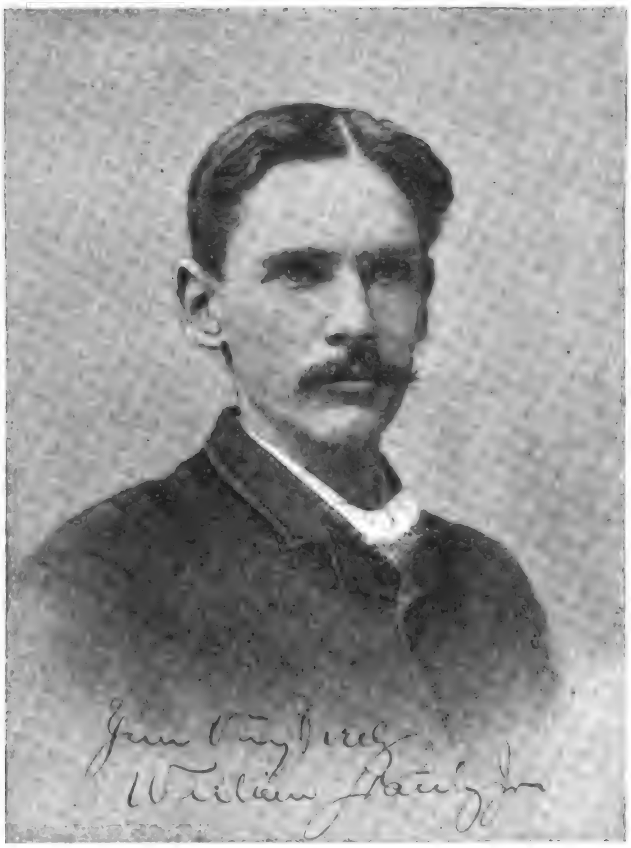
1. London *Electrician*.

ELECTRICAL ENGINEERS.

WILLIAM STANLEY, JR.

Among the young men who have contributed to the development of electrical science in its application of electricity, as an agent of light and power, few have done better work than the subject of this article.

Born in 1858, not yet 32 years old, Mr. Stanley has already a substantial reputation as an inventor and designer of electrical machinery. His tastes were early manifested. When a small boy he had a carpenter's bench and chest of tools and a lathe in his father's attic, and took a single course of drawing lessons; and, with another lad, built and worked a line of telegraph between their houses. Through one of his tutors he became interested in chemistry and in nickel plating by electricity. Still it was not realized that he had a pronounced bent for invention, and he was sent to the Classical School at Easthampton, where he fitted for college. He matriculated as a student at Yale, in 1875, when 17 years of age. Having a strong desire, however, for more active practical work than classical studies afforded, although standing high in his class, he abandoned his college course, and became engaged in a successful nickel plating house in New York city, where he worked with his own hands until he had learned the art practically. He then concluded to cast his fortune in the new born electric light industry. He sold out his interest in his business and engaged as a common laborer in the shops of the United States Electric Light Company, for seven dollars a week. An incident illustrative of his whole life and character soon took him from the workshop into the laboratory and brought him to the notice of the electrician of the company. He learned that Mr. Hiram S. Maxim desired to secure for laboratory use some paper of a special kind for which his agents had been vainly searching among the dealers in New York. Mr. Stanley went to Dalton, Mass., obtained a sample at his own expense, and a few days afterward handed the desired article to Mr. Maxim, much to that gentleman's surprise and gratification.



William Stanley, Jr.

Mr. Stanley was immediately transferred to the laboratory, in which he remained until he voluntarily left the company about 1883, when he was offered and accepted the position of superintendent of the American Electric Co. This position he left to take charge of the Boston Laboratory of the Swan Electric Light Co. While connected with the Swan company, Mr. Stanley made the acquaintance of Mr. George Westinghouse, Jr., an acquaintance which resulted in the subsequent purchase by Mr. Westinghouse of all the inventions theretofore made by Mr. Stanley, upon which basis was founded the now well-known Westinghouse Electric Company, with which Mr. Stanley has been continuously connected since its organization.

Besides doing a large amount of valuable work in designing electrical apparatus and in similar directions, Mr. Stanley has been fertile in inventions, without a mention of some of which any sketch of his life would be incomplete.

In 1883 Mr. Stanley constructed a welding machine with which he electrically welded the terminals of a storage battery he was then constructing to the grid of the plate. He also suggested to the plumbers of Englewood, N. J., that they adopt this process in joining iron and lead pipe for house plumbing.

In 1881 he devised an improved method of exhausting incandescent lamp bulbs; exhausting by a mercurial pump into a vacuum produced by a mechanical pump, thus increasing not only the rapidity with which the pumps can be worked, but also the degree of vacuity obtainable.

Together with Mr. E. P. Thompson, Mr. Stanley devised the method of treating silk thread for the manufacture of incandescent lamp filaments, now in use by the Sawyer-Man Company. Previously the manufacture of carbon filaments from materials containing nitrogen compounds, such as silk, had been difficult, owing to the fact that the silk would melt when heated below the carbonizing temperature. By removing a portion of the nitrogen compounds from the thread they found that a filament was produced having a condition resembling unstable equilibrium of the atoms, which could be carbonized at a temperature as low as 125° F. Some of these silk carbon lamps at the Electrical Exhibition, at Philadelphia in 1884, showed, during life, the highest efficiency of any lamps exhibited.

During the year 1884 and a part of 1885 Mr. Stanley was engaged in experimental work in the shops of the Union Switch and Signal Company, Pittsburgh. In October, 1885, he removed on account of his health to Great Barrington, Mass., where he built and equipped a complete laboratory for experimental work. During these years he first designed the form of induction coil, or, as first called by him "converter," of the type now largely used in this country. He also developed the self-regulating system of alternate current distribution now in use by the Westinghouse Electric Co. Having observed some apparatus of the Gaulard & Gibbs system, imported by the Westinghouse Co. in the spring of 1885, he ascertained its defects, and determined that the best system of distribution by converters involved the use of an alternate current generator, giving a current of constant potential and high E. M. F. with converters connected in multiple arc, the converters being constructed in such a way that practically no current should traverse the primary circuit when the secondary circuit was open, and also so organized as to allow current to flow through the primary circuit in direct proportion to the current abstracted from the secondary circuit, to the end that the current produced by the dynamo should always be proportionate, and equal, to the current used in the consumption circuit. In order to demonstrate the practicability of his system, Mr. Stanley equipped and put in operation in the spring of 1886, in the village of Great Barrington, a practically operative lighting plant, which may be fairly said to have been the first successful alter-

nate current electric lighting plant in this country. All the apparatus was made at his laboratory in Great Barrington, and though crude in finish produced good results. The system was at once adopted by the Westinghouse Company, the first commercial plant being put in operation at Buffalo, N. Y. on Thanksgiving Day, 1886.

In connection with the operation of the Great Barrington plant, Mr. Stanley constructed a regulator for the dynamo, the mechanism of which was controlled by a repulsion dynamometer, operating upon the principle of repulsion explained by Prof. Elihu Thomson in his lectures, and explained and illustrated at length in a recent article by Prof. Fleming. This dynamometer was the first piece of apparatus constructed operating upon this principle.

Perhaps no one of Mr. Stanley's inventions has excited more general interest from both a scientific and a practical point of view than his self-regulating constant current dynamo especially adapted for alternating current arc light systems. In this machine the regulative effects are produced, not by any pronounced departure in constructive details from well known forms of dynamos, but by such proportioning of the parts that, whatever the resistance in the external circuit, an electromotive force will be developed sufficient to maintain an approximately constant current value. One of the fundamental principles underlying the operation of the machine is that the magnetic conductivity of the magnetic circuit provided for the field lines of force, and consequently the effective value of the field lines of force, is varied by opposing the magnetic potential of the field with a counter magnetic potential, due to the armature current, and varying with variations in the resistance of the work circuit.

The fruits of Mr. Stanley's restless energy in the field of invention have been so numerous that full mention even of those of considerable importance is impossible here. While he seems sometimes to solve electrical problems almost intuitively, his success in this field of work is chiefly due to his power of intense and energetic application to the work in hand, a quality which has won for him a degree of success seldom secured by so young a man.

AN ELECTRIC COAL MINING EQUIPMENT.

In our last issue we gave a description of the highly interesting electric plant recently put in operation in the First Pool Monongahela Gas Coal Co.'s mines at Willock Station, Pa. This electric equipment was designed and installed by the Mill and Mine Electric Equipment Co., of Pittsburgh, Pa., under the supervision of Mr. W. A. Giles general manager and electrical engineer for the company, to whom we are indebted for further interesting particulars regarding the plant.

The power plant consists of two 12x20 Carter engines and one 30 h. p. 3-wire, 4-pole Westinghouse self-exciting, alternating generator. All switches, meters, etc., are mounted on a switchboard in most convenient location to be easily handled. The voltage on the main line is about 300 volts. Inserted in the main line at convenient locations are several specially designed mine switches with safety catch attachments, and all switches used in these mines are so designed that no metallic part is exposed. All wood work of the switches is made thoroughly waterproof and the switch handle is detachable and carried by the motor man. This prevents the switch being tampered with by meddlesome persons.

The wire used in these mines is all of the Clark rubber-covered special mine finish type, and all wire connections are made with McIntire connectors. All wood work is made waterproof with P. & B. compound. The coal cutting motors in the rooms are connected to the main line by a specially made insulated flexible cable, which can be coiled on a special reel and taken to another room in a few minutes. This cable when in use is supported by glass hook insulators made for this purpose.

Six "Hercules" coal mining machines, with 3 h. p. Tesla motors mounted thereon, as shown in the engraving, Fig. 2, are now in operation in these mines. The machine and motor complete weighs about 1,000 pounds and is easily handled and shifted from room to room by one man. A specially designed truck is used in conveying machine from one room to another. These machines, by means of a set of gang bits or augers, make an undercut 3 inches high, 36 inches wide by 42 inches deep. One man with this machine will average 40 cuts, or about 43 tons of clean cut coal in 10 hours. This is equal to the product of 12 to 14 pick miners.

The ventilating outfit in this mine consists of a 12 ft. Pollock fan, with a capacity of 30,000 cubic feet per minute. It is situated at the bottom of a shaft 75 feet deep, and is so arranged that the fan can be changed from an exhaust to a blower in 5 minutes. This fan is also run with a 3 h. p. Tesla motor.

The pumping outfit consists of a centrifugal pump of a capacity of 90 gallons per minute, mounted on the same truck with 3 h. p. Tesla motor and connected to the same by means of a belt, as shown in Fig. 1. This pump and motor can be taken to any part of mine and connected to the power line in a few minutes.

These mines have an incandescent electric light plant, consisting of a United States 300-volt, automatic incandescent dynamo, running 150 Sawyer-Man lamps, mounted in special waterproof mine sockets with rubber insulating joints. These lamps are connected in loops of three in series across the main circuit, and placed along the main entry at a distance of 80 to 90 feet, and three 16 c. p. lamps are placed in each room. This gives perfectly satisfactory illumination and demonstrates the great importance of better light in coal mines.

The following record shows the large amount of work which can be accomplished with but a few machines. Indeed it has been demonstrated that they can work faster than the rooms can be cleaned up of the coal which is brought down. The record, which is taken from the company's books, extends from July 1 to Aug. 8, and each cut represents about $1\frac{1}{10}$ ton of nut coal.

The Mill and Mine Electric Equipment Co. is now putting

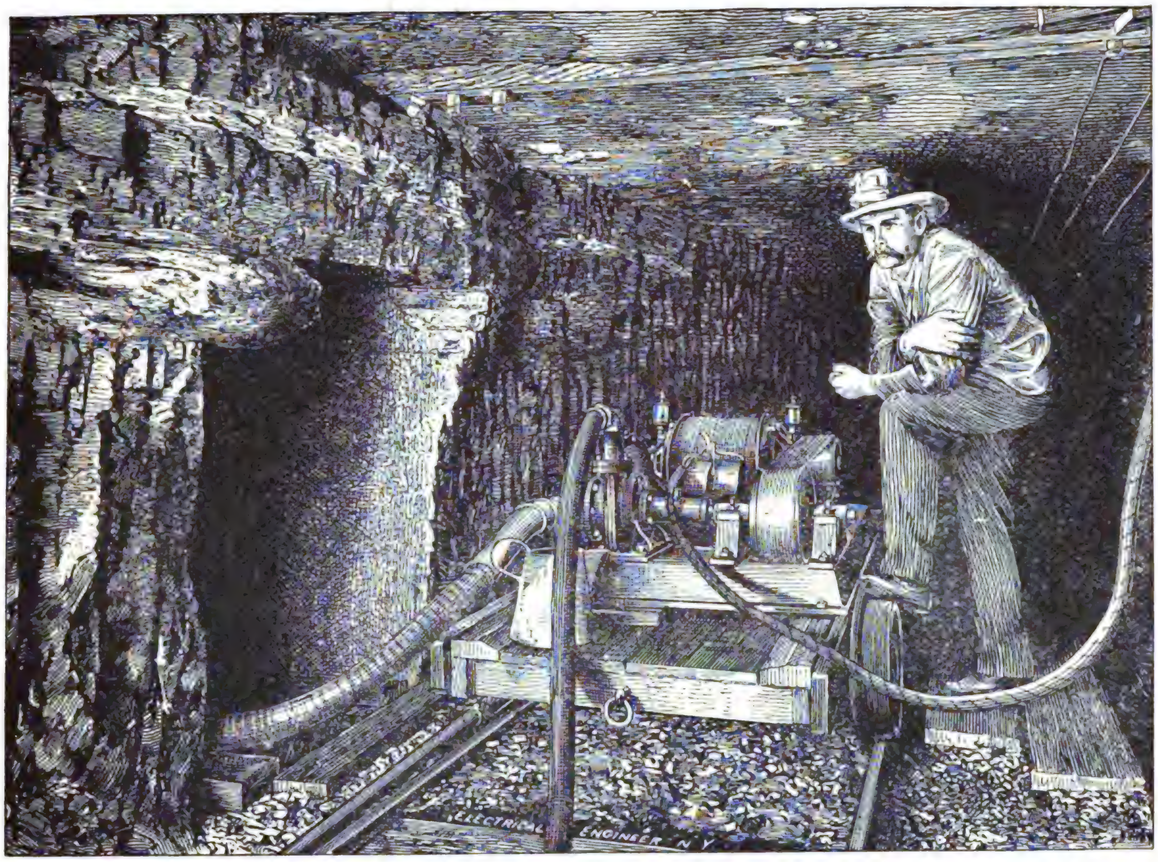

FIG. 1.—TESLA MOTOR DRIVING CENTRIFUGAL PUMP, WILLOCK COAL MINE.

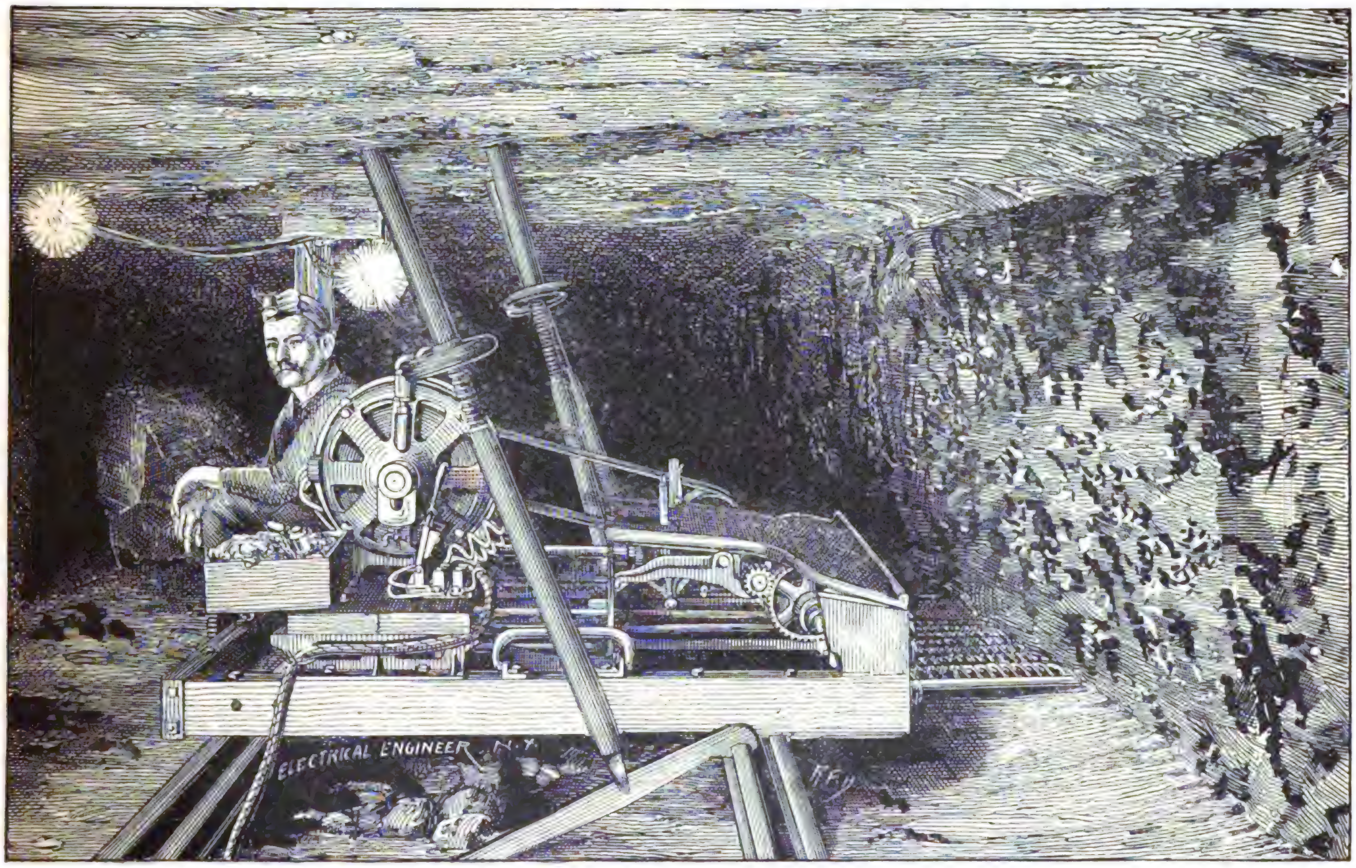

FIG. 2.—TESLA MOTOR DRIVING HERCULES COAL MINING MACHINE.

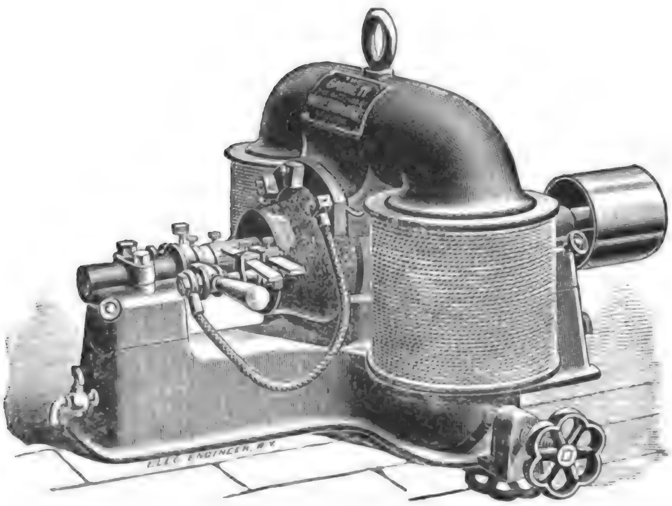
a similar equipment in Mr. Frank Armstrong's Summer Hill mines at Woodville, Pa. This company has done considerable of this work, and has on hand several orders for electrical mill and mine outfits. It has also designed a special electric mine locomotive and sparkless signal system, which is very essential in gaseous mines.

THE BARRIETT MOTORS.

For some time past Mr. S. L. Barriett, electrician of the New York Electrical Manufacturing Co., recently organized by Mr. A. Noll, has been engaged on the designing of various sizes of electric motors, the manufacture of which has now been actively undertaken and which embody a a number of novel features worthy of description.

Beginning with the large machines, Mr. Barriett has chosen the design shown in the accompanying engraving, consisting of a consequent pole field having wrought iron cores with cast iron yoke piece and base. The core of the armature is built up of annealed charcoal Norway iron discs, which are first rumbled, in order to remove the scale and to get rid of the sharp corners left by the stamping process. One sheet of insulating paper is placed between adjoining plates and two sheets at every fifth plate.

In order to make the magnetic circuit as perfect as possible, the joints between the field cores and the yoke



The Barriett Motor.

pieces and base are scraped so as to bring the metallic surfaces in absolute contact over the entire area. This, of course, reduces the resistance of the magnetic circuit considerably, as is shown by the high efficiency obtained in the machine.

The armature discs are not mounted directly upon the shaft, but upon a hardwood sleeve which is run over the shaft, and the armature discs clamped by end plates having teeth for the guidance of the armature wires and in order to retain them in position. The spindle is left rough until the discs are all mounted upon it and screwed up, after which it is turned down true to a B. & S. plug gauge.

Mr. Barriett is a thorough believer in securing perfect running balance for all revolving parts, and hence has devoted special care to this consideration. Thus, in the first place, the core, when mounted upon the spindle, is balanced without the winding upon it, but with the pulley mounted at the end of the spindle. The latter is also finished all over in order to obtain perfect balance. The armature is then wound and balanced again, the final balance being obtained by the solder on the holding-on bands.

Thorough lubrication has also been provided for in a very ingenious way. Situated below each bearing is a large reservoir, which is filled with oil. Supported in loose bearings in this reservoir are two circular iron discs which dip into the oil, and are attracted to the spindle by magnetic action. As the spindle revolves the discs constantly turn with it, bringing a continual fresh supply of oil to the bearings. A single filling of the reservoir suffices to lubricate the bearings for weeks without any attention whatever.

The machines of this type manufactured by the company range in size from $\frac{1}{8}$ h. p. up to 10 h. p., and in order to show the extent to which the material is utilized, we give below the details of the construction of the 1 h. p. Barriett motor designed to run at 220 volts:

Resistance of Armature, - -	.8 ohm
" " Field - -	430 ohms
Diameter of Armature, - -	5 inches.
" " Field cores - - -	$3\frac{1}{8}$ "
Length of Armature Core, - -	$5\frac{3}{8}$ "
" " Field " - -	5 "

The armature is wound with 60 sections of No. 21 B. & S. G. wire, with 28 turns to each section, and there are 30 segments in the commutator. The field is wound with No. 23 B. & S. G. wire, having a resistance of 430 ohms and with 7,990 turns on each leg. The motor runs at 1,850 revolutions per minute, and the pulley is $4\frac{1}{8}$ inches in diameter.

Mr. Barriett has also designed a very compact little fan motor, which has a magnetic circuit energized by a single field winding, and built up of laminated sheet iron baked in Japan varnish. The little motor is series wound, the armature having a resistance of 5 ohms and the field 400 ohms. Thus, when running at the full speed of 1,650 revolutions on a 110 volt circuit, the motor only takes one-sixteenth of an ampere. The work accomplished by the little motor is certainly astonishing, and the noise and vibration has been reduced to a minimum by shaping the fan blades in true helicoidal form, in exact imitation of a screw propeller.

These pigmies, as well as the machines of the larger type built by Mr. Barriett, are all made with interchangeable parts throughout, even the commutator on the smallest fan motor being made by standard machinery designed by Mr. Barriett for that purpose. The results obtained thereby are extremely satisfactory, resulting in a uniform product of the highest excellence.

THE OKONITE FACTORY AT PASSAIC, N. J.

Among the materials in use in electrical engineering work a leading place must unquestionably be given to the conductors employed. The best work in any direction, whether it be a dynamo, motor or any other piece of electrical apparatus, must to a large extent be affected if the conductor employed to connect one apparatus with another is defective. In the progress which has been effected in the construction of electrical apparatus generally within the last few years, that pertaining to the manufacture of electric wire and conductors of all kinds has not lagged behind. Indeed the result obtained within that period may be said to be little short of a revolution so far as the industry is concerned in this country. Not that good wire was not made before this period of great activity, but unfortunately it was not employed to the extent to which it was desirable to use it, with the result that frequent losses and other inconveniences were experienced, which, with good conductors, would never have occurred. Gradually, however, the consumers of wire began to realize the importance of employing wire having good insulation, with a result that the demand for this class of goods has reached proportions which are now scarcely realized, and the effect of which is to have built up an enormous industry, which is constantly on the increase.

Among the insulated conductors that have deservedly won a high reputation is that manufactured by the Okonite

Company, of this city, and we propose in the following to give a brief description of the methods employed by them. The works of this company are situated at Passaic, N. J., and as power is not an inconsiderable item in the cost of manufacture of any apparatus, the company have wisely situated their factory in close proximity to a large water power, which has thus far been unfailing in its supply for many years. The factory at this date is a three-story brick building, 380 x 60 feet, with a wing 70 x 120 feet, and engine and boiler room, 80 x 60 feet, adjoining. There are also carpenter, machine and blacksmith shops on the premises. The entire group of buildings and plant cover an area of about six acres; 400 hands or more are employed, turning out about 60 miles of insulated wire per day. Water power, as stated above, is used for driving the machinery. This is furnished by the Dundee Canal, on which the factory is situated, but in case this should be unavailable from any cause, a steam engine of 250 horse-power capacity proves an efficient substitute. In the engine-room is also a 50 horse-power Thomson-Houston dynamo, used in connection with the incandescent lights with which the factory is supplied.

FIG. 2.—TESTING ROOM IN THE OKONITE FACTORY.

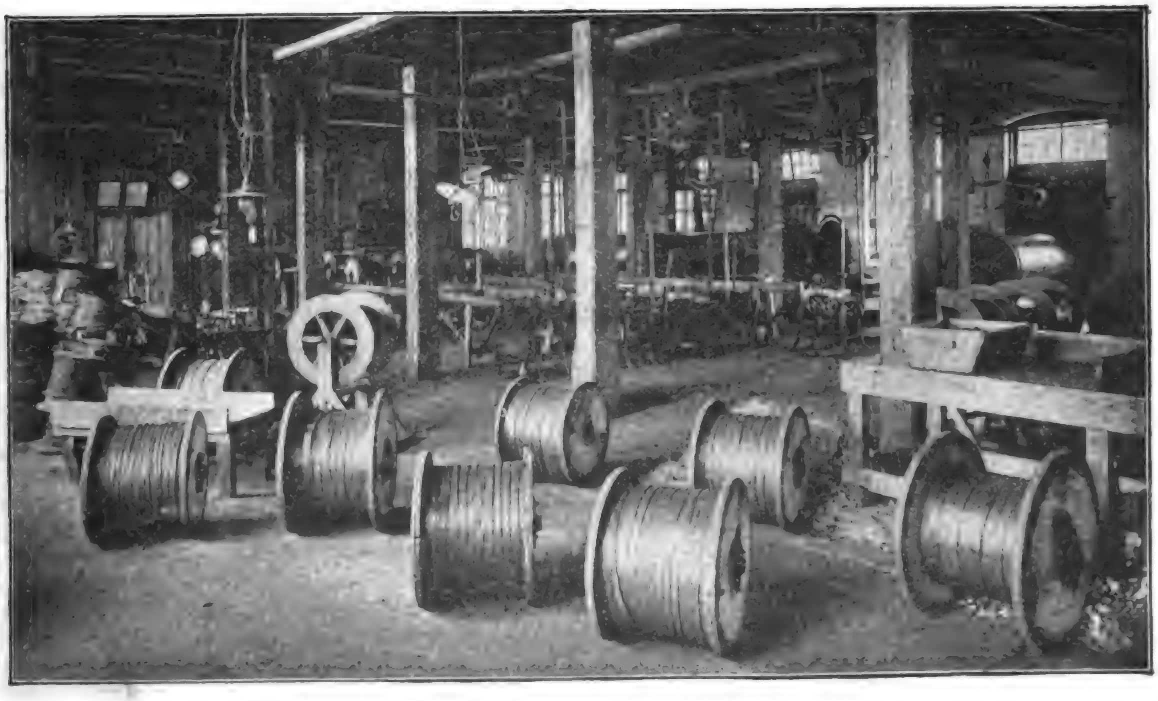


FIG. 1.—WIRE COVERING ROOM IN THE OKONITE FACTORY.

Proceeding now to the manner in which the wire is prepared, the first step necessary is to thoroughly clean the

surface of the copper and to tin it; for this purpose the wire is passed through a pickling bath and then through another of tin, which gives it a bright, smooth surface. The tinning, as is well known, is done to prevent the corrosion of the copper, which would reduce its effective cross-section when exposed to the air and moisture. When thus prepared it is ready for the application of the insulating material.

In applying this to the conductors the Okonite Co. pursue a unique process, which they claim insures perfection of insulation. Contrary to the usual method of what is known as "squirting," that is, passing the conductors through a templet and forcing the insulating material about it, the company employ the following method: The okonite material, which consists of a mixture of pure rubber with other ingredients, is rolled out into thin sheets exactly the thickness of the insulation required. This is then placed on wide strips of tinfoil and then cut into strips of a width sufficient to cover the wire of a given size. It is rolled on large reels in the form of a tape and passes to the next process, which consists in applying this tape to the wire. The accompanying engraving, Fig. 1, shows a scene in the room in which the tape is so applied to the conductor. The wire, guided by means of a templet, is surrounded by the

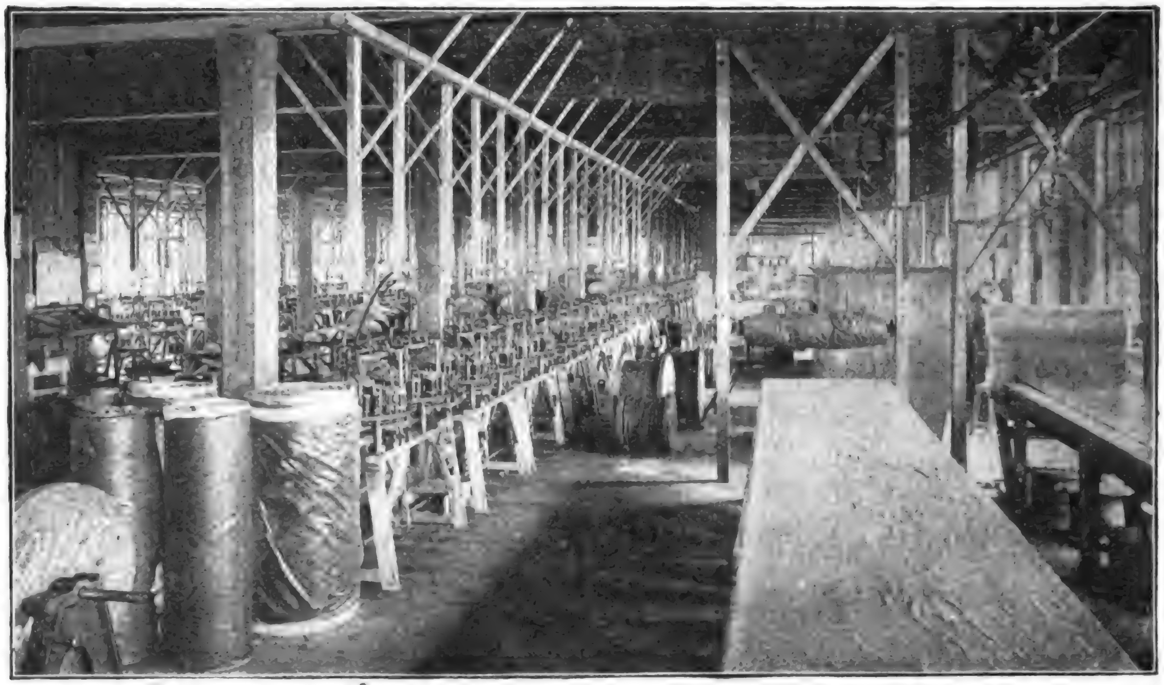

FIG 3.—BRAIDING ROOM IN THE OKONITE FACTORY.

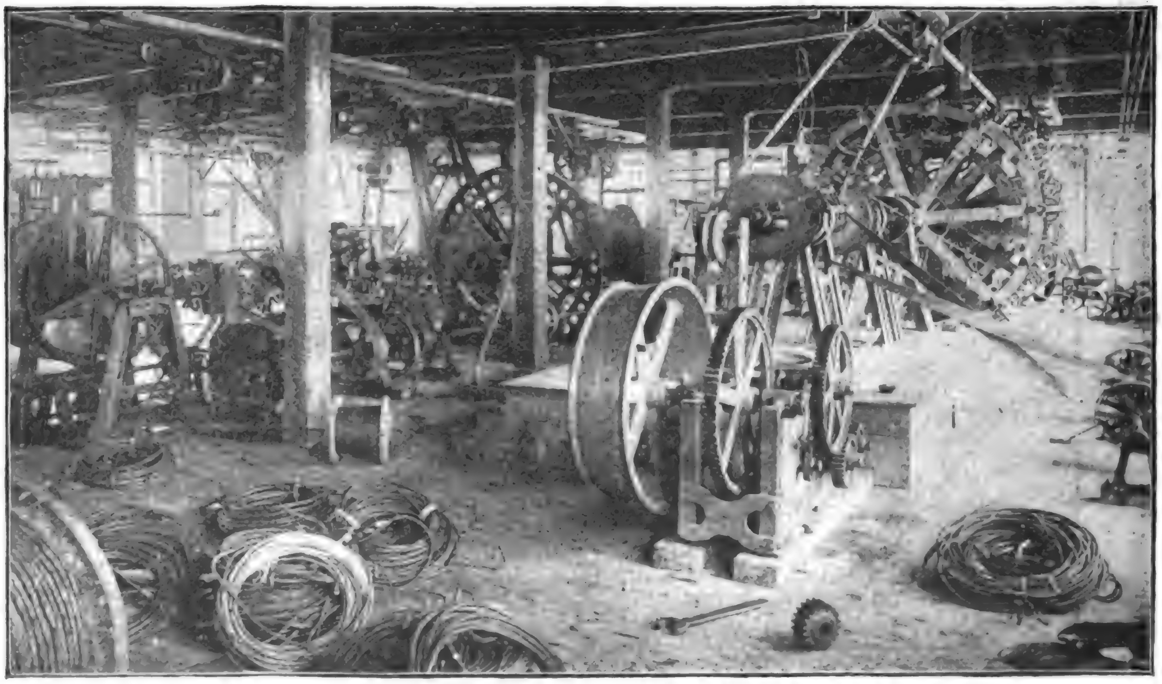

FIG. 4.—CABLING AND ARMORING ROOM IN THE OKONITE FACTORY.

tape, which is molded around it, leaving the burr on the edge which is so characteristic of okonite conductors. In this condition the foil-covered and insulated conductor is rolled up on large reels and placed in vulcanizers, where it is subjected to a temperature of over 300° F. These reels are kept constantly revolving, so that the wire may not settle down and displace the insulation, as would be the case if the wire were allowed to remain stationary in the vulcanizer. After remaining in the latter for the required time, the foil-covered wire is taken out and the foil stripped off, leaving the insulation exposed. The stripping process is accomplished at very great speed. In order to insure integrity in the insulation of the wire, it is, of course, necessary to test every piece before it is allowed to go out of the factory, and indeed the system of the company is such that a continual record is kept of every length of wire from the first to the last operation, so that any trouble which may occur can be directly traced to its source, and each handling must be accounted for by those in whose charge it is. After the wire has been insulated, it is placed in the testing tanks connected with the testing room, which is illustrated in the engraving, Fig. 2. Here the testing is carried on by means of four Thomson galvanometers and any faults located are noted. The methods of finding faults employed in the factory are very interesting. Of course a series of galvanometer tests might show and give an approximate indication of the location of the fault, which may only be a very slight leak; but as this would require some time, the method is employed of developing the fault so that it can be located very quickly. For this purpose, as soon as a fault is detected in a coil or reel of wire, it is placed in a special tank filled with water, one end being connected with the terminal of a dynamo developing an electromotive force of 2000 volts, and the circuit being closed to the other terminal by means of a plate immersed in the tank. The instant that the circuit is closed a flash occurs at the defective spot in the wire, and the insulation is burned out at that point. With the fault thus thoroughly developed, the coil is placed in circuit with a "buzzer" arrangement as a detector. The man in charge, by manipulating the various convolutions of the coil, by submerging and drawing them out of the water, is able to pick out the faulty convolution in the fraction of a minute, and the weak spot is at once located by the burn-out, which is always quite marked.

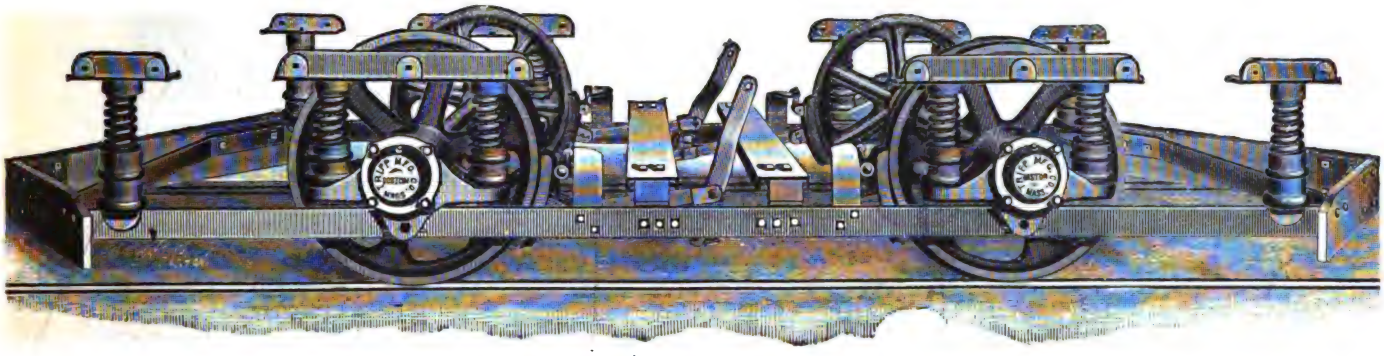
After the wire has been thoroughly tested, the next process it undergoes is that of braiding. This operation is performed in the room illustrated in the engraving, Fig. 3, a large number of machines being in operation in the factory for that purpose.

As is well known, the Okonite Company also manufacture cables for all electrical purposes and are equipped thoroughly with cabling and armoring machines. Several of these are employed, a few of them being shown in the engraving, Fig. 4. At the works there is also in constant operation a Thomson welding machine, by which all joints in the wires are made. The works are also lighted by the Thomson-Houston dynamo of 450 lamps capacity, which is the only illumination employed on the premises. The company do not employ coal as a fuel, but have arranged their own oil burning plant, which has given great satisfaction. The steam required is that employed for the use of the vulcanizers, since, as stated above, the water power is sufficient for the power required. Besides the insulated conductors of the highest grade manufactured by the company at the works, the Candee line wire is also made here and the Manson tape. The Candee line wire is first covered with insulating compound, then taped, then braided, and finally soaked in weather-proofing insulating material.

The works are under the supervision of Mr. F. Cazenove Jones, superintendent, with Mr. Christ. Klotzbach, assistant superintendent. As recently announced by us, the Okonite Company have lately made very influential English connections, and a branch factory for the manufacture of Okonite conductors is now being equipped in Manchester, England, which will be planned after the American works.

THE NEW STANDARD TRIPP ELECTRIC RAILWAY TRUCK.

The advent of the electric car and the suddenness with which it has sprung into favor have induced car builders to make large improvements in the form of truck, and among those who have devoted special attention to this branch are the Tripp Manufacturing Co., of Boston, whose latest and most improved form of truck we illustrate in the accompanying engraving.



The New Tripp Electric Railway Truck.

This truck is made for 14, 16 or 18 foot cars, with, or without, the extension springs shown in the engraving, which are designed to prevent oscillation of the car. For the largest car a bottom truss is used from end to end of the equalizing bar and bolted to it by four vertical supports. As will be seen, the equalizing bar is perfectly straight, and quite unlike the form now generally employed, which usually bends up over the journal boxes. The boxes in this case are simply bolted with steel pins through a lug on the box to the equalizing bar, which makes it extremely easy to lift the car from the wheels. All that has to be done is to jack up the car, take out the four bolts, and run out the wheels.

The Tripp trucks are noteworthy, not only on account of the Tripp anti-friction bearings with which they are fitted, saving a very large amount of power, but on account of their extreme simplicity, there being very few parts, and a minimum of bolts. They are being widely adopted all over the country by electric railroads, especially in the West, where the dust-proof bearings are proving very valuable. The saving in power effected is also an important feature in the West, owing to the high price of fuel. A large number of these trucks are now being placed in Van Couver, Seattle, and all along the Pacific coast, where a thoroughly well constructed and elastic truck is required, as the road-beds are not, as a rule, as good as in the East.

THE CROCKER-WHEELER PERFECTED MOTORS.

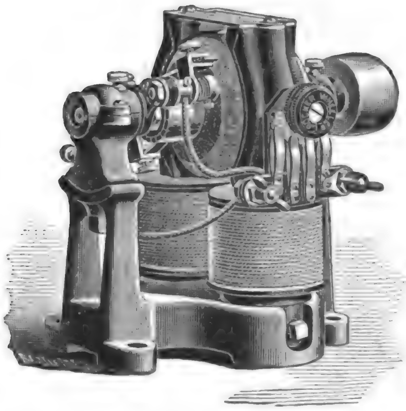
BY DR. S. S. WHEELER.

The type of machine now being constructed by the Crocker-Wheeler Motor Co. has been adopted after a long series of experiments, and is believed to be the best possible form for a perfect motor. It is the combination of a number of ideas with which we have long been impressed as being vitally necessary in the construction of perfect motors for practical work.

Believing that much of the expense usually incurred in placing motors upon the market might be saved if more attention were paid to what might be called the expensive construction of machinery in order that its operation should be cheap, and if machines were built heavier and stronger, they would obtain a much better footing with the public than could be secured by any other means.

Among the features which we have considered in need of special care are, the heating of motors, due to overcrowding with current, the want of attention to lubrication of the bearings, the imperfect insulation of the iron parts of the machine, the elimination of end thrust, the increase of contact surface of the field yoke, the removal of "armature support" from between it and the commutator, and the doing away with the probability of accidental grounds, and many other features.

We believe we have produced a series of motors which



The Crocker-Wheeler Perfected Motor.

are not only improved in all these respects, but which, being so improved, are practically perfect. The smallest of this series (1/6 h. p.) of which a view is presented in the accompanying engraving, is perhaps the most interesting on account of its extremely small size, and the fact that it embodies all of the new features alluded to. This motor gives its full power at 1,800 revolutions, with a weight of 25 lbs., and at an efficiency of 72 per cent. The magnetic circuit is of equal carrying capacity all around, the forged cores being set into a cast iron base to a depth sufficient to give a cross section in the cast iron enough greater than that of the wrought iron to make up for its inferior magnetic capacity.

The pillow blocks, which are of the self-centered style made to fasten with one bolt, carry bearings provided with universal ball joints for easy alignment, and self-oiling ring attachments. These rings, traveling upon the shaft, carry oil up continuously from the oil wells in the lower part of the pillow block. The use of self-oiling bearings has never before been attempted in small motors, but there can be little doubt that, in this particular, our advocacy of perfect construction for even the smallest motor is most important. The smaller a motor, the more likely is it to be put up anywhere—on a bracket—and neglected; therefore the importance of self-oiling devices is obvious. Fresh oil is supplied in these reservoirs every two weeks, instead of daily, as is usually required, by drawing off the old oil. This is accomplished by first removing the thumb screw from the opening at the base of the pillow block, and then putting in fresh oil at the upper opening.

The armature is mounted on a face plate on one side only, thereby freeing the commutator and its connections from any possibility of accidental grounding against an inside supporting spider. The armature and its connections are entirely covered, as in larger sizes, to keep out metallic dust, etc. The brushes are supported on a rocker arm and are held in small brush holders, provided with adjustable steel tension springs, and the direction of rotation of the motor may be reversed by shifting the rocker arm and reversing the brush holders. The rocker arm may be rotated the entire 360 degrees, a sufficient space being left around the bearings to clear the nuts on the ends of the brush rods and the flexible cable connections, so that in no position of the brush fittings could any accidental contact occur. The armature core reaches close to the inside of the pole pieces, and, being of the same width as the latter, holds the armature centralized by its magnetic attraction and relieves the shaft of all end thrust; in fact while it is thus held without friction, it is held so powerfully that it is not disturbed by the thrust of a large fan attached to the shaft.

These machines are wound for any number of amperes or any number of volts; those wound for incandescent circuits being of three classes: "Plain series" for steady work, such as driving fans and pumps; "plain shunt," for variable work, which requires that the motor itself maintain steady speed automatically; and "series with double speed," used for running fans and other work at either slow or high speed. The controlling switch is attached to one of the pole pieces directly over the field coil, so that all of the connections are made directly from beneath. In the case of the "shunt" machines, a starting coil for the armature is wound upon the nearest leg of the field, and is so connected that when the armature current passes through it in starting, it tends to strengthen the field.

The outside dimensions of the machine are $9\frac{1}{2} \times 8\frac{1}{2} \times 6\frac{1}{2}$ inches; diameter of shaft, 3/8 inch; revolution of constant speed machine 1,800, or as slow as 1,000 when required.

"AJAX" CENTRAL STATION AND POWER SWITCHES

BY C. S. VAN NUIS.

Since the general adoption of electricity for transmitting power to great distances, for the operation of street railways, mills, mines and other industries, electricians have given their energies to the task of designing reliable apparatus for the generation, control and manipulation of the necessarily heavy currents at greatly increased potentials.

Modified forms of the already familiar generators and motors have shown themselves efficient in the new field; improved line wire and insulators have had the desired effect of increasing the insulation of long circuits; current indicating apparatus has had a share of thought and attention, and a corresponding advance has been made in that part of the station outfit.

In the line of progression, and in response to the demand for a better station switch, suitable in design for any current capacity at any potential, and which should be reliable under all conditions, the conception of the principle of the "Ajax" switch was formed.

Probably the first requisite in any switch should be ample current-carrying capacity. This can be obtained by using sufficient metal of good conductivity, and securing good, rigid contact surfaces.

Next in importance to carrying capacity should be the breaking capacity. If it is important to have a snap movement in an incandescent lamp socket, where one-half ampere of current is used, it surely ought to be essential in a larger switch. How often have we seen well proportioned switches blackened and blistered, sufficiently to impair their usefulness, because, in an emergency, or a

moment of careless forgetfulness, an attendant had opened the circuit at that point while a partial or full load of current was passing Many-slow motion station-switches are placed where it is predetermined that no current shall be flowing when the circuit is opened, yet the emergency comes, sooner or later, and the result is as described.

The "Ajax" switches are made of metal of high conductivity, properly proportioned and finished, so as to secure a maximum carrying capacity for a minimum amount of metal, and, being mounted on slate bases, they are practically indestructible from any reasonable overload. The new carrier and spring causes an instantaneous break across two or more long lines of contact, simultaneously, which movement is entirely uncontrolled by the hand of the operator, and eliminates burning of the points of contact, when called upon to open, or break, its maximum load or a short circuit. Hence it would appear to be thoroughly reliable in the hands of the most ignorant, and wholly indestructible in any use for which it is intended.

The accompanying engraving, Fig. 1, illustrates a station dynamo switch of 200 amperes capacity designed for single trolley railway work. As will be seen, the snap movement is obtained by the employment of a hollow slotted carrier, pivoted on the same bolt on which is hung the cast

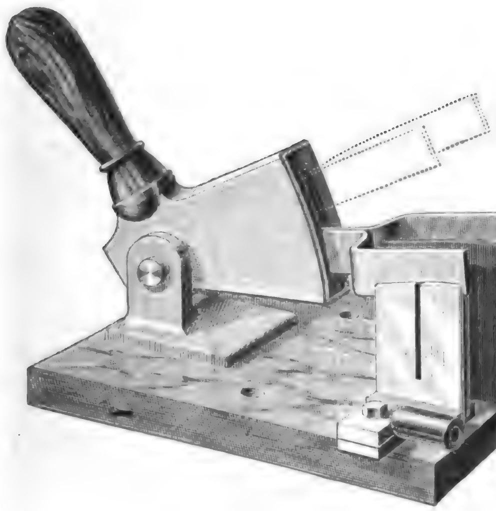


Fig. 1.—The "Ajax" Double Pole Switch.

tongue, which supports the current-carrying blade. Within this hollow carrier is a flat leaf spring, with one extremity extending into the handle and fastened there, while the other bears directly on the lower end of an extension of the cast tongue. When the handle is pressed backward the carrier moves in a vertical plane, while the contact clips hold the blade and tongue stationary until the stop at the lower end of the slot in the carrier bears on the tongue; then all raise together.

While the tongue remains stationary, the moving carrier exerts a pressure on the spring, which is sufficient to overcome the friction of the clips on the blade before the latter quite reaches the top, so that an exceedingly rapid movement is acquired at the lines of breaking contact, independent of the movement of the handle by the operator. The current-carrying blade is so bent and placed in all of the high potential switches of the "Ajax" type, as to admit of an insulating screen being placed between the clips, which engage the extremities of the blade, thus obviating the possibility of an arc between the contacts when the circuit is opened. A flat spring, composed of two or more leaves, was selected for these switches as the type combining the greatest elasticity with longest life.

For currents not exceeding 300 amperes at 600 volts, a switch as above described will open a short circuit without the slightest injury to contacts; and by the addition of a pair of simple spring brass brushes, so arranged as to shunt the main circuit on two carbon plates and to break the shunt circuit last, an "Ajax" switch can be made to successfully break an almost unlimited amount of current at a very high potential.

As an example, we may mention an "Ajax" switch which had repeatedly broken a circuit carrying 850

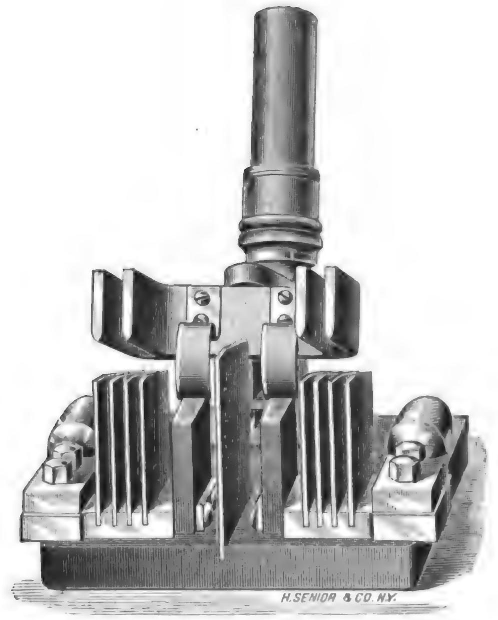

Fig. 2.—The "Ajax" Double Pole Switch.

amperes, close inspection of which failed to show that the switch had ever been used, so complete was the protection against burning or arcing.

The accompanying engraving, Fig. 2, shows the double blade for very heavy capacity switches, as well as the carbon plates of the shunt circuit, with the light brass springs still in contact after the main circuit is broken.

The illustration, Fig. 3, gives a good idea of the form of the "Ajax" feeder switch cut-out. This form of switch occupies a very limited space on the switch board, a valu-

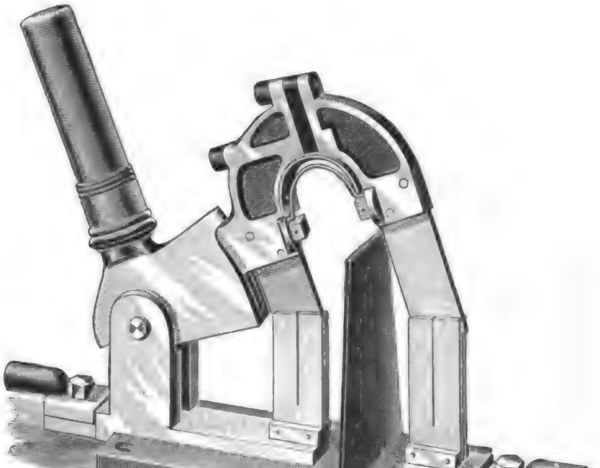

Fig. 3.—The "Ajax" Double Pole Switch.

able item where a short "bus rod" is required to supply current to many feeders, and, as shown, makes a very desirable form of feeder cut-out. A suitable insulation is inserted in the curved tongue, so as to electrically separate its ends; the under surface of the arch is lined with fibre, which projects well beyond the sides of the castings, so as to prevent the formation of an arc when the fuse melts;

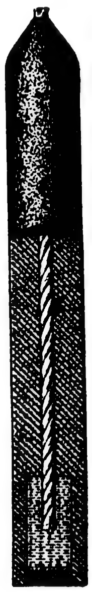
and large cap screws, with washers, secure the ends of the fuse wire which electrically connects the copper blades.

By this construction, it will be seen that, besides the small space occupied, one insulating screen answers for both cut-out and switch and that a fuse wire can be replaced while the switch is open, and consequently out of circuit, without the usual multiplicity of connections to accomplish the same result.

The "Ajax" switches are already well-known among street railway men using electricity as a motive power, and they are being sought by users of stationary motors and large incandescent lighting plants, who appreciate their qualities of indestructibility and simplicity of action.

SAUNDERSON'S IMPROVED ARC LIGHT CARBON.

For many years there have been efforts made for the improvement of carbons for electric arc lamps with some measure of success, also for introducing various materials into the arc, but in no case has any important advantage been gained. In many cases certain substances have been ground up and incorporated with the carbon, with the result that ashes or clinkers have been formed to such an extent as to render the light of less rather than greater intensity. The most successful carbons have been those



The Saunderson Arc Light Carbon.

made up with finely powdered soft carbon dust. A very remarkable discovery, says the London *Electrical Engineer*, has been made, which will certainly give an enormous impetus to electric lighting. The inventor, Mr. Llewellyn Saunderson, of Kingstown, County Dublin, whilst experimenting with the arc lamp in his endeavors to improve its powers to pierce fog, so as to minimize loss of life at sea, determined upon introducing into the arc minute quantities of intensely heated hydro-carbon vapor, so as to enrich the light with the well-known fog-piercing rays, viz., yellow and red. Having succeeded by this means in producing a beautiful sunshine yellow, he discovered that at the same time the intensity of the light was enormously increased. A plant was put down, consisting of gas-engine, dynamo, and electric arc lamps, and the innovation was followed up by introducing various gases in to the arc in a number of curious ways, only a few of which can now be described. The first consisted of a jet through which the vapor was projected into the arc, then two jets, and so with a number of other contrivances. The hydro-carbon was vaporized in the tube leading to the jet, and retarded in its passage by asbestos, etc., to give the carbon time to bring the vapor up to an intense heat, and a wick was employed to prevent the vapor from going back, as well as to supply fresh fluid by capillary action.

In a series of tests recently made by Dr. John Hopkinson, with the Saunderson carbon, two arc lamps were provided, identical in all respects, with the exception that one of them was provided with the new carbon which is illustrated in the accompanying engraving. The E.M.F. and current supplied to each arc were measured by voltmeters and ampere-meters, which were afterwards compared with each other, and were found to give the same indications for the same currents. The lights given by the two arcs were compared by a photometer, generally of the ordinary construction.

The final results arrived at by Dr. Hopkinson were as follows: Mean potential of ordinary lamp, 39.8 volts; of new lamp, 41.4 volts; mean current of ordinary lamp, 12.4 amperes; mean current of new lamps, 11.1 amperes; mean energy in ordinary lamp, 493.5 watts; mean energy of new lamp, 459.5 watts; mean ratio of the light given by the new lamp to the light given by the old lamp, 1.88. Thus, in these experiments, whilst consuming somewhat less energy, the new lamp gave nearly double as much light as the old lamp. Dr. Hopkinson concludes, therefore, that in an arc of this size a substantial advantage is gained from the use of the invention.

Among the other advantages claimed for this discovery we may mention increased steadiness, and, instead of the bluish tint always present in the ordinary arc, a fine rich, yellowish-white color, very agreeable to the eye, is produced, being almost exactly the same as sunlight, and having, it is said, an enormously increased power of penetrating fog, so important for lighthouse purposes, and for use in the military and naval electric light projectors.

The item of expense in applying the new system is said to be so small that it may be neglected altogether, and very little or no alteration of the present arc lamps is required. The simplicity and cheapness of manufacture is, in fact, so great that it is probable not more than 20 per cent. or 30 per cent. in total cost need be added to the present cost of the carbons against the diminution of the general cost.

It may well be asked how these results are attained. Up to this moment there is, perhaps, no sufficient explanation, but it is highly probable that the exceedingly fine particles introduced into the arc, and impinging against the upper carbon by the ascent of the hydro-carbon vapor, are acted upon with great advantage by the electrical energy, whereas the harder particles of the carbons have to be taken from their state of cohesion, greatly reduced in size, and even then only a small percentage are found suitable for the higher incandescence (from which most of the light is derived), the grosser particles falling in dust, found after the lamp has gone out; while portions more refractory are discharged at all angles, and sometimes with considerable force.

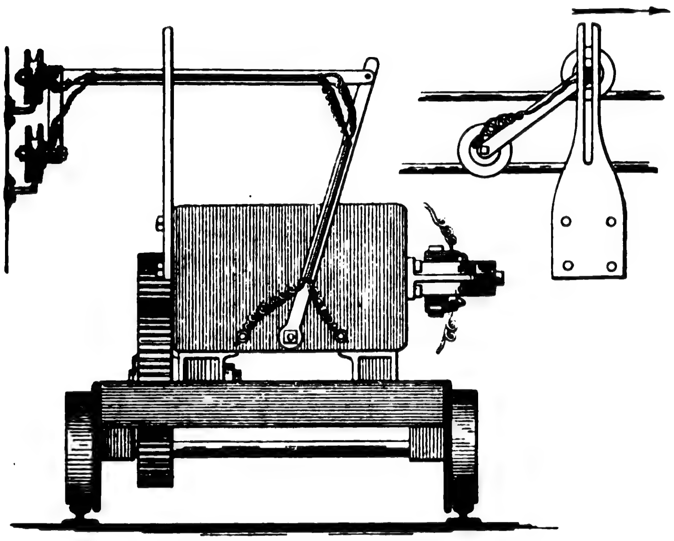
The quantity of vapor required is astonishingly small, that which can be produced from a drop of oil lasting, with ordinary carbons, nearly a minute. It is, however, not necessary to employ oil, but almost any substance or semi-liquid which on being heated gives off the vapor will answer well. For example, vaseline, enclosed in a small capsule of the same size as the rod of carbon, and not more than about ½ inch long, will hold sufficient for the burning of the carbon down to the usual length at which it is generally taken out and thrown away. It is probable that the minute quantity of vapor required is acted upon freely, and that in its turn the incandescent gas or particles of vapor assist largely in effecting the separation of the particles of the carbon electrodes, for the consumption of carbon is increased by about ¼th part.

This invention is now being-tried in a large installation in England. The results have been found to be practically the same as those certified by Dr. Hopkinson.

BAIN'S ELECTRIC COAL MINING MACHINERY.

AMONG those who have devoted considerable attention to applying the electric current in various ways to the operations carried on in coal mines is Mr. Foree Bain, of Chicago; indeed, he claims to be the pioneer of this work in this country, it being now about one year and a half ago that he installed a complete electric plant in the coal mines of the Shawnee and Iron Point Iron and Coal Company, at Shawnee, Ohio. This plant consists of a well-known coal cutting machine, which had been previously operated by compressed air, but is now driven by a Bain mining motor an electric locomotive capable of hauling a train with 25 tons of coal up a 5 per cent. grade, and a system of incandescent lamps from the same circuit, which are used to illuminate the rooms and entries of the mine.

The electric locomotive employed in the mine is capable



BAIN'S ELECTRIC MINING MACHINERY.

of hauling 1,000 tons per day; one boy who is paid $2 per day to run it and another who gets $1.25 per day to couple cars and attend to switches, is all it costs for wages, and they take the place of 15 drivers and 15 mules, and, according to Mr. Hull, the superintendent, "it is an unquestioned success."

Mr. Bain has recently worked out and patented a complete system of mining coal by electrically operated machinery, which consists of an undercutting machine and an overhead drill for drilling a hole in which to place the blast. This hole is drilled at the same time the undercut is made, and is operated simultaneously by the same motor.

The undercutting machine is made in two principal parts, viz., the outside frame to which the traction wheels are removably attached, and the inner frame which telescopes within the outer frame; the inner frame carries the motor and the drills. There are thirteen drill rods placed parallel and in front of the motor, and every alternate drill rod carries a special steel conveyer, stamped from sheet steel and firmly secured to the rod. The object of the conveyer is to remove the cuttings from the drills while the slot is being cut into the coal. The drills or cutting bits are removably attached to these drill rods at their extreme forward ends in such a manner that they overlap each other in their rotation to cut through intersecting planes. The drills are grooved together near their rear ends to rotate alternately in opposite directions; by this arrangement it will be evident that a continuous slot, penetrating in most cases six feet, can be cut with rotary cutters, without interference of the cutters with each other. Their relative direction of rotation is such that should any one cutter for any reason tend to lag in its work, it would be assisted by those on either side of it.

The motor, which is mounted on the inner frame, and which rotates the cutting bits, also supplies the power which gives the system a reciprocating motion to feed into the coal; a clutch immediately in front of the motor connects it with the driving and cutting mechanism, and another, located under, and at the rear of, the motor, is thrown in one direction to withdraw the system after the slot has been cut. The retrograde movement is arranged for a speed four times faster than the speed at which the bits are fed into the coal. After the cut has been made the machine is shifted and another cut parallel with the first is made in the same manner, and so on, until the room has been finished. When it is desired to remove the machine to another location or room, it may be slightly raised and traction wheels put into the studs; the cutting machine may then be disconnected by use of the front clutch lever, and the machine then becomes self propelling and can move itself around on the floor of the mine or on the tracks in the entries. For long distances it is supplied with the trolley device, illustrated in the accompanying engraving, and it may also be used as an electric locomotive for drawing a small number of cars.

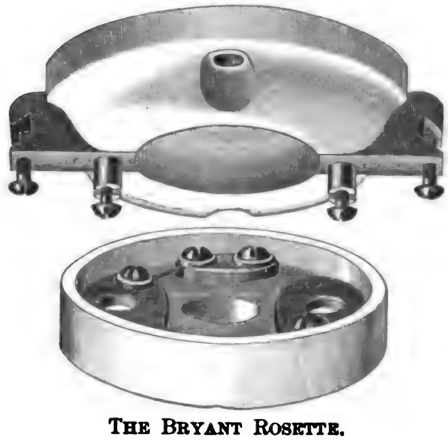
In good coal the machine will cut a slot three feet wide, four inches high, and six feet under within three minutes. It is operated by a specially constructed motor of only 6 h. p., which, like all of Mr. Bain's electric mining machinery, is operated at 225 volts.

THE BRYANT ROSETTE FOR FUSIBLE CUT-OUTS.

PRESENT practice in electric lighting requires that as far as possible each individual lamp shall be protected by a safety fuse, and this is specially required in pendant lamps suspended from rosettes attached to ceilings. These rosettes usually contain the fusible cut-outs, and when a burn-out occurs, the ordinary detachable cap is removed and a new fuse is inserted in the cap.

The attendant is thus enabled to avoid the inconvenience, as well as the danger, of accidentally completing the circuit while adjusting the fusible connections. In practice he removes the cap, places the fusible connections therein, then replaces the cap, and secures it in place. It is of course important that this connection should be made in the quickest and simplest manner possible, so as to avoid the formation of an arc while adjusting the cap in place.

In the rosette or ceiling block recently brought out by



THE BRYANT ROSETTE.

the Bryant Electric Co., of Bridgeport, Conn., a special arrangement has been adopted by means of which the attendant places the cap in position, so as to complete the circuit by a single movement, thus avoiding the formation of an arc. At the same time the construction is such that the positive and negative wires are connected at the same instant, and when the connection is once made it does not have to be broken in attaching the cap in place.

The manner in which this is accomplished is shown in the accompanying engraving, which illustrates the rosette, the cap being removed from the base. Both are made of porcelain. As will be seen, the base carries a pair of screw lugs, which are connected to the circuit wires. Cast on to

each lug is a short pillar carrying a screw, which is placed somewhat eccentrically in the pillar, and the object of which will be explained presently.

The cap carries a pair of brass plates to which the flexible cord is attached, and these plates are connected to a second pair of plates by means of the fuse wires. The latter pair, it will be noticed, are perforated and fit directly over the pillars on the connecting lugs in the base.

When the fuses have been inserted the cap is brought down on the base, the pillars passing through the perforated brass plates in the cap. By then merely screwing down on the screws in the pillars, the under sides of the eccentrically placed screw heads bear upon the brass plates, thus securing the cap firmly in place, and making electrical connection with the circuit wires at the same time. The construction is very simple and the block presents a neat appearance.

THE "CONVENTION" DOUBLE POLE INCANDESCENT SWITCH.

SIMPLICITY of construction, efficiency in operation, and cheapness are the three main points which are looked for in any good article. These three points are aimed at in the new "Convention" incandescent double pole switch, which we illustrate below, and which is manufactured by the Illinois Electrical Material Company, Chicago. The sectional view shows the contact bar resting on the insulated ratchets. To close the circuit it is only necessary to turn the handle to the right, and the bar will climb the

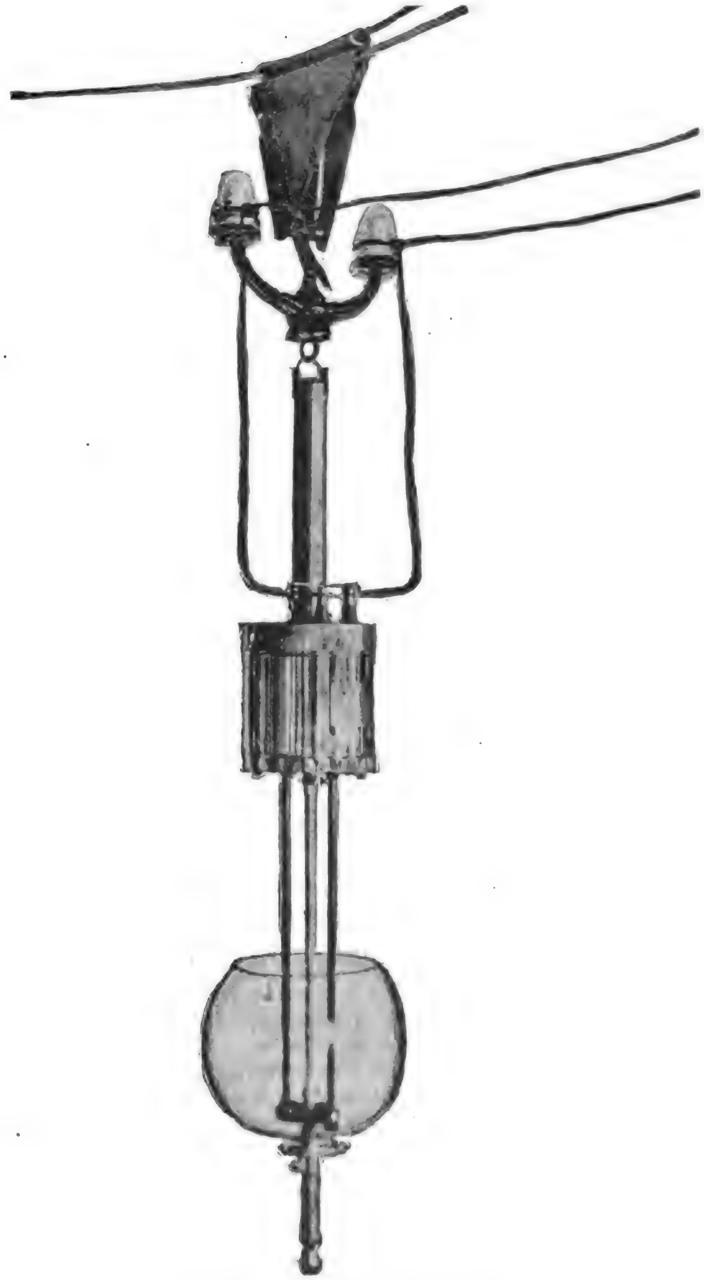
THE "CONVENTION" DOUBLE-POLE SWITCH.

grade and take a horizontal position on the brushes fixed on both sides, while a second turn gives an instantaneous brake, the bar being thrown off by the force of the spring about three-sixteenths of an inch. The ratchets are made of insulating material, as is also the block supporting the contact bars, the small slot cut sideways in the centre block aiding to throw the contact bar of the ratchet the necessary distance. To convert into a single pole switch, it is only necessary to remove the outer contact brush.

THE "FOREST" LAMP HANGER.

WHERE arc lamps are required to light outdoor or large interior space it is necessary to provide means for lowering them for cleaning and trimming, and in the past frequent trouble has arisen, and in some instances loss has been incurred, by the breaking or malicious cutting of the rope by which the lamp is suspended. To avoid this the Forest City Electric Works, of Cleveland, O., has recently brought out a novel lamp hanger which is illustrated in the accompanying engraving. As will be seen, the lamp is entirely supported by a hook on the line-wire supporting frame, which engages with a steel pin in the hood, thus taking all strain off the raising and lowering cord. This cord is not in use except when raising or lowering, and will, therefore, last much longer than when used to support the lamp. Cutting or untying this cord maliciously cannot drop the lamp, as, to disengage it from the hood, the lamp must be raised about six inches by the cord.

When used to support a lamp over a street, the sheet steel hood is supported by a cross wire or cable and held in position by as mall wire or cord running to the pole. This allows of placing a lamp readily at any point over the street,



THE "FOREST" LAMP HANGER.

and if it is desired to trim the lamp at one side of the street, as in the case of wires interfering, the position cord can be released and the raising and lowering cord will draw the entire hanger to one side of the street and release the lamp, which will then come straight down; and when trimmed it can again be pulled into engagement with the hood. The entire hanger with the lamp is then drawn along the cross wire to its proper position over the street.

By the construction adopted the lamp is also entirely insulated from the hanger and no strain whatever is brought on the lamp connections.

A NEW WALL BRACKET.

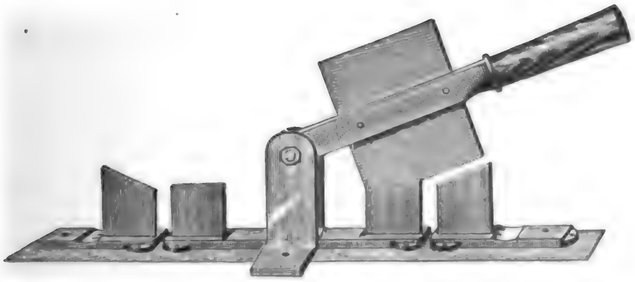
The same steady demand for higher insulation which has led to the production of good weather-proof wires, has also resulted in the bringing out of a finer quality of insulators and of better means of supporting them. The latest of these improved supporting devices is shown in the adjoining cut. It is called the "Springfield bracket," and is manufactured by the Great Western Electric Supply Co., of Chicago. Being made of malleable iron, with a ribbed arm and a hollow screw, it is very light, strong and tough. The split screw has a slight give to it and grips

A NEW WALL BRACKET.

the insulator tightly. The wall plate is also novel in design, being so shaped as to give a large spread with very little metal. The makers have, they report, in preparation other forms of malleable iron brackets embodying the same good features as the above.

ALTERNATING CURRENT SWITCH.

The accompanying illustration represents a new design in alternating current switches, just brought out by Messrs. J. Lang & Co., of Chicago, the manufacturers of the well-known "Andrews" switches. In the switch shown the contact is instantly made and broke across the entire face



ALTERNATING CURRENT SWITCH.

of the clips. The blade and tongue are made of the best hard rolled copper, and the brass used is of the highest conductivity. The switch is made in single or double pole styles.

NEW YORK SUBWAY LITIGATION.

The first skirmish in court in the $2,500,000 suit of the North American Underground and Electric Company against the Consolidated Telegraph and Electrical Subway Company has resulted in a defeat for the plaintiff company. The North American wants the Consolidated Company forced to use the Johnstone system of conduits and pay $2,500,000 damages for the failure to use the system. It also wanted an injunction pending the determination of the suit to restrain the Consolidated Company from laying or maintaining any other system of underground conduits than those of the Johnstone system. Judge Beach, of the New York Supreme Court, before whom the motion for the injunction was argued, handed down a decision on August 11 refusing to grant the injunction.

THE ASSOCIATION'S MEMORIAL TO CONGRESS ON THE ELECTRICAL CENSUS.

An important memorial has been presented to Congress in the name of the National Electric Light Association, favoring the authorization of a special census investigation, and report on electrical industry, and a special appropriation of $50,000 for that purpose. The memorial was presented by President Marsden J. Perry, through Senator Hale, and ordered to be printed. It is Misc. Doc. No. 197, Senate, 51st Congress, First Session.

This paper rehearses the familiar steps taken to secure the special census and appropriation by the Association and quotes the Census Act bearing on the subject. It points out that in the census of 1880 only three brief chapters are given to the telegraph and telephone, and it enumerates 41 leading subjects upon each one of which a special chapter should be written by experts. It then proceeds as follows:

"It is our duty to lay claim to all honors to which American inventors and artisans are clearly entitled for their genius of invention or skill of adaptation. This should be done by concise and circumstantial historical statements in the first official report ever published by any nation on the electrical industry. The proud pre-eminence of this country in these respects is most marked. There is not a nation in the world that is making use of the many practical applications of electricity without using the creations of American inventions or the products of American factories.

"How much reason there is for such claims and the broad field they cover will be readily understood when it is known that of the 205,479 patents issued by the United States Patent Office for the ten years ending December 31, 1889, 12,591 pertain to apparatus for some practical application of electricity. The profits of the Patent Office for those ten years have been $2,210,863.76, averaging nearly $10.76 per patent issued. Upon this basis, inventors working in the field of the electrical industry, have paid to the Government a profit of $135,473.62; therefore, in requesting that the Government shall authorize and provide for an exhaustive investigation of, and report upon, the electrical industry, they are only asking a fitting recognition from their beneficiary.

"It is believed that upwards of two hundred establishments are to-day engaged in the manufacture of electrical apparatus and supplies. The aggregate number of persons employed, the amount of material consumed, and the total capital engaged, are sufficient to rank this industry second to none other in importance. This is especially true when it is considered that about 80 per cent. of this industry has been brought into existence since 1880, and is engaged in the production of apparatus of a kind and for a purpose never before known in the history of the world. The single item of copper consumed annually by this industry is estimated at 50,000,000 pounds. The producers of copper are protected by a duty of 4 cents per pound. At this rate the tariff tax upon this industry for but one item amounts to $2,000,000 annually. In view of this it is clear that, from the stand-point of the manufacturers and their army of employés, the investigation sought and the appropriation therefor is not a request as for a favor to be done, but for the recognition of the Government's most liberal supporters.

"The magnitude and unquestioned importance of the services being rendered by electricity is made quickly apparent by the shortest possible mention of the principal features of its work. Since the tenth census the capacity of telegraph lines has been doubled and quadrupled by improvements in instruments. The wonderful feat of telegraphing to and from moving trains has been brought into practical use. The power of holding a conversation between persons in distant cities has been acquired. Electric nerves may now terminate in every office and residence, making communication with any centre of population in the world possible and easy. The outburst of every fire, the ambulance call for every accident, the secret information to the police of every crime, is intantly announced. All these features of improvements are fast rendering the conditions of urban life radically different from what they were a few years ago. New conditions are created, hitherto unknown to commercial and social life. To investigate and make an exhaustive, impartial, and truthful report regarding these improvements is a duty the Government owes to itself, for upon such information only can its action and that of the several States and the municipalities be intelligently based regarding questions of the first importance.

"In the department of mechanical illumination the gas industry, over fifty years old, can show but 1,043 central plants. There are to-day upwards of 1,500 electric central stations furnishing a light that was wholly unknown to commerce ten years ago.

"Street cars drawn by horses were first operated fifty-eight years ago. The system now includes about 5,902 miles of track, operating 18,000 cars, and carrying 3,600,000 passengers daily. The first electric road went into use only five years ago. There are now upwards of 1,753 miles of track, operating 3,000 cars, carrying 1,200,000 passengers daily.

"But three or four years ago the only method by which a working man could cause mechanical power to serve him in his efforts to maintain the independence of the self-employed was to

own a steam or water plant, the cost of which, together with its necessary attendant conditions, was prohibitory. He was thus condemned to spend his life as a wage-earner. To-day, at a monthly cost of about $10 per horse-power, clear of all collateral expense, he can obtain electric power delivered into his own home if he desires. For this small outlay, which every mechanic can easily make, there is placed at his command by the systems for the electrical transmission of power for stationary work physical power eight times that of his own strength, and he is able to use this vast and tireless power without effort for its production on his part. This not only largely increases his earning capacity, it opens the door to independent self-employment, the key to which is the ability to make mechanical power his servant.

"Going back less than five years, we find women thankful for the opportunity to tread out their lives at the machine, because thereby they found a means of honorable self-support. To-day, the tireless energy of electricity emancipates the woman from all physical effort to create power to operate her machine, at the same time increasing her earning capacity and enhancing enormously the ease and comfort with which her work may be done. This relief from the necessity of physical labor for men and women is accompanied by other conditions for the betterment of health and comfort that are moral and social factors of no less importance than the industrial and commercial. It allows the physical vitality formerly exhausted by the drudgery of treading out mechanical power to supply greater strength to the brain, nerves, and muscle, thus making a degree of intelligence—the soul of skill—easily attainable, that has heretofore been unknown. An interest such as this is worthy of the fullest recognition that can be given to it, not alone for its magnitude and the support the Government draws from it in a hundred ways, but for the sublime genius and enterprise that has induced, within one decade, an industrial and commercial development unknown to the centuries of the past."

The memorial then enumerates other lines of work of importance, and calls attention to the demand there is for data on electrical questions.

"The importance of these considerations can not be fully shown without calling attention to the urgent and wide-spread demand for the information indicated. The municipal council of every city, the legislature of every State, the National Congress itself, and governments of foreign countries, have all been persistently searching for it. This is conclusive evidence that it has never been collated and will be of the highest value when produced. Every city, every State, and the National Government is now spending money, in the aggregate an untold amount, in isolated efforts to obtain proper data upon which to base legislative action on questions of vital importance to the welfare of the people.

"Information obtained by the methods that have been followed must at best be incomplete and partial. The Census Office can in no way furnish a better demonstration of the incomparable value of its work than by obtaining and supplying the data as desired and indicated. The cost of doing this will not equal the cost of a single day's time of the legislative bodies throughout the country that require it for their use. Statements that electricity has caused the destruction of a certain amount of property by fire, has killed a certain number of people, or that the service rendered by it cost a certain amount of money, are absolutely valueless as guides to legislative action, unless they be made in comparison with the results of the use of other agents for the same purpose. The reasons given for making a special investigation of the electrical industry are reasons why the inquiry should be conducted with the greatest possible care, so that every point of comparison may be easily made, and all action based upon data officially published, may ultimate in sound economic and social results."

NEW ELECTRIC LIGHT AND POWER INSURANCE RULES.

WE publish below the new rules and regulations advised by the Boston Manufacturers' Mutual Fire Insurance Co. for the installation of electrical plants, and adopted not only by them, but by the Boston Fire Underwriters' Union and the Electrical Mutual Insurance Co. They were specially prepared by C. J. H. Woodbury, F. E. Cabot, C. M. Goddard and S. E. Barton. They are accompanied by a circular from President Edward Atkinson, in which he says:—"It may be stated that when electric lighting was first introduced, many years since, in mills or works insured by this company, mainly on the arc system, we had twenty-three cases of fire in sixty-one installations, but without any loss, within six months from the beginning. During that period the subject was thoroughly investigated and rules were prepared, by which all our members have been governed since that time; the rules now presented are a development rendered necessary by numerous inventions and improvements in the applications of electricity to illumination and to the transmission of power. There has not yet been a loss from any fire which could be attributed to electricity, generated for purposes of lighting or for motive power, in any mill or works insured by this company. The experience for ten years has sustained our position that a well installed electric lighting system is the safest method of illumination."

Dynamos and Switchboards.—1. Dynamos must be located in dry places, not exposed to flyings or combustible material, and must be insulated upon dry wood, filled to prevent absorption of moisture. They must be kept thoroughly clean and dry. They must be provided with a reliable, automatic regulating device, or a competent person must be in attendance near the machine whenever it is in operation. In wiring for motive power, the same precautions should be taken as with a current of the same volume and potential for lighting.

Each machine should be provided with a water-proof cover, which should be used whenever the machine is not in operation.

2. Switchboards, or other apparatus near the dynamos for controlling circuits and currents, should be so located that they will be accessible, and open on all sides, and entirely disconnected from all wood work or combustible material; also kept free from moisture. They should be incombustible, and rendered non-absorbent of water.

Motors.—3. They must be located in dry places, not exposed to flyings or combustible material, and must be insulated upon dry wood, filled to prevent absorption of moisture. They must be kept thoroughly clean and dry. They must be self-regulating, or a competent person must be in attendance near the machine whenever it is in operation. All resistance boxes or devices should be made of non-combustible material, or so located that they cannot communicate fire to any surrounding combustible material. In wiring for motive power, the same precautions should be taken as with a current of the same volume and potential for lighting. The motor (and resistance box) should be protected by a cut-out, and controlled by a switch.

4. Motor cars driven by electricity from a single wire with earth or floor return circuit will not be approved in any building insured by this Company. The use of such single trolley tracks may be permitted, after special inspection, in mill yards where there is no liability of other conductors coming in contact with the trolley wire, and where the conditions of the position of the generator is such that the ground circuit will not impose any fire hazard on the property.

5. Wires for electric lighting or stationary motors will not be permitted in the same circuit with trolley wires with ground return—the Stock Insurance Companies will permit such installations, subject to special inspection and agreement, on payment of a suitable charge for the permit covering this increased hazard —although the same dynamo can be used, if desired, for both purposes, provided that the connection from the dynamo to each of the two circuits shall be by a double-throw switch so that only one of the circuits shall be in service at the same time. In such cases the wires for lighting or stationary motors shall be in the usual manner, entirely on a metallic circuit without ground.

Testing.—6. All circuits should be tested at least twice a day with a suitable magneto, or other approved device, in order to discover any escapes to ground that may exist. One test should be made in the morning, and another in ample time before starting, to remove any defect, should it be found to exist. The rules for testing should be observed in any separate or isolated plant the same as in Central Stations.

ARC SYSTEM.

Outside Wires.—7. All outside overhead wires must be covered with some material of high insulating power, not easily abraded; they must be firmly secured to properly insulated and substantially built supports. All tie wires must have an insulation equal to that of the conducting wires.

8. All joints must be so made that a perfectly secure and unvarying connection, fully equal to the cross-section of the conducting wire, will be secured—and they should be soldered. All joints must be securely wrapped with an approved tape.

The following formula for soldering fluid is recommended:— Saturated solution of zinc, 5 parts; Alcohol, 4 parts; Glycerine, 1 part.

9. Care must be taken that conducting wires are not placed in such position that it would be easy for water, or any liquid, to form cross connection between them, and they should not approach each other nearer than one foot. The wires must never be allowed in contact with any substance other than air, and their proper insulating supports; except that service wires with special insulation may be permitted to touch foreign substances.

10. Conducting wires carried over or attached to buildings, *must* be at least seven feet above the highest point of flat roofs, and one foot above the ridge of pitched roofs. Lines constructed subsequent to the adoption of these regulations should not be run over and attached to buildings other than those in which the light or power is being, or is to be used, but should be on separate poles, or structures, where they can be easily reached for inspection.

11. When they are in proximity to other conducting wires, or any substance likely to divert any portion of the current, *dead, insulated* guard-irons must be placed so as to prevent any possibility of contact in case of accident to the wires or their supports. The same precautions must be taken where sharp angles occur in

the line wires, and also where any wires (telegraph, telephone, or others) could possibly, owing to their position, come in contact with the electric light wires.

12. Overhead wires from the main circuit or pole in the street to the terminal insulators attached to buildings, and at the point where they enter a building, must not be less than twelve inches apart. They must be rigidly and neatly run and supported by glass or porcelain insulators or rubber hooks.

13. Service blocks must be protected by at least two coats of water-proof paint over their entire surface; and, when used to support rubber hooks, must have at least one inch of wood between the inner end of the hook and the back of the block.

14. For entering buildings, wires with an extra heavy water-proof insulation must be used from the terminal insulators through the walls from the outside to the inside of the building. They must loop down, so that water may drip off, without entering the building, and the holes through which they enter should, where possible, slant upward.

15. Wires must enter and leave the building through an approved cut-out switch, which must be "double contact," and should effectually close the main circuit, and cut off the interior, when turned "off." It must be so constructed that there shall be no arc between the points when thrown "on" or "off." It should be automatic in its action in either direction, not stopping between points when once started. It should indicate upon inspection whether current be "on" or "off." It must be mounted on a non-conducting base, kept free from moisture, and easy of access to firemen and police.

Inside Wires.—16. Wires must not be concealed, and they must be rigidly kept apart at least one foot, unless an *approved, moisture-proof, non-conducting, non-inflammable tubing* is used. This tubing must be sufficiently strong to protect the wires from mechanical injury. It may be fastened to the wall by staples, provided the tubing is not broken or injured thereby. Wires in this class of tubing may be run as near as three inches to each other.

17. Conductors in buildings must be thoroughly well insulated with non-absorbent water-proof material, as incombustible as possible, which will adhere to the wire and not fray by friction, and will stand a temperature of 150 degrees without softening.

In places liable to dampness, wires must be thoroughly and carefully run on glass insulators, rubber hooks, or porcelain knobs of suitable size and shape, and the wires must be separated at least eighteen inches. They must also be provided with an approved water-proof insulation, or encased in an approved tubing.

When wires pass through walls, floors, partitions, timbers, etc., in-doors, glass tubing or so-called "floor insulators," or other moisture-proof, non-inflammable, insulating tubing must be used.

18. All lightning-arresters must be grounded outside of building, and preferably connected to a water-pipe.

Arc Lamps.—19. The frames and other exposed parts of arc lamps must be carefully insulated from the circuit.

Each lamp must be provided with a proper hand switch, and also with an automatic switch that will shunt the current around the carbons should they fail to feed properly.

Stops of some kind must be provided to prevent the carbons from falling out in case their clamps fail to hold them; and these stops must always be in place.

20. For inside use, the light must be surrounded by a globe resting in a tight stand, so that no particles of melted copper or heated carbon can escape. When any inflammable material is near or under the lamp, the globe must be protected by a wire netting. Unless a very high globe, which closes in, as far as possible, at the top, is used, it must be provided with some protector or spark arrester, reaching to a safe distance above the light. Broken or cracked globes must be replaced by perfect ones immediately. (By inflammable material is meant dry goods, clothing, millinery, and the like in stores; flyings or goods in fabric factories; shavings and sawdust in wood-working shops, or any other substance that can be readily ignited by droppings or flyings from the lamp.)

INCANDESCENT SYSTEM.

Incandescent Lamps on High-tension Circuits.—21. The rules for running wires for arc lamps apply also to incandescent lamps on circuits having a potential of over 350 volts. Incandescent lamps in single series on high-tension circuits must be provided with a suitable hand-switch, and also with an automatic device capable of shunting the circuit across the terminals of the lamp should the carbon filament break. When incandescent lamps are in multiple series, the hand switches must not control less than a single group of lamps, each of which may be provided with an automatic shunt, as above. Electro-magnetic devices will not be accepted as suitable for this purpose. Any method of distributing current to incandescent lamps on high-tension circuits, other than as above provided for, must receive approval before being put to use.

Outside Wires.—22. The rules 7 to 15 for outside arc wires also apply to outside incandescent wires, except that a cut-out switch in the circuit entering the building will not be required, but the wires from main circuit to main cut-out, inside of building, must be separated by a distance of not less than six inches, for currents having an electromotive force of 350 volts or less, and this distance must be increased for currents of high potential. They must also be rigidly and neatly run, and must be supported by glass or porcelain insulators, or by rubber hooks.

Underground Services.—23. Where underground service conductors enter a building, special care is necessary that they shall not come in contact with each other, or be placed where there is any risk of disturbance by moisture or mechanical injury.

There shall not be any free opening from underground wire conduits to buildings.

The service must not end in any place where it would be unsafe or undesirable to place a cut-out, but should be continued by means of specially insulated conductors (and a space of ten inches should be maintained between them) to a suitable location.

Inside Wiring.—24. For inside work, no wire smaller than No. 16 "B. & S.," or No. 18 "B. W. G.," will be approved. Before using any new form of insulation, the approval for its use under the proposed circumstances must be secured. The use of lead-covered wire, or wire the covering of which contains paraffine, is prohibited.

25. Mouldings with open grooves laid against the walls or ceilings will not be approved. A wood moulding with dividing strips between the grooves, at least half an inch in thickness, and having a backing of at least one-fourth inch thickness to intervene between the wire and the wall or ceiling of the building, the backing to be protected by at least two coats of water-proof paint and the moulding of such shape as to protect the wire from moisture, will be approved. Mouldings must not be used in wet places.

26. Wires laid in plaster, cement or other similar finish, or run over surfaces furred off for plastering, will not be approved, no matter what insulating covering is used. An approved moisture-proof, non-inflammable, insulating tubing or conduit may be used in such places. This tubing must be of sufficient size and so placed that the wires may be withdrawn and replaced at will. All joints and bends in this tubing must be made with suitable devices adapted especially for the purpose. Where this is done in such a way that the joints are moisture-proof, a double-braided cotton insulation, rendered non-inflammable, may be used.

A separate tube must be laid for each wire, except in the case of "taps" for not more than fifteen amperes, in which case conductors having insulation of cotton or other material which will readily carbonize, will be required. If a moisture-proof covering is desired, it must be placed outside the two conductors, and not between them. In other concealed places, such as unfinished lofts, between floor and ceiling, in partitions, etc., all wires must be covered with approved moisture-proof insulation, and fastened at distances not exceeding ten feet, so as to preserve at least two and one-half inches between the wires or any other electrical conductor. In lieu of such construction an approved moisture-proof, non-inflammable, insulating tubing or conduit with approved moisture-proof joints may be used, and the same rule as to insulation will be applied as in the case where the tubing is buried in plaster or similar material. Tubing passing through walls or ceilings must extend at least one inch beyond the finished surface, until the mortar or other similar material is entirely dry, when the projection may be reduced to one-half inch.

Tubes of such approved make may be laid side by side when imbedded in plaster or otherwise. At all outlets to and from cut-outs, switches, fixtures, etc., wires must be separated from gas-pipes or parts of the building by porcelain, glass or other non-inflammable insulating tubing, and should be left in such a way as not to be disturbed by plasterers. Wires of whatever insulation must not in any case be taped or otherwise fastened to gas-piping. If no gas-pipes are installed at the outlets, an approved substantial support must be provided for the fixtures.

Wires of the same polarity, but belonging to the different circuits, or leading to and from a double-pole switch, must not run in one groove, through the same tube, nor in the same slot in a cleat.

27. In dye houses, paper and pulp mills, and other buildings specially liable to moisture, all wires (except those used for pendants) must be separated at least six inches. The wire must be thoroughly and carefully put up, and must be supported by glass or porcelain insulators, or by rubber hooks. An approved, moisture-proof, non-inflammable, insulating tubing will be accepted in lieu of such construction.

28. In crossing any metal pipes, or any other conductor, wires must be separated from the same by a block of wood or other non-conductor of at least one-half inch, and so arranged that they cannot come in contact with each other by accident. Wires should go *over* water-pipes where possible. When wires pass through walls, floors, partitions, timbers, etc., in-doors, glass tubing, or so-called "floor insulators," or other moisture-proof, non-inflammable, insulating tubing must be used. Wires must never be left exposed to mechanical injury, or to disturbance of any kind. Wires of the same polarity, but belonging to different circuits, or leading to and from a double-pole switch, must not run in one groove, through the same tube, nor in the same slot in a cleat. Cleats should be made of well-seasoned hard wood (filled

to prevent the absorption of moisture), porcelain, or other approved material, and so made as to separate the wire at least one-fourth inch from the building. When secured by cleats not over four feet apart and tightly stretched, wires having a difference of potential of 120 volts or less, and carrying not over ten amperes, should be separated at least one and one-half inches; when they are confined in molding, a half-inch space is sufficient. Mains carrying currents of larger volume should be separated a greater distance.

The use of metal staples for securing wire will not be approved.

29. Where exposed to corrosive fumes, wires should be provided with an insulation that will not be injured thereby; and should be put up in the manner described in Rule 27.

30. All splices in wires must be soldered in accordance with Rule 8. A soldering bolt should be used for this purpose, if possible. Care must be taken not to render the wire brittle by overheating. The insulation of any joint must be equal to that of other parts of the same wire.

Safety Cut-Outs and Switches.—31. Every portion of each installation must be equipped with double-pole, safety cut-outs, that will interrupt the passage of a current in excess of the amount which any portion of the apparatus is adequate to transmit. A cut-out must be placed where the underground or overhead service joins the inside wires, and at every point where a change is made in the size of the wire (unless the cut-out in the larger wire is intended to protect the smaller). The plug or other device for enclosing or supporting the fusible strip or wire should be incombustible and moisture-proof, and so constructed that an arc cannot be maintained across its terminals by the fusing of the metal. No lead or composition strips carrying more than ten amperes before melting shall be used, unless provided with contact surfaces of some harder metal having perfect electrical connection with the fusible part of the strip. On any combination fixture, no group of lamps requiring a current of seven amperes or over shall be ultimately dependent on one cut-out. But there shall be a cut-out to each pendant and fixture.

32. Switchboards and cut-outs should be made of incombustible material, and arranged so that there will not be any leakage of electricity across them. They should be put in places not liable to contact with foreign substances, nor exposed to moisture.

33. All switches except those in lamp sockets should be double-pole.

They must have a firm and secure contact that will make and break readily, and that will not stick between "full on" and "off," nor get out of repair easily in other ways. The points of contact must not be allowed to scrape, or rub, the entire surface of an insulating material between the contact strips; an air space must intervene. The carrying capacity of the different parts must be sufficient to prevent heating.

Fixture Work.—34. In all cases where wires are concealed within or attached to fixtures, the latter must be insulated from the gas-pipe by some approved device.

When holes are drilled in fixtures, all burs or fins must be removed from the edge of the holes before the conductors are drawn through.

When wired outside, the conductors used must be so secured as not to be cut or abraded by the pressure of the fastenings or motion of the fixture.

All wire used for fixture work must have an insulation that is durable, and not easily abraded; and must not, in any case, be smaller than No. 19 "B. & S.," or No. 20 "B. W. G."

Each fixture must be tested for possible "contact" between wire and fixture, and for "short circuit" before current is turned on.

The tendency to condensation within the pipes or fixtures should be guarded against by sealing the upper end.

No combination fixture with less than one-fourth inch clear space between the inside pipe and the outside casing will be approved.

Pendants and Sockets.—35. Cord pendants must be composed of stranded wire, and protected by rubber bushings, or something equally good, where they enter the socket.

When exposed to weather, or used in wet rooms, care must be taken to keep moisture from the inside of sockets.

The weight of every socket and lamp suspended by a cord must be borne by a ceiling block, rosette, or cleat, and by a knot under the bushing in the socket, in order to take all strain from the joints and binding-screws.

Flexible cord must not be used except for pendants, wiring of fixtures, and portable lamps.

Secondary Generators or Converters.—36. Converters must not be placed inside of any building except central stations, and should be enclosed in a metallic or non-combustible case. They may be placed on the outer walls when in plain sight and easy of access, but must be thoroughly insulated from them. If placed on wooden walls, or the wood-work of stone or brick buildings, the insulation must be fire-proof. When an underground service is used, the converter may be put in any convenient place that is dry and does not open into the interior of the building; this location must have the approval of the inspector before the current is turned on.

37. If for any reason it becomes necessary that the primary wires leading to and from the converter should enter a building, they must be kept apart a distance of not less than twelve inches, and the same distance from all other conducting bodies.

38. Safety fuses must be placed at the junction of all feeders and mains, and at the junction of mains and branches when necessary; also in both the primary and secondary wires of the converter, in such manner as not to be affected by the heating of the coils. Secondary wires, after leaving the converter, will be subject to rules already given for inside wiring for incandescent lighting.

The secondary circuit may be provided with a film cut-out, which connects to the earth outside of the building; but permanently grounding the secondary circuit is unsafe and will not be sanctioned.

**Foreign Wires.*—39. No foreign wires of any kind shall be attached to buildings insured by this Company, for the purpose of carrying electric currents across the yard to any point.

40. All electric wires which may be required by the insured shall enter the premises at one point, preferably near the headquarters of the night watchman, where they can be kept under supervision; each of said wires shall be guarded by a protector against strong currents, operating by opening the circuit, and by a lightning-arrester.

41. Such protectors against strong currents shall be located in a dry, accessible place inside the building, and as near the point of entrance of wires as possible, and shall be without ground connection; such protectors shall be mounted on non-combustible and insulated supports, which shall be provided with a receptacle for the burning or melted parts of such apparatus.

42. The lightning-arresters on all wires must be placed between the protector against strong currents and the electrical portion of the apparatus within the building to which such wires are connected. No ground wires for such lightning-arrester shall be attached to gas-pipes within the premises of the insured.

43. All electric wires which may enter the premises of the insured must be insulated between the line wire on the insulator attached to the buildings outside and the protecting device within, with the best quality of water-proof insulation. Moreover, such wires must enter at a distance of not less than three inches from any other wire or any conducting material.

44. If any wires carrying high tension or strong currents are to be carried over or under other wires on the property of the insured, they shall be attached to poles so near to each other, with one wire so far above the other, that if a break should occur, the pendent wire between these poles may not be long enough to come in contact with the wire below, or, if not carried on poles, these wires shall be so placed or protected with guard-wires as to render a contact between different wires impossible.

45. If the high and low tension systems are in use in the same yard, even when developed within the works, the wires must be kept separate, and so wide apart that no contact or cross arc can be made.

Notice.—46. The Underwriters reserve the right at any time to add to, change, or modify these Rules, and to enforce such modifications, changes, etc., as shall be deemed necessary for safety; all reasonable efforts will be made to notify promptly all Electric Light Companies of any change.

THE DISCHARGE OF ELECTRICITY THROUGH GASES.

In a recent note appearing in *Nature*, Prof. J. J. Thomson writes as follows: "In the Bakerian lecture on 'The Discharge of Electricity through Gases,' in the last number of the Proceedings of the Royal Society, Prof. Schuster says: 'I do not see how the insulating power of air at the ordinary temperature is consistent with the presence of ions, however few in number, for ultimately a diffusion to the electrodes and a discharge would necessarily take place. This seems to me to be fatal to J. J. Thomson's views of the disruptive discharge.'

"This statement implies a misconception of the theory of the electric discharge advanced by me in the *Philosophical Magazine*, June, 1883, for there is nothing in the theory of the discharge there given which makes the presence of free ions in air at ordinary temperatures and pressures essential. I will quote two sentences from the paper to show what the theory is: 'In order to make the spark pass through an elementary gas, we have to decompose the molecules into atoms. Thus the stronger the connection between the atoms in the molecules, the greater the electric strength.' 'Chemical decomposition is not to be considered merely as an accidental attendant on the electrical discharge, but as an essential feature of the discharge, without which it could not occur.'

"The misconception has, no doubt, arisen from my using in the same paper the Clausius-Williamson hypothesis of the interchange of atoms among the molecules to account for the difference of pressure in different directions in the electric field. But

*The position of the Stock Insurance Companies is merely advisory upon this clause.

this hypothesis is not essential to the theory of the *discharge* given in the paper, for on that theory the discharge does not take place until *ordinary* dissociation of the molecules is produced by the electric field. The existence or non-existence of the quasi-dissociation of the Clausius Williamson hypothesis which does not produce any chemical effects, does not affect the theory of the discharge, though it does that of the inequality of pressure.'

THE CAPE MAY CONVENTION.

Promise of a Very Successful Meeting.—The Special New York Train.

August 17th, 1890.

Should this letter meet the eye of any electric light delegate who may be undecided whether to attend the Convention or not, I trust that what I may be able to write in the few minutes at my disposal may turn the scale in favor of a visit to this, the queen of watering places. Let him cast his eye over the list of the names of those who came down on the special train, and let me assure him that there are as many more good fellows who came at other times, and I feel confident that we shall have many more names to swell the list:

M. J. Perry and wife.
G. T. Manson "
A. M. Young "
W. L. Candee "
C. H. Barney "
C. O. Baker "
G. E. Barton, wife and daughter.
W. De L. Boughton, wife and child.
W. A. Anderson.
T. McCoubray.
Miss Moran.
H. L. Shippy.
T. A. Perrine.
J. P. McQuaide and wife.
J. A. Seeley.
M. J. Francisco, wife and daughter.
J. W. Godfrey.
H. D. Stanley.
C. W. Price.
O. E. Madden.
A. C. Shaw.
E. F. Peck.
Wm. Brophy.
George McKinlock.
J. A. Wetmore.
A. G. Carner.
Fred. Werner.
C. B. Faben, Jr., and wife.
E. R. Weeks and wife.
G. L. Austin and wife.
C. A. Bragg.
F. W. Royce.
W. D. Morris.
C. I. Hague.
J. B. Taltavall.
E. H. Stevens.

The special train left Jersey City about 2:05 Saturday afternoon under the careful management of our tried friend, Mr. H. M. Haines, who has so frequently guided the convention delegates on similar expeditions. The time was passed in the usual happy way known only to electrical men, and the presence of so many ladies added much to the enjoyment. Cape May was reached about 7:30, and after a hearty supper set forth by mine host, Mr. Theo. Walton, the delegates wandered forth to court the cool sea breezes, and talk over the experiences of past conventions and the prospective pleasures of the one just commencing. Besides the list of those I have given, there are already many more present from all parts of the country, too numerous to relate at present, but I notice more especially Mr. P. H. Alexander and wife, J. M. Orford and wife, D. A. Newton, M. E. Baird, C. L. Tolles, W. J. Jenks, W. C. Bryant, F. B. Platt, A. J. DeCamp and wife, J. R. Lovejoy, and a host of others. To-day the weather is simply perfect, a glorious blue sky overhead, a bright sun tempered by a cool ocean breeze, and a splendid invigorating surf, which thunders ceaselessly upon the white stretch of beach. Many of our friends indulged in a surf bath this noon, and seemed to enjoy to the full struggling in the mighty element, and pounding each other with sand, filling their lungs at the same time with the pure ozone from the Atlantic. Besides, ye tardy delegates, I will let you into a little secret. There is a lovely "convention" of most charming ladies at the Hotel Stockton at present, and from personal experience of my numerous electrical friends, I know that they form a great attraction. It will undoubtedly interest you to visit this entrancing spot, and see for yourselves all the good things provided for your enjoyment. Come and be enlightened, educated, entertained and "ozoned," and you won't regret it.

A. C. SHAW.

PUTTING FIRE ALARM WIRES UNDER GROUND.

The New York Fire Commissioners have sent to the Mayor and to the Board of Electrical Control a reply to the recent letter charging that the wires of the fire alarm service were not being put under ground as rapidly as might be. Superintendent Smith, of the fire alarm service, makes the counter charge that fire alarm wires are interfered with by employés of the Board of Electrical Control without authority, and often to the serious crippling of the service. Superintendent Smith reiterates that his department has been and is doing all that lies in its power to do in the way of putting its wires under ground and in ridding the thoroughfares of the city of its lines.

JERSEY'S NEW TELEGRAPH LINE.

The recently organized New Jersey Postal Telegraph Company is already at work building lines through Newark, the Oranges, Montclair, Plainfield, Rahway, New-Brunswick, and other places to Long Branch and other resorts further down the coast. The company is a branch of the Postal Telegraph Company and the Mackay Cable Company, and promises to give permanent first-class service. Its offices will all be open day and night, and messages will be promptly delivered by uniformed messenger boys on bicycles. The messenger and fire alarm service in Plainfield, where the company has purchased, as in other places, all rights possessed by smaller concerns, has already been revolutionized. The company promises special attention to newspaper dispatches.

CENTRAL STATION STATISTICS OF THE UNITED STATES.

THERE are nominally about 1,500 central stations in operation in this country. A compilation recently made by *Electrical Industries*, of Chicago, brings out the following figures, which are approximately correct, and do not err by overstatement:—

State.	No. of Central Stations.	Capital.	No. of Arc Lights.	No. of Incandescent Lights—16 C. P.	Engine Capacity, H. P.
Alabama	20	$ 4,381,500	2,265	11,510	3,495
Arizona	1	100,000	85	600	60
Arkansas	14	1,005,000	510	12,080	1,900
California	47	11,815,000	7,129	24,540	9,015
Colorado	26	8,000,000	3,029	50,155	8,560
Connecticut	26	3,857,000	3,430	37,477	5,200
Delaware	3	240,000	120	8,100	900
District of Columbia	1	700,000	400	7,000	1,100
Florida	6	245,000	485	3,100	750
Georgia	16	975,000	1,044	7,526	2,305
Idaho	3	70,000	......	2,100	210
Illinois	99	4,890,000	5,942	86,220	20,790
Indiana	57	2,616,000	4,132	15,138	7,805
Indian Territory	2	100,000	85	550	100
Iowa	48	1,750,000	2,179	36,477	6,745
Kansas	62	3,155,000	2,720	38,079	7,270
Kentucky	16	858,000	987	13,050	2,600
Louisiana	7	975,000	1,905	18,400	2,235
Maine	34	1,403,000	2,230	19,158	6,040
Maryland	14	1,735,000	855	20,375	4,660
Massachusetts	85	7,205,000	12,884	132,910	26,000
Michigan	68	3,410,000	6,802	33,332	13,625
Minnesota	28	2,275,000	1,781	37,140	6.830
Mississippi	7	219,000	605	2,650	790
Missouri	34	3,333,000	6,054	56,565	11,135
Montana	9	592,000	825	8,500	1,470
Nebraska	27	1,663,000	916	19,800	4,420
Nevada	2	125,000	190	600	320
New Hampshire	15	880,000	1,764	6,240	4,875
New Jersey	41	2,792,000	4,663	58,580	7,155
New Mexico	1	100,000	52	....	75
New York	135	23,247,000	23,361	259,649	88,785
North Carolina	16	525,000	818	4,283	1,160
North Dakota	6	400,000	289	4,475	825
Ohio	89	5,245,000	10,694	75,696	19,535

VARNISHING THE INTERIOR OF BEER CASKS.

The many accidents which have been caused by the ignition of the alcoholic vapors discharged during the operation of varnishing the interior of beer casks, which arise from the exposure of the illuminant required, can now be prevented. The ordinary lanterns used are now being replaced by the electric light. An incandescent light of small candle power is surrounded by a strong iron frame, which protects the lamp without obstructing the light.

LITERATURE.

Electric Light Fitting: A Hand-book for Working Electrical Engineers. By John W. Urquhart. New York: *D. Van Nostrand Co.* London: $2. *Crosby, Lockwood & Son,* 1890. 226 pp. 5x7½ in. Price, $2.

The number of electric light and power installations has grown so fast that those frequently placed in care of them are perforce taken from the ranks of the ordinary mechanic, and the "engineer" of an establishment is not infrequently put in charge of the electric plant. These men have usually had no practical training whatever in electrical work, and hence any handy book which can convey to them a working knowledge of the apparatus under their charge will add much to their usefulness. On the other hand, many young students about to enter into practical work of this kind would find their toil considerably lightened by a previous knowledge of the precautions necessary to observe in a successful plant, whether a central station or isolated. It is for this class that the author has put together a considerable amount of information which must be characterized as eminently practical and useful.

The first chapter of the work takes up the subject in its general aspects, and, after giving a brief explanation of the various types of machine, series, shunt, etc., and their regulation, brings the reader at once to the practical points to be observed from the time the dynamo reaches the station from the manufacturer until it is set in full running order. Besides important hints on erecting, and connecting up to engine or countershaft, the treatment of the brushes and commutator are gone into at length. We note among the precautions to be taken, where dynamos are transported in parts, a point not generally considered, though of vital importance. Thus it is pointed out that great care should be taken to remove all rust, dirt or oil from the joints between the magnetic surfaces, before bolting the parts together. It is probable that many of the difficulties experienced in starting newly erected dynamos are due to neglect of this simple precaution.

In chapter II. the author continues this part of the subject and enters at considerable length into the localizing of dynamo faults and the tests to be applied for leakage, broken conductors, burned out coils and the various ills to which a dynamo is subject. He points out the necessity for thorough insulation of the dynamo from the ground, neglect of which is the most prolific source of trouble, and usually the precursor of most of the others encountered. The author also treats of the repairs to the armature which may be necessary from time to time, and instances an interesting case involving the restoration of a dynamo to working order, after it had been deluged with water. This was accomplished by covering the dynamos with tarpaulins and applying steam at high pressure beneath them. After several hours of this treatment it is said that the machines were hot and dry enough to very shortly restore the insulation and did not suffer in any way by their bath. It would be well to remark, however, that though a rapid remedy for the restoration of wet dynamos is here pointed out, the cooling of hot journal bearings on a dynamo ought never be attempted by the use of water. The chapter concludes with a description of the methods of installing and operating accumulators.

The switch-board and testing work are treated of very fully in Chapter III., in which the various regulating and indicating devices are gone into at quite some length, and in which the illustrations employed aid the reader very much in obtaining a clear understanding of the text. Besides the various arrangements for running series and shunt machines in parallel, the author also describes a very simple method for throwing in alternating current dynamos in parallel at the proper time and the precautions to be observed in this operation. Here are also described the various tests for insulation, etc., the use of the Wheatstone bridge and the tests required during wiring in order to insure insulation when the work is finished. We notice on page 61 what is probably more an infelicitous expression than an error on the part of the author, who remarks that in discharging accumulators "they should never be allowed to fall below .5 volt." The omission of the word "below" would remove all ambiguity. Arc light wiring and fitting are next taken up by the author, and various types of arc lamps are described, as well as the method of their operation in series, or with incandescent lamps in parallel. Very full information is also given on the methods of running the wires, the insulation and placing of transformers, etc. House installation, including the house main, switch-board, meter and various other important details in this work, are thoroughly discussed. In the planning of a system of mains and feeders the author cites a very interesting method employed by the German Edison Company. The latter employ a large frame or table and make a clear plan thereon of the streets, buildings, etc., to be covered by the system. The location of the central station is then marked, and two wires from a small battery run to it to represent the electric supply. From this point the main leads are all laid down in miniature along the plan of the streets, and each group of lamps is represented by a wire resistance. The current is kept upon the system, and the drop of potential at each point carefully noted by galvanometer. Feeders are then run to equalize the potential, and by means of careful measurement every detail of the system can thus be ascertained. This model network is kept at hand, and as any alterations are required in the real network, they are first made upon the model. This plan has evidently many advantages over the paper and ink system of planning, and it seems worthy of note.

The author also enters very extensively into the description of electric light fittings and their wiring. In speaking of chandelier work, he remarks that a chandelier may generally be made to serve as a return within itself only. This practice, if permitted in England, is discountenanced in this country, where most of the underwriters' rules expressly forbid the employment of the chandelier as a conductor in any manner whatever. We think this rule perfectly justified, and the connection of any side of the circuit with the ground as a decided menace to the safety of the system. The work concludes with a chapter of the incandescent lighting of ships and a variety of miscellaneous information of value to electrical constructors.

The book is very well illustrated and printed, and has so many merits that it would be invidious to call attention to the slight inaccuracies which occur. The work ought to be in the hands of everyone in charge of an electric light plant, and though based largely on English practice, is to that extent all the more valuable as embodying information not generally accessible in this country.

"PROVING" OHM'S LAW.

In a communication addressed to the London *Electrician*, Dr O. J. Lodge writes as follows:

In one of the circulars issued to the Electrolysis Committee of the British Association, viz., that dated June 24, 1886, Prof. Fitzgerald suggested an objection to the complete validity of the theory of the experimental method of verifying Ohm's law with twelve-figure accuracy, devised by Clerk Maxwell, and carried out by Mr. Chrystal; doing so in the following words:—

"There is an objection to this method that I have not seen noticed. Maxwell assumes that you can expand in powers of $\frac{C^2}{S^2}$. Now, if the law were the positive value of $\left(\frac{C}{S}\right)^n$, where n differs very slightly from unity, the method would fail, for the current would vanish both in the numerator and in the denominator of Maxwell's expansion."

Maxwell's Theory is given in the Glasgow volume of the British Association for 1876.

In reply to this communication Prof. Sylvanus P. Thompson says:

The question which is raised by the communication which Prof. Lodge is circulating in consequence of the memoranda of Profs. Fitzgerald and Chrystal seems to need some care in handling, if it is not to increase the obscurity of the subject. If resistance is defined as the ratio of the electromotive force to the current which it produces, then the proposition that the electromotive force, divided by the resistance, gives (numerically) the current, is one which no more admits of discussion, nor needs experimental verification, than do the most elementary propositions of algebra. The experiments suggested by Maxwell, and tried by Prof. Chrystal, and those carried out by Prof. Fitzgerald, important though they are, cannot possibly be wanted to verify or prove Ohm's law. What they do go to verify or prove is, not whether the mathematical relation that bears the name of Ohm is true, but whether that property of an electric conductor which is called its "resistance" is, or is not, a constant. Now, it is common knowledge that the resistance is the function of at least one variable—the temperature; and it is quite a legitimate topic for inquiry, as Maxwell suggested, whether it is, or is not, also a function of another variable, namely, the density of the current passing through it. But why draw the line at these two variables? May it not equally be a function of such variables as the magnetic field in which the conductor is placed, the intensity of the illumination of its surface, the intensity of sound falling upon it, the intensity of the circumambient medium, the slope of temperature between its various parts, and the like? If it were found that the resistance of a conductor varied with any of these, surely one would not say that Ohm's law was false. One would simply say that the resistance was variable, and that if in Ohm's law one wrote the true value of the resistance corresponding to the circumstances, Ohm's law must then truly express the facts.

Now, whether this is granted or not, I invite the attention of the disputants in this matter to the very simple fact that for certain conductors, notably for iron and for bismuth, the resistance which they offer to currents of small density is assuredly not the same as the resistance which they offer to currents of large density, even if the temperature is artificially maintained equal in the two cases. It is known that these two metals—amongst others—when placed in a magnetic field, change their resistance. The fact was first discovered by myself and Mr. C. C. Starling in the case of the metal tin; it was almost immediately afterwards independently detected by Righi; it has been measured by him, and also

by Tomlinson; it has been made by Leduc and others the basis of a method of measuring the intensity of magnetic fields. Of the fact there can be no doubt. Neither can there be any doubt that when a wire of iron, or of bismuth or any other metal carries a current, a magnetic field is created circularly around the wire, partly outside it, also partly inside it. Also the intensity of this circular magnetic field within the metal depends upon the strength of the current. Hence it is *absolutely certain* that the resistance which an iron wire or a bismuth wire offers to a large current, is different from the resistance which it offers to a small current.

But shall we, because we find that resistance is a function of another variable besides temperature, forthwith pronounce Ohm's law false? Surely the more rational mode of procedure is simply to acknowledge that resistance is not a constant.

CORRESPONDENCE.

CHICAGO.

A Large Building and Isolated Plant.—Successful Storage Battery Cars.—An Electric Road Strike.—Mules vs. Motors.

ONE of the largest buildings in the world is to be built in Chicago. It is to be the new Fair building, which will be erected at State, Adams and Dearborn streets. The building will have a front of 190 feet on State street, 350 on Adams and 190 on Dearborn street. It will be of steel construction, the front of stone and terra cotta, sixteen stories high, and cost at least $3,000,000. Forty-three elevators will run in the building. A grand entrance will extend from State to Dearborn street, and another will run from Adams street to the main passage through the building. There will be an open court through the centre. The building is to be fireproof throughout, and will be lighted entirely by a private electric lighting plant, in the construction of which the latest improvements will be installed and no expense spared in making it one of the finest isolated plants in existence.

The report comes from Dubuque, Ia., that the electric storage battery system for running street cars has been tried there with such success that the president of the street railway company has ordered fifteen cars. Parties from Chicago, Milwaukee, St. Paul, LaCrosse and Indianapolis are expected there to witness tests of the system. The trial trip gave entire satisfaction.

The engineers of the White Line Electric Road at Dayton, O., ran all the cars to the north end of the line, last week, and then struck for an advance to $2 per day and demanded the removal of the recently appointed manager, Michael A. Nipgen, who was appointed to bring the employés into better discipline. The strikers grounded the wires and refused to allow cars to be run back to the power house.

A hard fight between mules and electricity is being waged by the street car companies in Springfield, Ill. This city has two street car lines. One is operated by mules the size of jack rabbits and is a narrow gauge affair; the other has recently substituted electricity for horse power. Citizens getting a taste of rapid transit petitioned the latter company to build considerable new road. Work was begun, but the mule line had previously secured a right of way from the city council over the streets on which the electric company attempted to build. There was a clash of forces and there has been war ever since. The electric company has succeeded in getting several miles of track down in spite of the opposition, the citizens along the route doing a good part of the work themselves. The city council decided that the "mule line" had the right of way, but the electric company declined to abide by the decision. The mule line has promised to put in an electric plant and put the road in position for rapid transit at once.

The demand for nine hours made by the machinists of Pittsburgh has gone into effect. At nearly all the shops the demands were granted, but about 500 men are out at shops where the demands were refused. Among the strikers are the machinists of the Westinghouse Machine Co. It is thought the trouble will be amicably settled in a few days.

A noisy debate occurred last week over the order to extend the time for the completion of the John B. Lyon electric railway on Stony Island avenue for one year. Aldermen Hummel and Gorman had some difficulty in getting a vote on their order. It was finally passed.

The disastrous fire which occurred about 6:30 p. m. on the evening of July 30, at the Ed. E. Ayer Company's yard, destroyed between 80,000 and 90,000 poles, making an estimate loss of $200,000, fully covered by insurance. This was the only available supply of poles in the vicinity of Chicago, and one of the largest in the country, and the loss will probably mean a scarcity and higher prices on poles for electrical work in the immediate neighborhood.

CHICAGO, Aug. 15, 1890.

PITTSBURGH.

Lighting a New Theatre.—Street Railway Projects.—An Electric Car Safety Device.

CHARLES L. DAVIS, who is "Alvin Joslin" of the stage, is to manage a theatre in Pittsburgh, next season. Mr Davis is evidently aware of the fact that electricity is the best illuminant for a theatre, and already he has contracted for the fitting up of his establishment with a complete electric lighting system.

Street car projects and rumors relating thereto are just about as plentiful in and about Pittsburgh as will autumn leaves be a month hence in the forests. The latest story is to the effect that the Duquesne Traction Co., which is now constructing a line from the heart of Pittsburgh to the East End suburbs, is desirous of gobbling the two big Allegheny City companies, the Pittsburgh, Allegheny and Manchester and the Pleasant Valley. Each of these concerns covers a large and profitable field. Each is pretty well backed by money and political influence, and it is not at all likely that either will sell to the Duquesne people at a sacrifice. The Duquesne company will have a large business itself, once it gets fairly under way with the running of its cars.

The Standard Underground Cable Company of this city are in a happy mood just now. Their joy arises from the fact that with them business is very active. They are just shipping a big order to Minneapolis and a bigger one to New York City, and many other cities of the country are appreciative of the Standard Company's goods.

The Enterprise Light, Power and Heat Company was organized at McKeesport, Pa., the other day. The intention is to erect a first-class station in Reynoldton, just across the Youghiogheny river from McKeesport. Reynoldton is a rapidly growing town, and is not provided with electric illumination. The officers of the new company are J. E. White, president; Thomas Reynolds, treasurer; L. G. Reiber, secretary; H. H. Swaney, solicitor.

There is considerable talk of an electric street railway between East Liberty and Braddock, to parallel the Pennsylvania Railroad, and of course take from that worthy corporation a portion of its patronage. It will be natural for the Pennsylvania people to look the reverse of smilingly upon this scheme, and they will probably do their best to squelch it. While waiting developments the sympathy of the public will be with the would-be organizers of the street car system, as a matter of course. Accommodations such as the proposed company would offer are ever welcome.

"The adjustable life saving guard for street cars" is the name of a contrivance recently invented by a resident of Pittsburgh named W. Y. Brady. Mr. Brady says his device consists of a series of pliable bars, covered with leather and resting on iron shoes, which when lowered will run close to the ground and receive on it any impediment the car may strike. While there is no claim that the use of this invention would prevent accident, the inventor is very certain that a car provided with it would be very much less likely to cause serious injury to a person or animal coming in its way.

PITTSBURGH, August 16, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

EFFICIENCY OF THE TRANSFORMER.

[134.]—Mr. Swinburne's letter in the Aug. 6 issue of THE ELECTRICAL ENGINEER, with regard to the results obtained by Mr. Merritt and myself and Messrs. Humphrey and Powell, that have been communicated to the American Institute of Electrical Engineers and reported by you, is as kind as it is just.

In determining the instantaneous currents in the primary of the transformer Mr. Merritt and I used the following method: Two lamps were selected to be used in the primary of the transformer and "calibrated" for this purpose by subjecting them to different continuous differences of potential, and observing the corresponding strengths of current that were set up through them. From these observations, then, as data, a curve was determined from which we could read the resistances of the lamps corresponding to any difference of potential throughout the range through which they might be used. The lamps were then used in the primary of the transformer in the manner described in the paper.

When a curve of the differences of potential about the lamps that were caused by the primary currents producing falls of potential through them, was determined, the effective difference

of potential was also observed with the electrometer by connecting it direct to their terminals. This effective difference of potential could also be obtained from the same curve of instantaneous values of differences of potential, the two determinations making an excellent check. Then by reference to the curve of calibration the resistance of the lamps was obtained corresponding to the effective difference of potential, assuming thereby that the resistance of the lamps was the same, whether the lamps were subjected to a certain continuous difference of potential or the same numerical effective difference of potential. The ordinates of the curve of instantaneous differences of potential about the lamps were then divided by this value of the above resistance, when the resulting curve was the curve of primary current. I trust I have thus made clear beyond all doubt what we did.

The correctness of the method then is dependent upon the assumption that the temperature, and, therefore, the resistances, of the lamp filaments remain constant throughout a complete cycle, and from cycle to cycle.

Messrs. Humphrey and Powell, in their thesis work at the close of the last University year, did a large amount of experimental work for the purpose of procuring data that should be checked by students that would come after them, and that ultimately, therefore, would become valuable information for purposes of instruction. They considered the abstract of a portion of their work that they prepared to read before the American Institute of Electrical Engineers incomplete without a determination of cards of static hysteresis, and of hysteresis and Foucault currents combined, at the periodicity the transformer was worked. These cards they produced in great haste, and by them made the deductions to which Mr. Swinburne calls attention, and incorporated the same in the paper. They sent their papers to the secretary of the Institute to be reported and to have copies prepared for the meeting, and then discovered an error in the determination of these cards. It was then too late to remedy the matter. For these reasons then the plates XII., XIII. and XIV., containing comparisons and deductions from these cards in their paper, are erroneous and will be stricken from the authorized report of the Institute.

The hysteresis loss that Mr. Merritt and I found in the core of the 10-light transformer at a maximum magnetization of 3,850 lines per sq. cm. was 3,300 ergs per cycle per cu. cm., while Ewing's values given for very soft wrought iron, at this same maximum magnetization, show a loss of about 1,500 ergs, or, roughly, half what we obtained. It is not clear, therefore, why Mr. Swinburne should say that the loss that we found is small.

The other points of which Mr. Swinburne makes mention seem to me to be open to discussion, and would be difficult to settle definitely without more accurate experimental data than we have thus far been able to obtain.

HARRIS J. RYAN.

SIBLEY COLLEGE, CORNELL UNIVERSITY, ITHACA, N. Y., AUG. 11, 1890.

ELECTRICAL NOMENCLATURE.

[135.]—At the regular monthly meeting of the American Institute of Electrical Engineers, held on June 17th last, a proposal was submitted to advocate the connection of the names of Franklin and Henry with the names of some electrical units, and in particular to connect that of Henry with the unit of self-induction. I venture to think that this proposal deserves attention. The British Association Committee on Electrical Standards committed itself last year to the adoption of the term *quadrant* as a name for a practical unit of self-induction, and in face of the fact that private enterprise had already coined and set in circulation the name "secohm" for that of a practical unit of the same nature. Both these terms involve a departure from the principle first suggested by Mr. Latimer Clark and Sir Charles Bright in 1861, and adopted by the British Association Committee in 1862, of forming the names of practical units out of the surnames of distinguished investigators.

Objection has been taken to the term "quadrant" in that it conveys the notion of *a length*, and that it is not desirable that the name of a unit should convey the idea of its dimensions on a particular system of measurement, which now is, but to-morrow may be replaced by some other mode. I will not discuss the *pros* and *cons* of this point, but limit myself to the suggestion that the practical unit of self-induction in the system of measurement which employs the ampere, volt, and ohm, etc., as units, should be called a *hen*. Henry first actually observed the effect and invented the term "self-induction," and used it in a memoir published in the *American Journal of Science*, in July, 1832; whilst the account of Faraday's investigations on the extra current was not published until December, 1834. Henry has, therefore, every claim to be considered as the discoverer of the fact and the inventor of the name; and in employing this short monosyllable for the name of that practical unit, we shall do justice to his work, and bestow upon the unit a name which carries no suggestion of dimensions, and which is susceptible of being used in such compounds as *microhen* and *millihen*, convenient for subdivisions of the unit. There is nothing to prevent any one from speaking of true *hens*, or legal *hens*, or British Association *hens*, if it is required to be very precise. Instruments for the measurement of self-induction would be appropriately called *henmeters*, and the act of measurement *henometry*. There is more difficulty in recognizing the mode in which to embalm the name of Franklin; but I desire to point out that, if a place should be found for him in our Pantheon of units, there is yet another, namely, Gilbert, who deserves not to be forgotten. With diffidence I offer some suggestions on a magnetic nomenclature which will give opportunity to use them both. We want two practical units: One of magnetic induction, and the other of magneto-motive force (M. M. F.).

It may be questioned whether our time-honored phrase, "number of lines of magnetic force" (or of induction), is entirely satisfactory from a practical point of view. The machinery of tubes of induction, surface integrals, etc., is admirable for its purpose, but it is much more suited to the class room than the workshop.

It is also equally open to question whether the conceptions of magnetic force and magnetic induction derived from ideal visits to imaginary and exquisitely narrow crevasses in magnetized iron, the explorer being furnished with tiny imaginary "free poles" for experimental purposes, are of a nature best suited to assist actual magnetic engineers. Let us suppose all this for the moment set one side, and adopting ideas well expounded by Mr. Bosanquet in the *Phil. Mag.* for 1883, Vol. XV., p. 205, consider only magnetic induction as something produced in the iron by magneto-motive force, just as current is produced in a circuit by electromotive force. Magneto-motive force is produced in a magnetic circuit by linking it with current-turns. Let us dismiss the term "magnetic resistance," objected to by some on the grounds that "resistance" involves ideas of dissipation of energy, and speak of the *magnetic pliability* of a magnetic circuit to indicate its capability of experiencing magnetic induction under impressed magneto-motive force.

Then, further, let it be granted that the total magnetic induction in a magnetic circuit is measured in *gilbs*, and that the gilb is the unit of magnetic induction, one gilb being equal to a hundred million C.-G.-S. units of induction, and being defined by the condition that a uniform rate of change of induction in a magnetic circuit of one gilb per second produces an electromotive force of one volt in an electric circuit linked with it. Let magneto-motive force or difference of magnetic potential along a magnetic circuit be measured in *franks* and let one frank be defined by the condition that a uniform slope of magnetic potential along a magnetic circuit of one frank per centimetre of length produces magnetic induction of one gilb per centimetre of cross-section in that circuit, when that circuit consists of material of unit pliability (permeability).

What is now called "the induction" (B) will be called "density of, or intensity of, induction," and be expressed by gilbs per square centimetre.

The magneto-motive force will be expressed in franks or microfranks, instead of $\frac{4\pi}{10}$ times the ampere-turns (one microfrank = 80 ampere-turns); and the general relation between the magnetic quantities will be that the density of the magnetic induction in a closed magnetic circuit uniformly acted upon by M. M. F. is proportional to the magneto-motive force per unit of length, and to the magnetic pliability of the material of that circuit.

Magnetic pliability is a constant quantity (taken as unity in measurement) for all non-magnetic circuits; but in ferro-magnetic circuits it is a function of the induction or of the magneto-motive force. Tables can be made out from the observations on permeability at various inductions, giving the pliability of different kinds of iron for magneto-motive forces of different magnitudes applied in particular ways.

Suppose, for example, that a ring is wrapped over with insulated wire, and that there are 100 turns of wire on it, and that a current of 8 amperes is sent through it; there are 800 ampere-turns, or 10 microfranks of magneto-motive force impressed on that closed magnetic circuit uniformly. Let the length of that annular solenoid be 100 centimetres. The slope of M. M. F. is $\frac{1}{10}$ microfrank per centimetre. Hence, if the ring is of wood or brass, for which magnetic pliability is unity, we have that the density of induction in the circuit is $\frac{1}{10}$ of a microgilb per square centimetre of cross section. If the ring is of soft iron, proper tables would tell us that the magnetic pliability of soft iron under an impressed magneto-motive force of $\frac{1}{10}$th microfrank per linear centimetre is 1,200 units, and hence that for such iron ring the density of induction is 120 microgilbs per square centimetre (12,000 C. G. S.).

If the iron ring has a cross-section of two square centimetres, and is wrapped over also with 10 turns of secondary wire, and the primary current is completely reversed in $\frac{1}{100}$th of a second, the rate of change of total induction through this secondary would be approximately 480,000 microgilbs per second, and create in the secondary a mean electromotive force of nearly half a volt during the time the uniform rate of change of induction was proceeding.

These rough suggestions will perhaps show that from a practical point of view calculations for dynamo and transformer work might be simplified by the use of such units. The employment of a properly simplified nomenclature for the magnetic units will be a gain, and some such modifications as I have attempted to suggest are wanted for workshop use. One cannot readily teach

workmen to handle formulæ bespattered with 4π and 10^8, μ and B; but the conception of ampere turns (80 of which constitute a unit) wrapped round an iron magnetic circuit, whether dynamo magnet or transformer core, acting to produce a certain density of something called induction (measured in gilbs), more or less according to the magnetic pliability of the material, grafts on to existing experience with electric currents, electric pressure, and electric resistance, and only wants a proper set of units and names to make it adapted for every day use. Perhaps some of your readers will give you their views on these matters.

J. A. FLEMING.

UNIVERSITY COLLEGE, LONDON.

REPORTS OF COMPANIES.

STOCKS AND BONDS.

SHELBINA, MO., has voted bonds for $5,000 for an electric light plant.

SHELTON, WASH.—Mr. W. D. Baldwin, the city clerk, reports that the town will bond itself for $20,000 for electric light plant, etc.

JERSEY CITY, N. J.—Lawrence S. Mott & Co., 115 Broadway New York, are offering $100,000 thirty-year first mortgage bonds of the Jersey City Electric Light Co. 5 per cent. of the par value of $500. The net earnings of the company since January, 1889, have, it is said, enabled it to declare semi-annual dividends of 3 per cent. on the capital stock. The net earnings are steadily increasing, and out of the undivided profits an annual sinking fund of not less than $3,000 is deposited with the New Jersey Title Guarantee and Trust Co.

DIVIDENDS.

HARTFORD, CONN.—The Hartford Electric Light Co. has declared a semi-annual dividend of 3 per cent.

FINANCIAL MARKET.

QUOTATIONS ON ELECTRICAL STOCKS.

Mr. F. Z. Maguire, Electrical Securities, of 18 Wall street, this city, reports the following quotations of August 9 from New York, Boston and Washington :—

THE FRANKFORT INTERNATIONAL ELECTRICAL EXHIBITION.

Visitors to Frankfort will recall the magnificent Central railway station, situated not far from the city and separated from it by a campagna-like stretch of country. Here is an area of more than fourteen acres of waste land, on which the coming electrical exhibition is to be held. Leaving town by the Kaiserstrasse, electric railway trains will convey visitors to an electrical station situated between the principal building and the river annex. It is intended to apply some water-power in the Taurus forest 10 or 15 miles distant, to turbines of 300 h. p., which the Allgemeine Elektrizitäts Gesellschaft of Berlin, with the Oerlikon Works of Zurich, have offered to erect, with necessary dynamos, etc., on the Neckar river, provided some one else will furnish 108 miles of copper conductor of five millimetres diameter. This will be carried on overhead posts, and afford an excellent opportunity to study and experiment upon the subject of long distance transmission. Electric pumps will be employed to raise from the river the water needed for miscellaneous use; electric boat propulsion will be displayed, as well as every known application to power, light, etc.

METAL AND SUPPLY MARKET.

PRICES OF COPPER, ETC.

There has practically been no change of price in copper during the past week, and there is little to report save quiet and steady buying.

Following are the prices to which margins are being called, compared with those of a week and a year ago, as taken from the official circular :

	August 15.	August 8, 1890.	August 16, 1889.
Straits tin, spot	20.95	20.90	20.15
Straits tin, Nov	20.95	20.90	20.00
Lake copper, Aug	16.85	16.80	12.00
G. M. copper, Aug	—	—	—
Domestic lead, spot	4.60	4.45	3.92½
Domestic spelter, Aug	5.40	5.40	—

SOME "MUNICIPAL PLANT" FIGURES FROM MARIETTA, O.

Quite a discussion has sprung up recently as to the relative cost of electric lighting at Parkersburg, Va. (local company), and Marietta, O. (municipal plant), the two places being only 12 miles apart and operating under exactly the same conditions. The Parkersburg *Journal* gives a neat summary of the statistics brought out, as follows :—"The published reports of the cost of running the electric lights at Marietta, Ohio, for one year ($1,825), and our comments on the same, have called out further comments by the Marietta *Register*, which says :—'But, while the sum of expenses for salaries, repairs, etc., is about $1,850, there are two items, at least, not considered—interest on the bonds and depreciation on the plant. We believe our plant has been carefully handled and not strained. Still, 10 per cent. per annum on such equipments is not too much. It is great for the engine or the dynamo, but not enough for the wire. Add these to this cash outlay of interest and expenses, and it will run the cost up to about or quite $3,600. Parkersburg runs all night; we run to midnight, and not at all in full moon.' Yes; and investigation discloses the fact that Mr. Hancock, the superintendent, worked the first year without pay, and that hereafter he is to get $840 a year. The Marietta plant furnished 1,650 hours of lighting, an average of 4½ hours per day, as against 4,069, an average of 11¼ hours per day at Parkersburg. Marietta also uses city prisoners for handling coal, etc. Taking the *Register's* figures of $3,600 for last year, and adding the superintendent's salary, etc., we get the cost for an average year, for 61 lights (not 67 lights, since 6 were only recently added), at $4,500. Parkersburg has 58 lights, costing $6,264. But this includes $12 a year for each patent mast arm, which the city can drop at the end of three years from date of contract, if it so desires. But taking the cost at $4,500 for Marietta and $6,264 for Parkersburg, and reducing this to the cost per lamp per hour, we find that Marietta is paying 4½ cents per lamp per hour against Parkersburg's 2⅝ cents per lamp per hour. If we properly exempt the mast arm rentals, Parkersburg is paying 2⅓ cents per lamp per hour. This showing for the Parkersburg Company puts quite a different phase on the matter if the Marietta *Register* gives the correct basis to figure on, *plus* the superintendent's salary. Officials of the Parkersburg plant think that, on a fair estimate for expense, the cost per hour per lamp (61 lamps) at Marietta would be 2¾ cents."

IN BED WITH ELECTRICITY.

"We can give a point to New York people about getting their money's worth out of these little movable electric-bulb lights," said a visiting Idahoan the other day to a reporter of the New York *Times*. "Out our way we take them to bed with us. For keeping one comfortable on a cold night they are as good as a roaring fire in a room. Rubber bags, tin boilers and other devices for holding hot water get cold. With the thermometer 40° below zero, as we often have it in Idaho for long stretches at a time, these old-fashioned arrangements would freeze before morning. But the electric bulbs keep one snug and warm all the time. When I begin to get ready for bed I put the light between the sheets. By shifting it about every little while it takes the chill from the bed by the time I am undressed. As I slide in I push the light down with my feet, and usually fall asleep with it there."

LEGAL NOTES.

THE BRUSH COMPOUND WINDING PATENT ANNULLED IN ENGLAND.

KING, BROWN & CO. *vs.* ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION

In the Court of Session, Edinburgh, on Wednesday, July 16, the First Division disposed of a reclaiming note in the above case. It was originally brought in the Outer House by King, Brown & Co., Rosebank Electric Works, Edinburgh, against the Anglo-American Brush Electric Light Corporation, London and Edinburg, for reduction of letters patent granted to Mr. Brush in 1878 for the exclusive right of making dynamo-electric machines of the compound winding type. Lord Trayner, in the Outer House, found that Brush's patent, having been anticipated by Varley, was invalid, and he, therefore, decided the case in favor of the pursuers, with expenses. The defenders reclaimed to the First Division of the Court and the case was heard before the Lord President, Lord Adam, and Lord McLaren. Judgment on the reclaiming note was given sustaining the action of the lower Court, annulling the patent.

THE GAULARD AND GIBBS PATENT ANNULLED IN ENGLAND.

GIBBS AND OTHERS *vs.* FERRANTI.

In the House of Lords, on July 24, the case of Gibbs and Others *vs.* Ferranti came before the Lord Chancellor, Lord Herschell, and Lord Morris, in the form of an appeal by Mr. John Dixon Gibbs and the National Company for the Distribution of Electricity by Secondary Generators (Limited) from the decision of the Court of Appeal affirming the judgment of Mr. Justice Kekewich, who, on a petition presented by Mr. Sebastian Ziani de Ferranti, ordered that the Gaulard and Gibbs patent, No. 4,362 A.D., 1882, should be revoked.

Their Lordships said they were of opinion that the decisions of the Courts below were correct; and, therefore, they dismissed the appeal, with costs.

DOUBLE CARBON LAMPS.—BRUSH ELECTRIC CO. *vs.* WESTERN ELECTRIC CO.

We are in receipt of the following telegraphic dispatch from the Brush Electric Co., of Cleveland:—"Judges Brown and Ricks, on final hearing, filed an opinion to-day at Toledo, in our double carbon lamp case against the Western Electric Co., sustaining the Brush patent, granting injunction, and ordering an accounting for infringement."

ELECTRIC HAND-LIGHTING GAS BURNERS.—NOTICE ISSUED TO THE TRADE.

The following notification has just been put forth by the Electric Gas Lighting Co., of Boston, and A. L. Bogart, of this city, to manufacturers, users of and dealers in electric hand-lighting gas burners:—

You were notified on or about May 10th, 1888, of the acquisition by the undersigned of certain U. S. Letters Patent for Electric Hand-lighting Gas Burners, and of the commencement of certain suits against specified parties to establish the validity of said patents, and you were warned against infringement thereof, and that infringers would be exposed and prosecuted by the undersigned jointly.

This is to further notify you that in the first one of said suits to be decided, being the suit brought by us against the firm of Fuller, Holtzer & Co., in the U. S. Circuit Court, Massachusetts, upon U. S. Letters Patent, No. 225,071 to Packard, and No. 232,304 to Sanford, wherein the defences of want of invention and non-infrigement were thoroughly presented to the Court, a decree was on May 2, 1890, ordered for complainants, and an application for rehearing therein was, after full argument, on August 9, 1890, denied by the Court.

It has now been established that Electric Hand-Lighting Gas Burners, having a fixed electrode, a ratchet upon the valve-stem, whose teeth are proportioned in number to the ways in the cock, an angle-lever fitted loosely upon the stem, one arm for operating, and the other carrying an electric contact point past the burner-tip, a pawl attached to the lever, and engaging with the ratchet, a spring to retract the lever when released, and a stop-pin; and Electric Hand-Lighting Gas Burners having devices for opening and closing the gas passage at each alternate movement, and conjointly igniting the gas by an electric spark thus generated, with further devices which, without actuating the gas-cock, shall repeat the electrical spark by the return of the opening devices to their normal position, are protected by Letters Patent owned by the undersigned.

The trade is respectfully cautioned that all infringers will be held to account and pay damages.

INVENTORS' RECORD.

Patents issued August 12.

Alarms and Signals:—*Signal*, W. C. Paul and O. D. Kleinsteuber, 433,959.

Conductors, Conduits and Insulators:—*Electric Conductor Terminal*, C. A. Lieb, 433,948. *Machine for Covering Insulated Conductors with Lead*, L. W. Tracy, 434,007 and 434,008. *Underground Electric Conduit*, F. G. C. Zöpke, 434,076. *Electric Insulator*, J. K. Dunbar, 434,144. *Subway for Electric Conductors*, G. Westinghouse, Jr., 434,165.

Distribution:—*System of Electrical Distribution*, O. B. Shallenberger and H. M. Byllesby, 434,162.

Dynamos and Motors:—*Vertically-Adjustable Dynamo Support*, T. Wrigley, 434,011. *Rotating Part of Dynamos and Motors*, E. A. Sperry, 434,096. *Armature for Dynamos*, A. Schmid, 434,206.

Lamps and Appurtenances:—*Automatic Electric-Lamp Hanger and Switch*, O. B. White, 434,088. *Incandescent Lamp Socket*, P. Lange, 434,158 *Incandescent Electric Lamp*, A. L. Reinmann, 434,159. *Electric-Arc Lamp* W. E. Cady, 434,175.

Measurement:—*Ammeter and Voltmeter*, G. Pfannkuche, 434,082.

Medical and Surgical:—*Electro-Therapeutic Appliance*, G. Monrath and W. M. Gibbons, 434,024.

Metal-Working:—*Method of Welding Metals by Electricity*, H. E. Fowler, 434,017. *Method of and Apparatus for Burning Holes in Metal*, W. P. Kookogey, 434,188.

Miscellaneous:—*Coin Freed or Actuated Machine*, A. Harris, 434,109. *Cut-Out and Connection for Electrical Apparatus*, C. J. Klein, 434,149. *Switch for Electric Circuits*, P. Lange, 434,151 and 434,152. *Electric Indicator*, P. Lange, 434,154. *Protector for Electric Machines*, L. B. Stilwell, 434,163. *Core for Electrical Apparatus*, C. A. Terry, 434,164. *Electric-Arc Interrupter*, A. Wurtz, 434,166. *Lightning Arrester*, A. Wurtz, 434,167. *Safety Fuse for Electric Circuits*, A. Wurtz, 434,168. *Electric Safety Fuse-Box*, A. Wurtz, 434,169. *Lightning Arrester*, A. Wurtz, 434,170 and 434,371. *Electro-Magnetic Clutch*, S. C. C. Currie, 434,382.

Railways and Appliances:—*Electric Railway*, R. M. Hunter, 434,080. *Trolley for Electric Railways*, J. H. Wehrle, 434,086. *Brake Mechanism for Electric Street Cars*, J. Illingworth and A. M. Baker, 434,068. *Electric Rail Connector*, C. A. Lieb, 434,087. *Power-Gearing for Vehicles*, E. A. Sperry, 434,097 and 434,098. *Electric Railway*, R. M. Hunter, 434,147. *Electrically-Propelled Vehicle*, R. M. Hunter, 434,148. *Device for the Adjustment and Testing of Electric Cars*, T. M. Foote, 434,181. *Electric Railway*, R. M. Hunter, 434,275. *Current-Collecting Device for Electric Cars*, R. M. Hunter, 434,276. *System of Transportation by Electricity in Mines*, E. A. Sperry, 434,368. *Electric Railway*, R. M. Hunter, 434,389, 434,390 and 434,391. *Closed Conduit for Electric Conductors*, C. J. Van Depoele, 434,410.

Secondary Batteries:—*Secondary Battery*, P. Schoop, 434,093. *Connector for Secondary Batteries*, J. K. Pumpelly, 434,199. *Secondary Battery*, H. Woodward, 434,224. *Method of Making Electrodes for Secondary Batteries*, P. Schoop, 434,301. *Secondary Battery*, G. W. Cochran, 434,376.

Telegraphs:—*Printing Telegraph*, T. M. Foote, 434,261.

Telephones and Apparatus:—*Telephone*, E. Davis, 433,981.

EXPIRING ELECTRICAL PATENTS.

Reported by F. B. Brock, *Patent Attorney*, 639 *F street, Washington, D. C.*

Expired in June, 1890.

Car Brake, G. En-Earl, 139,557. *Telegraph Pole*, McCarver, Athey & Jennings, 139,593. *Gas Lighting*, Mueller & Meier, 139,599. *Telegraph* Poles, J. P Tirrell, 139,630, June 3, 1873. *Exploding Apparatus*, G. M. Mowbray, 139,686 *Printing Telegraph*, H. D. Rogers, 139,690. *Gas Lighting*, J. Vansant, 139,692; W. A. Pitt, 139,811. *Thereapeutic Bath*, S. Russell, Jr., 139,819. *Annunciator*, G. W. Shawk, 139,826. *Lightning Rod*, J. H. Weston, 139,841, June 10, 1873. *Thermostat*, J. H. Guest, 139,958. *Fire Telegraph*, R. Carter, 140,011; Wright, Holley & Miles, 140,106, June 17, 1873. *Annunciator*, W. W. Foote, 140,129, June 24, 1873. *Printing Telegraph*, A. A. Knudson, 140,143. *Incrustation Electrical Apparatus*, A. T. Hay, 140,196. *Telegraph Pole*, H. Dodge, 140,255. *Relay and Sounder*, M. W. Goodyear, 140,266. *Regulator*, E. Maertens, 140,287, June 24, 1873.

List for July was printed in THE ELECTRICAL ENGINEER of July 2, p. 25.

Expiring in August, 1890.

Railway Signal, J. G. Smith, 141,604, August 5, 1873. *Railway Car Telegraph*, R. K. Boyle, 141,755. *Automatic Telegraph*, T. A. Edison, 141,772, 141,773, 141,774 and 141,776. *Perforating Telegraph*, T. A. Edison, 141,755. *Relay and Sounder*, T. A. Edison, 141,777, August 12, 1873. *Annunciator*, A. Storer, 141,898 *Relay and Sounder*, H. Van Hoevenbergh, 141,966, August 19, 1873. *Telegraph Pole*, J. L. Chapman, 142,082. *Railway Signal*, H. W. Spang, 142,131, August 26, 1873.

[Copies of drawings and specifications of any patent will be furnished by Mr. Brock, at 15 cents each.]

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

MARSHALL'S CONDENSERS.

Among the standard specialties of the electrical instrument field are the electrical condensers of Mr. Wm. Marshall, rooms 2 and 4, University Building, this city. Mr. Marshall, slowly but very surely, has built up an enviable reputation for his work, and we have ourselves on many occasions seen the quality of his condensers tested and triumphant under the most exacting conditions. His business was at one time limited to the telegraph, but he is now making and selling for telephone and electric light use. Recent orders are for two multiple series, for the Metropolitan Telephone Co., of half a microfarad each, divided in tenths and one microfarad in tenths for Columbia College. He has also received orders from the New York & New Jersey Telephone Co., the Brush Illuminating Co. and many others.

ELECTRIC CONSTRUCTION & SUPPLY CO.

The above company, of 18 Cortlandt street, have constructed a double carbon arc lamp, they report, embodying the principles of their well-known arc lamp for incandescent circuits. A large number of these lamps are now being made, and the company will be ready to fill orders in about a couple of weeks.

RUSSELL JOHNSON'S ELECTRIC LIGHT MOULDINGS.

One of the most familiar of the details of interior incandescent work is the moulding, and it would not be easy to say how many million feet have been made and used within the last seven or eight years. Mr. Russell Johnson, of 459-465 Cherry street, this city, has long made a specialty of the business, and has sold his product in enormous quantities to all the largest consumers. He has been established thirty or forty years in the lumber business, and when the electric lighting industry sprang up and the call came for mouldings, it was natural that he should enter the new field, not so much perhaps by design as by accident. Having thus secured a preemption on the business, he has ever since been actively engaged filling orders for mouldings in a large variety of sizes. Among a few of the installations he has supplied may be named Columbia College, the Metropolitan Museum of Art, and W. D. Rockefeller's country mansion at Tarrytown; as well as the U. S. war vessels, "Chicago," "Baltimore," "Philadelphia," "Yorktown," etc., as well as the steamers, "Venezuela," "Maryland," "Caraccas," and the beautiful Fall River boats, "Puritan" and "Plymouth." Mr. Johnson will send to any address his blue print sheet of sizes and shapes of mouldings, and has recently issued a very handsome wood mounted thermometer, a neat and ornamental reminder to his patrons.

THE SCHEFBAUER SMALL ARC LAMP.

Mr. R. Schefbauer, of Paterson, N. J., has transferred his business and experimental shop to 28-30 Centre street, this city, and there formed a connection with the old and reliable manufacturer, Mr. A. Wirsching, of ticker fame, for the purpose of manufacturing their various electrical specialties in the latter's well appointed establishment. They will operate under the firm name of Schefbauer & Co. They will pay special attention to Mr. Schefbauer's patent electric cigar lighter, which was fully described in our issue of July 30, page 106, and for which they are already in receipt, as a result thereof, of large orders from all parts of the country. Their announcement with regard to this excellent novelty will be found in our advertising pages. The lamp ranges from 80 to 200 c. p., and is extremely economical in its operation. There is a large field and future before it.

THE SHAVER TELEPHONE SYSTEM.

Mr. George Frederick Shaver, the indefatigable delver in the mysteries of molecular vibration, has recently added another improvement to that remarkable instrument, his Molecular Telephone. It consists of a dish-shaped sounding board, to the concave side of which is secured the diaphragm and molecular resonator previously described in these columns. The strain of the line wire is imparted to the arched sounding board, producing an effect analogous to that of the sounding board of a violin. In practice the device adds materially to the power of the instrument, while the articulation leaves nothing to be desired.

Four sub-companies have been recently organized in New Hampshire, with head-quarters at Berlin Falls, Littleton, Bristol and Concord, and exchanges are being erected. The Shaver Corporation are being overrun with orders, and bank systems and trunk lines are being built in many sections of the country. Plainview, Minn., has, it is stated, thrown out its Bell telephones, and is now getting good telephone service over an extensive molecular trunk line system, connecting the varous business houses, etc. The plant was erected by Mr. J. B. Soboleski, agent of the C. & N. W. R. R. at Plainview, who claims that the service is superior to that with electric telephones.

MILLIKEN RAILWAY POLES.

Lemuel Wm. Serrell, M. E. of 115 Broadway, N. Y., tells us he is meeting with great success in selling the Milliken patent pole for electric railways. He says that he recently closed with Murray Verner, of the Verner-McKee syndicate, for poles for the entire city of Buffalo. He has already received orders from the Rapid Transit St. Ry. Co., Newark, N. J.; Troy & Lansingburgh St. Ry. Co., Troy, N. Y.; Essex Passenger Ry. Co., Newark, N. J.; Buffalo St. Ry. Co., Buffalo, N. Y.; Pittsburgh & Birmingham Traction Co., Pittsburgh, Pa.; Passaic, Garfield & Clifton St. Ry. Co., Passaic, N. J., and Jersey City & Bergen St. Ry. Co., Jersey City, N. J. He has taken orders for over 6000 poles during the last three months.

ABENDROTH & ROOT BOILERS.

The Abendroth & Root Manufacturing Co., 28 Cliff street, New York City, find a good demand for both their new water-tube sectional safety boiler and their spiral riveted pipe. The new form of Root boiler is well adapted and very popular for electric lighting and power stations, being a rapid steam generator, economical in the use of fuel and easily managed. We notice that the manufacturers are making some large shipments to Cuba.

THE OKONITE CO.

The large orders recently received by the Okonite Co. have kept their force at their new Passaic factory very busy. This establishment is thoroughly equipped with everything needful for the expeditious handling of a large business, and turns out an enormous quantity of Okonite insulated wire daily. Every facility is availed of by the company for the transportation of its goods, and taking it all in all the future of this enterprising concern looks very promising.

WESTON ELECTRICAL INSTRUMENT CO.

The Weston Electrical Instrument Company, manufacturers of the Weston portable direct-reading standard voltmeters and ammeters, are now thoroughly settled in their new factory, 114 William street, Newark, N. J., and very busy. The demand for these goods is becoming quite general and is due both to their general excellence and the enterprise manifested by the manufacturers.

JAMES J. MURRAY & CO.

The above well-known concern, proprietors of the Murray Flint Glass Works, Trenton avenue, Culvert and Waterloo streets, Philadelphia, report that they are now in full operation for the season of 1890 and 1891, and are producing a great many new features in goods for electric lighting. Philadelphia is not far from Cape May, and the firm would be pleased to have any of the delegates to the convention favor them with a visit.

THE MILL & MINE ELECTRIC EQUIPMENT CO.

The above company, of 95 Fifth avenue, Pittsburgh, has lately been doing a quantity of heavy mine work. It is now increasing its capital from $10,000 to $100,000 to meet the orders offering it, and is in a position to handle mill and mine equipment in a prompt and satisfactory manner. W. J. Burns is president of the company; W. A. Giles, secretary and general manager, and W. B. Giles, treasurer.

TRIPLE SIGHT FEED DYNAMO OIL CUP.

The Wm. Powell & Co., of Cincinnati, have an excellent oil cup in their specialty named as above, and illustrated in their announcement in our advertising pages. It has been found very satisfactory by those engaged in the operation of dynamos. It is not only a sight feed but is very easy and simple to handle, regulates to a nicety, is of neat appearance, and can be started or stopped at will. The company will be glad to send circulars and price lists to any address.

PITTSBURGH REDUCTION CO.

The Pittsburgh Reduction Co., of Pittsburgh, manufacturers of aluminum for commercial purposes, will erect a new plant near Pittsburgh. It is proposed to erect a plant with 10,000 h. p. near the natural gas or soft coal fields. The company at present occupy an iron-clad building 75 x 175 ft., and are running night and day.

A MAMMOTH SUPPLY HOUSE.

The slow but steady growth which has brought so many of the leading houses of to-day to the front sometimes seems to be eclipsed by the sudden arising of a new firm, which stands up, broad-shouldered, and in a few months gets a firm footing.

Yet the suddenness is only apparent, for the men back of such an enterprise must have been many years in gaining their experience which would enable them to hold their own and gain ground in the face of strong competition.

So it is with the young giant in the electric supply line, which, at the end of but a few months, commands the trade of a large share of the Western and Southern consumers. The step from the small yet influential supply house kept at 80 Adams street, Chicago, by Mr. Geo. Cutter, to the Great Western Supply Co.'s mammoth house at 190 and 192 Fifth avenue, was indeed an enormous stride. The more so as this is but one of the eight or more supply depots which will be controlled by this firm, while several large factories will give in their whole output. Yet a glimpse of the working of this firm will show that the master hands are up to their task, and that the routine of business is almost as smooth as with the older competitors. Truly a trip through such a house means a glance at the electrical business of to-day, or, rather, of the future, and has been duly appreciated by hundreds of our Western readers. We owe it to those not so near to Chicago, that we give them some idea of this house in our columns. The selection of a building for the Chicago house could hardly have been improved upon, both as to its location and as to the space, light and accessibility. Right in the middle of the block, between Monroe and Adams street, the electrical signs and window display on a double front building will attract the attention of the many passers-by. The 42 feet front gives ample window space, where the borders of colored and opalescent glass shades, the assortment of switches, batteries and small motors, as well as some electric light and railway goods, may be shown to advantage. The five high stories, with large windows in the front and back, give light and airy floors, and room for plenty of shelving.

The location is one that makes it the most accessible of Chicago's electric houses from any of the depots. Besides, it is but a block from the other great electrical beehive, "The Rookery," and but three blocks from the Chicago Electric Club. This, with the usual telegraph and telephone facilities, seems to make it convenient for everybody electrical.

On entering the store, any one of the number of novel features is apt to so catch one's eye that others of equal attractiveness may be passed by. To the left, near the door, is a large sample board setting off the brands of wire, as well as some of the choicest house goods. The double row of deep drawers extending along the south wall is surmounted by some four hundred pigeonholes, now mostly filled with small lots of the varied stock.

In front of these compartments is a line of some fifty feet of show cases, at present filled with station and linemen's tools, house goods and testing apparatus.

The oak railing shown in the foreground in our cut, gives a clear space for the managers of three departments and their assistants. The fan-motors shown on their desks give any desired amount of circulation, enabling the same amount of work to be done on hot as on cold days. Above this enclosure hangs a large elk-head electrolier, consisting of three deer heads, the tips of whose antlers are studded with incandescent lamps. A special form of attachment was devised for these, and the wires are practically concealed. Neat tinted shades add to the effect, which is as pleasing as it is novel.

A good part of the ceiling has parallel iron pipes run lengthwise of the store, a few feet apart. From these the electric and combination fixtures are suspended. Here are fixtures varying from plain electric pendants to large chandeliers, and representing the finest American and European designs. Toward the farther corner a hundred brackets set against a dark background are shown to advantage. Here, too, are several new and handsome designs of fixtures for electric car lamps, to which but little attention has heretofore been paid.

Beneath the brackets are sliding racks for incandescent shades, arranged to show a large number in a small space. The partition in the background of the cut separates the store from the shipping room, which, like nearly every other part of the building, is fitted with shelves and bins for storing goods. Here are thousands of the Bryant switches, yonder are bins filled with the Cutter porcelain cut-outs, while in the corner the freight elevator is in steady use.

In the basement one meets with hundreds of reels of Simplex and galvanized iron wire, while one wall is lined with cross-arms of various sizes. In the farther corner is a long shute, lined with iron, down which the reels of wire try their experiments in rapid transit. At the same time the elevator can be used for taking wire up, thus making the receiving independent of the shipping department. Incandescent lamps light up the rear of the basement, the building being wired throughout with Simplex T. Z. R. wire.

On the second floor are the offices of the company, of which our bird's-eye view shows a portion. They are conveniently arranged and handsomely finished in antique oak, with inlaid floors and chipped glass windows. The desks, cabinets and other furniture are all picked to give the greatest usefulness, and here the originality of those interested has been given full play.

Our illustration shows a glimpse of the manager's office, adjoining, while on the one hand is the stenographers' room, and on the other a private labratory where tests of various kinds are made. To the right are the bookkeeping room and the purchasing agent's office, with the directors' room and the clerk's room in the background. Handsome electric fixtures will soon adorn all these rooms, while an abundance of wall sockets enable lamps to be placed anywhere.

The rear of the same floor gives room for many hundred miles of K. K. wire, and also has a studio fitted up for photographing the new designs of fixtures, shades, etc., brought out by the firm. Close by the stairs is another space devoted to shades and arc globes of all styles. The third and fourth floors are used for storing goods, plenty of shelving and drawers being provided. The racks on the latter floor are said to contain the largest stock of shades in the West, and other lines of goods seem to be equally well represented.

On the top floor is the repair shop, and here, too, some of the company's specialties, like Cutter's street-hood or porcelain cut-out, are put together. This shop, added to the out of town factories controlled by the firm, enables it to make its own specialties in any quantity. What some of these are our readers will have already learned, for in its short career this house has brought out a number of articles which promise to stay.

As to the personnel of the new house, the manager, Mr. Geo. Cutter, needs no introduction to our readers. His twenty years experience in America and in Europe has given him a broad view of all electrical work, and enables him to judge well of the electrical supply line. He is assisted by Mr. Rea Pixson, who also acts as purchasing agent for the new firm. Mr. Charles G. Armstrong, well known from his connection with the New Haven Clock Co., and with the electrical work at the Auditorium, and for his numerous inventions, is at the head of the house goods department. Mr. Edwin R. Crolius, late of Sneider, Campbell & Co., has charge of the fixture department, while Mr. C. A. Robinson, buyer of the late Sprague Electric Equipment Co., takes special care of the railway supplies. Others of equal experience are directly or indirectly associated with the house, enabling every part of the work to be properly cared for.

SOME NEW WESTINGHOUSE PLANTS.

When the spirit of progress strikes a town, it is not long content without an electric light plant. Electric illumination is deemed a necessity wherever commercial activity is found. The South, as everybody knows, is developing rapidly at the present time and consequently in that region there is large demand for electric lighting apparatus. The Westinghouse Electric & Manufacturing Company has recently closed contracts for plants in three Georgia towns, Valdosta, Washington and Waycross. It is evident that the Empire State of the South is determined not to be distanced by its sisters.

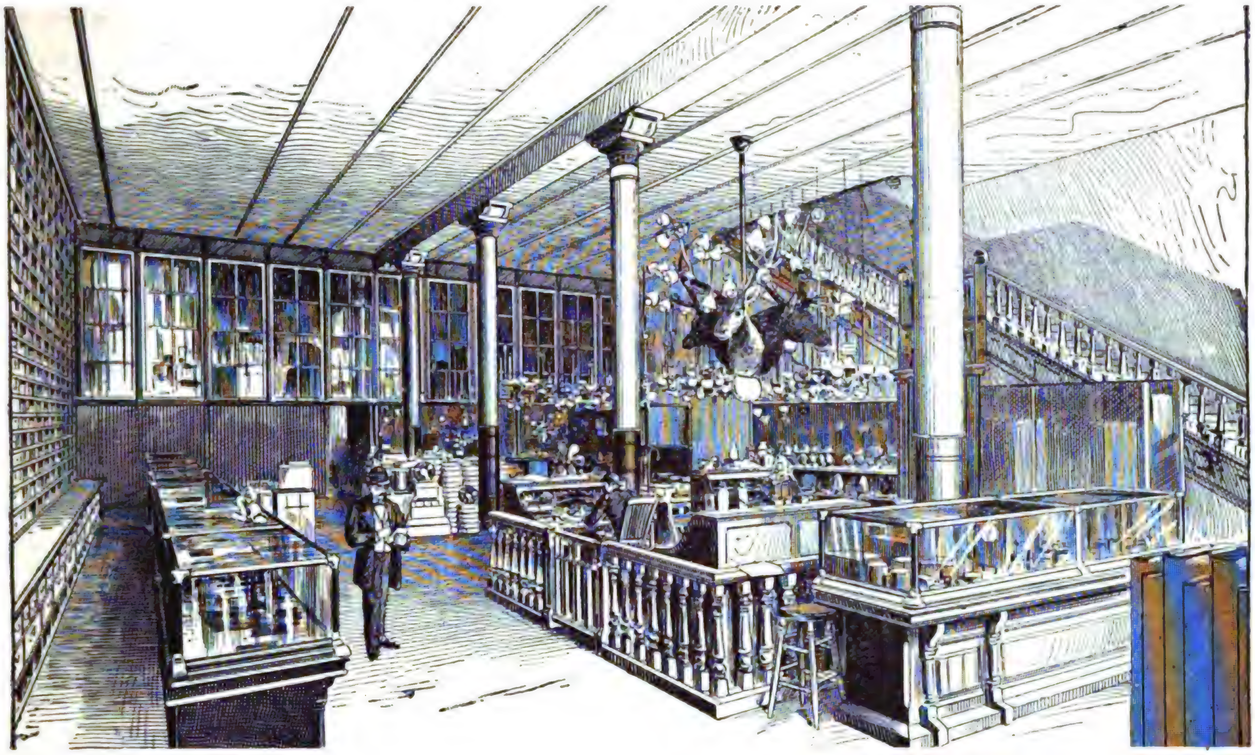
The Allentown Electric Light & Power Company, Allentown, Pa., which for some time has been using the Westinghouse alternate current system of incandescent lighting, has just placed an order with the Westinghouse Company for another machine, it being found necessary to increase the capacity of the plant to two thousand lights.

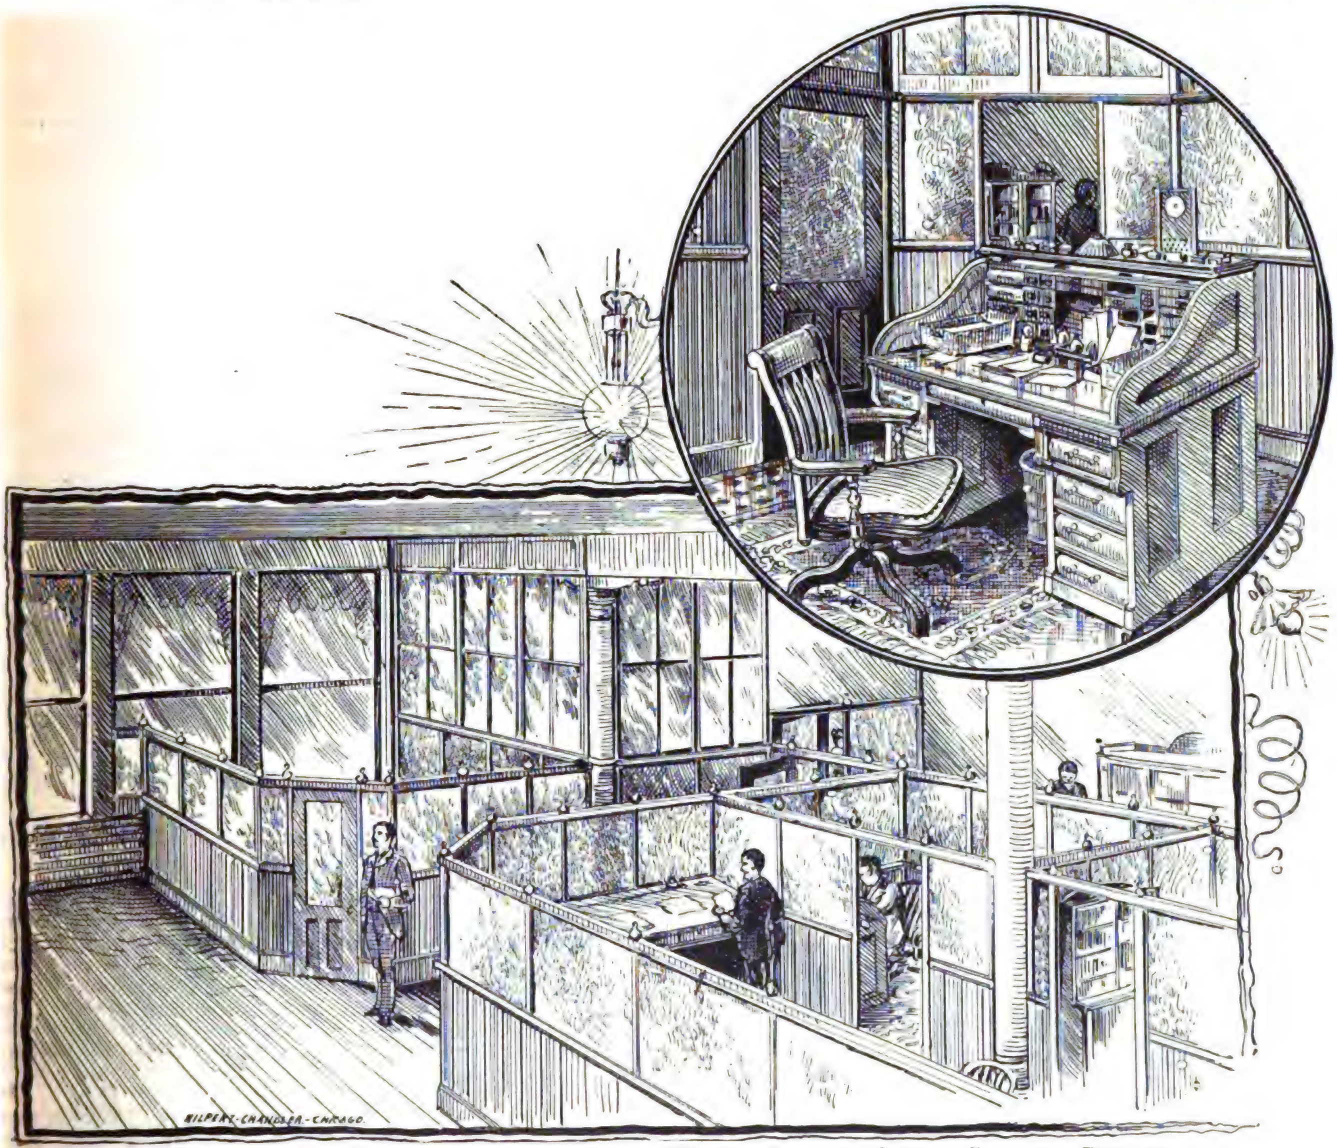
Media, Pa., seems to appreciate the electric light thoroughly. The Media Electric Light, Heat & Power Company has a fifteen hundred Westinghouse alternate current plant and is now ordering an additional five hundred light machine with a view to keeping up with the demands of its customers.

The Westinghouse alternate current incandescent system is being employed for central station lighting in every state and territory of the Union with the exception of the state of Nevada and the territory of Arizona. In the state of Texas, twenty lighting companies have seen fit to adopt the Westinghouse system. In Pennsylvania, the Westinghouse stations number very nearly forty.

JAMES W. QUEEN & CO.

Queen & Co., of Philadelphia, report a steady and increasing demand for their specialties in test instruments. Their improved portable testing sets are meeting well deserved favor, as new features of great value to electricians have been introduced. These sets are being made in large quantities to fill orders already received. The new "Magnetic Vane" ammeters and voltmeters, as brought out by the same firm, are much sought after, and are now in use by the Edison, Brush and Mather Companies. Meters of special size and range are made if desired. A large collection of instruments has been placed on exhibition at Cape May during the convention by Queen & Co., and all who are interested in the subject will be well repaid by a visit to their parlor, where every-one will be welcome.





FIGS. 1 AND 2.—DEPARTMENTS OF THE GREAT WESTERN ELECTRIC SUPPLY COMPANY, CHICAGO.

THE KELSEY RAILROAD SIGNAL CO.

The Kelsey Railroad Signal Co., of Florence, Mass., has equipped the north bound track through the New York Central tunnel from 59th to 86th streets with six audible signals; three one blow indicator signals stationed 300 ft. in advance of home signal locate the latter in case of fog or smoke. The home signals have the company's gong attachment, which rings only when signals are at danger. The company has also finished a very compact three lever interlocking ground machine, built to operate drawbridge lock, home and distant signals, derail switch and switch lock. The machine has also automatic two wire compensator. Its height from floor to to top of signals is 27 inches; width over all, 23 inches.

THE INTERIOR CONDUIT SYSTEM.

The Interior Conduit and Insulation Co., of 16 and 18 Broad street, will issue for the Cape May convention, a pamphlet of testimonials as to the merits of their system. It will embrace endorsements by the various electric light companies, wiring contractors, insurance inspectors, boards of fire underwriters, architects, builders and others. It will also have fac simile letters from J. Pierpont Morgan, E. H. Johnson, T. A. Edison, and Elihu Thomson. It will be quite an interesting book as a description of the system and a pleasant souvenir of Cape May.

EXCELSIOR ELECTRIC CO.

The Excelsior Electric Co., of 115 Broadway, have been experiencing a very large demand for the new Hochhausen arc dynamo illustrated and described in THE ELECTRICAL ENGINEER of April 23. It has proved an immense success in every way. Machines of that type have now been placed in the stations at Kansas City, Kan. (2); St. Charles, Mo., city plant (3); Chicago Arc Light and Power Co.; Plymouth, Pa., Electric Light and Power Co.; Mt. Morris Electric Light Co., New York City; P. J. Walsh, Philadelphia (2); Murphysboro, Ill.; Harrisburg, Pa.; Merchants' Electric Light and Power Co., Chicago; Harrison, N. J., Electric Light Co.; City of Ottawa, Ill., 100 lights, and an increase of 50 more; Osage City, Kan., 50 lights; Duluth, Minn., 50 lights; St. Joseph, Mo., 60 lights, and many more.

The company are also, Mr. Fuller states, extremely busy in their motor department, and are receiving a large number of orders. They are now making a 500 volt motor, which will be ready in about a month, and of which several will be placed immediately. The Excelsior motors are excellent machines, of correct design and high finish, and the reports that come from users are very satisfactory. A great many have already been installed in this city, but a large number are also in service all over the country.

EXECUTION BY CARBONIC ACID GAS.

Dr. Allan McLane Hamilton, who has studied and written since 1873 on the application of electricity to the human body, has, after many experiments, come to the conclusion that electrical execution is a humbug, and openly avows his belief that carbonic acid gas introduced secretly by concealed pipes into a lethal chamber would furnish the ideal of civilized extermination for murderers. "This is the same gas generated for soda fountains," says Dr. Hamilton, "and could be manufactured as easily and inexpensively for the State executioner as for the five-cent soda-water purveyor."

LIGHTING UP THE SEA IN FOGS.

An ingenious invention is described in *Engineering* for distinguishing and safeguarding vessels in fogs. It is based on the fact that when a fog hovers over water there is always a clear space of a few feet between the surface of the water and the bottom layer of the fog. Each vessel is to be provided on one side of its bow, just above its highest water line, with a horizontal row of glazed portholes, and on the opposite side with a vertical row of like holes. Electric lights are arranged to throw beams of light forward and laterally through these portholes, the different arrangement of which is to serve to show the course of the vessel. Sighting portholes, carrying telescopes, are also to be provided close to the former porthole.

THE CLAMBAKE OF THE YEAR.

It has been the custom of the American Electrical Works, through its estimable president, Mr. Eugene F. Phillips, to invite the electrical fraternity annually to a clambake at Providence, R. I., and the notices are now out for the twelfth "clam dinner." The scene of the festivities will be the Vue de l'Eau Club, and the date fixed is August 23, 1890. There will be lunch at 11:30, and the bake will be opened at 3. It is needless to say that the occasion, "rain or shine," will be one of great enjoyment. The Reception Committee are:—Marsden J. Perry, J. J. Carty, H. B. Cram, John I. Sabin E. B. Baker and W. H. Sawyer.

WESTERN TRADE NOTES.

MR. FOREE BAIN, the well known electrical expert and manufacturer, has gone to Kentucky on a short vacation.

THE EXCELSIOR ELECTRIC CO., 425 The Rookery, report the sale of a 100 arc light plant of their well-known system at Ottawa, Ill.

MR. P. C. ACKERMAN, the New York agent of the American Electric Works, of Providence, R. I., was recently in town on a short business trip.

MR. GEORGE H. R. PREBLE, who has been staying here for a couple of weeks and looking up electrical matters with special reference to electric street railway work, has returned to Tacoma, Wash.

THE WESTERN POWER CONSTRUCTION CO. are placing three McIntosh-Seymour standard high pressure engines of 200 normal horse-power each, but capable of developing if desired 300 horse-power each, in the Chicago Edison Company's central station on Adams street.

THE KNAPP ELECTRICAL WORKS are meeting with great success in selling American Electrical Work's line wire. Mr. Myron A. Knapp has gone East, and while away will take in the convention and the cool breezes of Cape May. He will return undoubtedly with many substantial proofs of the general favor in which his goods are held among the electrical fraternity.

THE GREAT WESTERN ELECTRIC SUPPLY CO., 190–192 Fifth avenue, who recently placed upon the market the "Lounsbury" combination pulley and lamp support, have just issued a neat little circular describing it and pointing out the advantages of this very useful adjunct to arc lighting. The mechanism and construction of this pulley was very fully described and illustrated in our columns recently.

J. LANG & CO., 44 Michigan street, Chicago, during the past week have shipped fifteen of the well-known Andrews and Lang switches to various parts of the country. Amongst recent orders they have received for switches are the following:—Six 400 ampere and seven 250 ampere Adams switches for Kansas City, six 100 ampere and six 250 ampere arcs for Chicago; and in Lang switches there are orders for seven double-pole 50 amperes, one double-pole 100 amperes, and ten ordinary 50 ampere ones.

MR. FOREE BAIN, 80 Market street, Chicago, the well-known electrical expert and manufacturer, has just completed an 100 horse-power machine of his new dynamo-motor type. The machine shows excellent mechanical and electrical design and its efficiency is remarkable. The magnetic circuit is so designed that the amount of wire and exciting current are both reduced to a minimum. This machine has just been tested with the most satisfactory results. Mr. Bain has an order for a 200 horse-power similar machine, which will be built right away.

THE CENTRAL ELECTRIC CO. are well fixed for orders and Okonite wire as usual is selling fast. In their handsome offices they have an arc lamp burning with a pleasant and steady light upon the incandescent circuit, and they state that these lamps are highly successful connected in this manner. Near by is one of their globe fans, operated by a Belding motor, which absolutely defies hot waves and maintains a regular lake breeze at all times. In general supplies they are doing a large business, as also with the various specialties which they handle.

THE ILLINOIS ELECTRIC MATERIAL CO., The Rookery, Chicago, dealers in electric light power and electric street railway supplies, have been appointed Western agents for the famous "Canvas Jacket" patent woven-covered insulated wires and cables, manufactured by the American Circular Loom Co., of Boston, Mass. This wire, although but recently placed upon the market, is being received with great favor on account of its remarkably high insulating qualities, and the enormous amount of abrasion that it will withstand. To the peculiar method of applying the covering, these features so desirable in line wire are due. This company has already sold several large lots in the West and fresh orders keep coming in.

THE WESTERN POWER CONSTRUCTION CO., 144 Adams street, Chicago, are installing a 200 horse-power high pressure McIntosh-Seymour engine in the Exposition Building on, Michigan Avenue, to run two large Edison generators for lighting the building, which will be illuminated with some 2000 incandescent lamps. This is one of the recent batch of six McIntosh-Seymour engines sold by this company to the Edison Company. Mr. W. P. Adams, enroute from St. Paul to Boston via Chicago, unfortunately got mixed up in a railway wreck and was delayed at Oneida, Ia. Such trifles as these, however, will not hinder him from being on hand at Cape May, and The Western Power Const. Co. will certainly be ably represented there by him.

EDITORIAL ANNOUNCEMENTS

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. X. NEW YORK, AUGUST 27, 1890. No. 121

The enthusiasm of the inventor and promoter is necessary to progress, and it seems almost to be a law of nature that it should overpass the bounds marked out by reason and experience.—Lord Rayleigh.

THE NATIONAL ELECTRIC LIGHT CONVENTION.

THE Association is in a fair way to win distinction, if not the championship, in carrying out Thomas Jefferson's idea of frequent Constitutional revision. Once in twenty years, we believe, was the period he would have set for an overhauling of the Constitution of the United States. Once a year has now become the practice of the National Electric Light Association. The revision accomplished at Cape May is the third in the yearly series. "Three times and out" is a time-honored saying, but we mistrust its application in the present instance. The motive of the revisions of 1889 and 1890 seems to be entirely just and wise, to wit: to secure the control of the Association and its action to central station men, a class in whose behalf and for whose benefit the Association was formed. That object seemed to be attained by the amended Constitution adopted at Niagara Falls a year ago; which left manufacturers, supply men and all other associate members in the possession of all the privileges of the Association except the right to vote. The Cape May revision diminishes the privileges of associate members by excluding them from attendance at "Executive Sessions," and limiting their participation in other meetings to the discussion of papers read before the Convention. A number of associate members felt that the proposed new Constitution was a direct affront to that class of members, indicating that their room would be more acceptable thenceforth than their company. All feeling of this kind was happily dispelled by the unanimous defeat of Dr. Mason's motion—submitted to gauge the sentiments of active members—striking out the clause of associate members altogether; and later, by including in their privileges the right of discussion on papers.

While it may be doubted whether the Association has yet achieved a satisfactory Constitution, it is quite clear that the owners and managers of central stations in its membership highly value the presence and co-operation of manufacturers, dealers, electrical engineers and others indirectly interested in electric light and power distribution and desire to avail themselves of their knowledge and experience. The Association will, perhaps, hardly throw off its now acquired habit of annual Constitutional revision at once; further attempts to reach a satisfactory status are not unlikely. The amendment offered by Mr. C. A. Brown, abolishing the class of associate members, making all persons now eligible to associate membership eligible to active membership, and providing a veto power in the control of central station men upon all legislative action, may be found to possess some merit as suggesting a method of giving non-central station men a more adequate standing than they now have in the Association, while preserving to the present class of active members satisfactory control of all action. If one-man power be objectionable, the veto might lie with the Executive Committee.

It is to be regretted that discussion was so frequently cut short at the Cape May meeting by resorting to tabling motions, etc. A fair field for all measures on important topics would seem the better policy.

THE SAFETY OF ELECTRICITY.

THE vague and irresponsible statements which have for a long time past been circulated, more particularly by the daily press, have had the effect of instilling into the minds of the uninformed the notion that the employés of electric light stations were subject to greater risks from accidents than those engaged in any other occupation, powder mills and dynamite factories not excepted. All attempts to counteract this feeling of distrust have heretofore been futile, and it is, therefore, a matter for congratulation that the electrical fraternity is now enabled to go before the public with a statement of the exact facts, in the shape of statistics gathered by an insurance company, whose desire to get at the correct figures can not be called in question. The result of the investigation undertaken by the Employer's Liability Assurance Corporation, as set forth in Prof. Morton's paper, read at Cape May, shows that out of 91 accidents reported in central stations only 15 were assignable to the effects of the current, the remaining ones being such as are constantly occurring in power-using establishments. But notwithstanding this excellent showing, the insurance company finds itself obliged, so it claims, to increase the rate of insurance 100 per cent., owing to the fact that people have been wrought to such a state of excitement that unbiased juries cannot be obtained. This hardly seems to us a valid explanation, in view of the fact

that the company has devised a set of rules which, if strictly carried out, would, as Prof. Morton shows, have prevented even the few accidents that did occur. When, as instanced by one of the members during the discussion, five years' operation of his station had not produced a single accident referable to the current, it is certainly a hardship to be subjected to an increased premium. It is to be hoped that the insuring company which has undertaken to exploit this field will recognize the unjust discrimination, and we incline to believe that the course taken in the future will be modeled to a large extent after that of the fire companies, and result in actual concessions to the employés of electric light stations conforming to, and strictly drilled in, the observance of the standard rules of safety. If this point is not reached, the electric light and power business will found an insurance agency of its own for the men engaged in it.

ELECTRIC MOTOR RATES.

In his admirable paper presented before the Cape May Convention, Mr. H. L. Lufkin has touched upon a subject which is of the highest importance to the managers of central stations at the present time. Comparatively few of those who are to-day renting power have had the time to make an accurate study of the conditions which obtain in various manufacturing or trade establishments, relative to the average amount of power consumed. The instructive diagrams accompanying Mr. Lufkin's paper bring this out very clearly and show particularly the relation between the power actually employed in driving the machines and that wasted in friction. Here is a subject which, though pointed to before, has not yet received the attention to which its importance entitles it. As Mr. Lufkin shows, five-eighths of the average power developed by the motor is employed solely in overcoming the friction of shafting. It, therefore, becomes a question of a very simple calculation to determine the point at which a number of individual motors and lines of shafting can be operated more economically than a single large motor constantly driving the entire shafting. It is not at all improbable that such a calculation might even demonstrate the superior economy of driving each machine by its own motor directly attached. The rate to be charged for motor service is often a puzzling problem for central station managers, who, as a rule, desire to be just to their customers, but are often confronted with the uncertainty of the factors which are clearly brought out in Mr. Lufkin's paper. Of course, local conditions must to some extent modify rates, just as in the case of lighting, but the relations which exist being known, an equitable basis for motor rates may now be said to be within the reach of computability by every station manager.

SOME MUNICIPAL LIGHTING FIGURES.

The paper presented before the National Electric Light Association by Mr. M. J. Francisco, on the fallacy and inaccuracy of the arguments and figures offered in behalf of the municipal ownership of lighting plants, was one of the best the Association has ever listened to. The objection that in one or two respects his data was not quite right or fair, might be allowed to stand, and yet his analysis would be in the main thoroughly true and unassailable. He has the best of the discussion by long odds, and the general circulation of his paper, as proposed by the Association, will do much to inform the public on a subject about which so many absurdities are put forward by the advocates of municipal ownership. We do not suppose that towns and cities will stop buying plants immediately, but we do believe that they will be the more ready and likely to give encouragement to private capital and the development of local enterprises. As a piece of educational work, Mr. Francisco's paper was excellent, and it will bear good fruit.

Magnetic Units.

The resolution passed at a meeting of the American Institute of Electrical Engineers to designate the unit of self-induction as the "henry" has met with general approval in this country, and we are glad to believe also that there is a sentiment abroad in favor of commemorating Henry's name by applying it to a unit. We are strengthened in this belief by the perusal of the letter of Dr. A. J. Fleming, in our last issue, in which he clearly points out again the true position which Henry occupies as a pioneer, and as the discoverer of the phenomena of self-induction. Dr. Fleming, however, seems to lean, and not without reason, to the contracted form, and would prefer to designate the unit by the term "hen." He shows that the contraction adapts itself very well to combination with prefixes and suffixes, the introduction of which would become necessary in the practical application of the unit; but Dr. Fleming goes still further, and, we think, has sounded the keynote of progress in this direction by adding to our existing nomenclature other terms which at the present time are designated by periphrases. That is, he would assign the term "frank," in honor of Franklin, to the unit of magneto-motive force along a magnetic circuit, and he also makes an original suggestion, that the name of the father of electrical science, Gilbert, be assigned to the unit of magnetic induction, one "gilb" being equal to 100,000,000 C. G. S. units of induction, and being defined by the condition that a uniform rate of change of induction in a magnetic circuit of one gilb per second produces an electro moive force of one volt in an electric circuit linked with it. What is, therefore, now termed the induction would thus be expressed by "gilbs" per square centimetre. The criticism has been made in the past that the adoption of so many new terms would be apt to confuse, rather than to simplify, matters; but we believe that Dr. Fleming places the subject in the right light when he points out, as he does by a very simple numerical example, that the adoption of these terms will do away with the necessity of employing Greek letters used for some of them, as well as the Greek letters standing for constant numerics, which always confuse those who would otherwise be able to apply these formula intelligently. We are thoroughly in accord with Dr. Fleming in the adoption of these new terms as practical helps and as commemorative of the names of men great in electrical science.

ELECTRICAL INDUSTRIES AND THE WORLD'S FAIR.[1]

BY JOHN P. BARRETT.

It has been stated by competent authority that had it not been for the exhibition of the speaking telephone at the Centennial Exhibition at Philadelphia the telephone would have been ten years later in receiving popular recognition and becoming a success. It is well known that the individuals who were nearest the telephone invention looked upon it with distrust, considered it a toy and an invention of no great practical importance. But Sir William Thomson, who was in 1876, as he is now, the recognized authority in electrical science, seeing the telephone at the Centennial Exhibition, became enthusiastic over it and endorsed it so warmly that it directed public attention to the invention and made it an immediate success.

Great as are the interests resulting from the telephone which was first publicly exhibited at the Centennial Exhibition at Philadelphia, the importance of this invention extends beyond the particular interests directly concerned. The public attention attracted by the telephone has stimulated activity in electrical industries which warrants the statement that the exhibition of the telephone marked a new era in electrical progress. The telephone and the relation of the Centennial Exhibition to the promotion of its popular success, is mentioned simply as an illustration of the importance of the World's Fair to electrical enterprises. Fourteen years have passed since then, and in three years more the Columbian Exposition in Chicago will be looked for to exhibit the progress which has been made since that date, and to be commensurate with an industry so progressive as to have absorbed an investment of $500,000,000 in the past ten years. It is not unreasonable to say that there will be more interest in the development of electrical science and in the evolution of the art of electricity as applied to various industries, than in any other one branch of the World's Fair. The rivalry in invention has led the United States to outstrip all other nations in the practical application of electricity. Thus it was that the electrical department of the United States Exhibition at the Paris Exposition saved the United States from complete disgrace; and yet the electrical department of the Paris Exposition was the weakest feature of the entire show. Probably the United States in the Columbian Exposition cannot hope to equal Paris in the matter of its general exposition, but in machinery and in electrical matters particularly we should do a great deal better.

The most striking failure of electricity to play its proper part at the Paris Exposition was exemplified by the Eiffel Tower, which was not only not lighted by electricity, but even had its numberless gas jets lighted by hand, after the old-fashioned way. Then the general lighting of the show was not made a feature, but only a very subordinate affair. The only place where electric lighting can be said to have been a feature was in the working of the colored fountains, an English invention and already rather old, but a fine thing and worth repeating at Chicago, with better facilities for spectators. The next most striking lack of the Paris Exposition was in the matter of electric street railways. It would seem that an exposition in these days should have an organized system of electrical locomotion for carrying a lot of passengers quickly and cheaply from side to side and from end to end of the entire grounds. Paris had a steam dummy going around three sides of the ground, but that was insufficient, and the cars were usually crowded just when people wanted to use them. That, however, was on account of the Exposition being such an unexpected and tremendous success. The only means of electrical locomotion used at Paris was an electric crane running from end to end of the machinery building, very slowly, to give people a chance to see the various exhibits from above, and incidentally some rest and some air.

There was also no organized telephone exchange system at Paris. Considering that the Melbourne Exhibition of 1880 had a telephone exchange in full operation inside the grounds, doing substantial service to exhibitors, as well as to the officers of the Exhibition itself, Paris is to be pronounced behindhand in this respect. There was something done in the American section at Paris, for the offices of that section and for some exhibitors, but it was not very well done, and was on a very small scale. There may have been other similar telephone exchanges at work, but there was no good general system for everybody and in connection with the city.

It is the intention in the following paper to point out some lines in which the exhibition of that branch of industry, in which we are all interested, should be protected and promoted according to the brief consideration which the writer of this paper has been enabled to give the subject.

In the first place, electricity will find numerous applications in the way of actual service in carrying out the plan of the Exposition. By this I refer to the fire alarm protection signaling apparatus, electric lighting, both arc and incandescent, transmission of power, telephoning and telegraphing. The location of the Main Exposition having been rightfully settled in favor of the Lake Front, which is practically in the heart of the city of Chicago, and within five squares of the telephone central office, the fire alarm central office and the Western Union and Postal Telegraph offices, it will be a matter of no serious difficulty to make such connections with the general city electrical service as will give the Exposition the benefit not only of its own special outfit in each of these directions, but also the advantage of its outside connections. Aside from this application of electricity to the utility and necessities of the Exposition, the features in which we are all particularly interested are those which illustrate the progress that has been made in the science and in the art. The success that has attended recent electrical exhibitions, such as the one in Philadelphia in 1884, and the one in the American Institute Fair in New York, give us some idea of what can be accomplished in this direction with the immense multiplied facilities at the World's Fair in Chicago, and with the incentive to manufacturers and inventors which comes from having the attention of the whole world directed to their work.

With reference to telephones, as is generally known, the fundamental patent on the telephone will expire in 1893, and we may expect not only the inventions, accumulated and hoarded by the American Bell Telephone Company for the years that they have had control of the business, to be exhibited at the World's Fair, but also numerous other inventions which will be stimulated by the opening of the field to competition. Thus this feature should be given a much greater consideration, and more attention should be paid to it than in any other previous exhibition. We have seen only the beginning of the growth of the telephone business. This is shown by the fact that in the city of Berlin there are now 18,500 subscribers, and the exchange there is growing at the rate of 3,500 per year. I predict that in the city of Chicago inside of ten years there will be 30,000 telephones in use. Such a great increase in the use of telephones calls for apparatus and appliances, the invention of which will tax the best talent of the country for years to come. Of course, in addition to the historical exhibition, and the exhibition of recent inventions in telephones and apparatus applied to telephony, there will be immense numbers of telephones used in and about the buildings of the Exposition.

The matter of telegraphy also should receive its due share of attention. The different forms of quadruplex, the use of dynamos for furnishing the current instead of batteries, and other inventions in which the recent history of the telegraph is prolific, should each and all be suitably presented. Police and fire alarm apparatus of the latest design and the best manufacture, together with all appurtenances, will attract a large share of attention.

The telautograph, which by 1893 will undoubtedly be a practical success, even if it shall not have ceased to be a novelty, will also come in for purposes of exhibition as well as for extensive practical use.

Motors for driving machinery, furnishing power for various purposes, running street cars, etc., will perhaps be even of more practical benefit than any other application of electricity; while electric lighting apparatus of various kinds will take the lead undoubtedly, as it now does, over all other electrical industries.

It is proposed to connect the two parts of the World's Fair, one situated on the Lake front and the other at Jackson Park, by means of a railroad built out on the lake. The expediency of adopting electricity for motive power on this railroad is at once obvious. Thus the two features of usefulness and exhibition can be readily combined, and in addition to the direct transmission of power, storage batteries could be employed for traction purposes on this road.

It is difficult in enumerating the different departments of electrical enterprise to foresee all of them, and particularly to foretell the relative importance of the different ones three years from the present time. In no field of human activity is invention so active and enterprise so energetic, and when we speak of the different forms of application of this science which are well known at the present day, we all know that we are simply on the threshold of future developments which may be confidently expected. At no time in the history of the world has there been so great activity in any given direction as there now is in the department which we represent, and too much cannot be said with reference to the importance of having adequate facilities in the coming World's Fair to display the various industrial and artistic applications of electricity.

What will be exhibited at the World's Fair will undoubtedly be a revelation to the visitors. It should be the aim of the people having the exhibition in charge, to so organize and classify the exhibits as to present clearly and forcibly the progress of the art and the present state of the art in its various departments. A chaotic exhibition of the products of the different manufacturers would accomplish something in the way of creating astonishment and mystifying the beholder. This is not what is desired. It is desired that the World's Fair, as a whole, and the electrical exhibition, as perhaps the most important industrial feature of the exhibition, be made an education. It is not too early now to lay plans for the proper presentment of electrical industries for this great Exhibition of 1893. The combined intelligence of the men who are to-day pushing forward electrical enterprises, working

1. Read before the National Electric Light Association, Cape May, August 19, 1890.

in harmony, will be able to accomplish great results, results which will surprise all of us. But the element of time must enter into all calculations; especially is this the case with a subject so large and so involved as the suitable presentation to the public of the rapidly growing electrical enterprises in their various fields.

The Exposition should be made just what its name implies, a practical exposition of the progress and advances made in the several branches of the science of electricity, and the exhibits should be so arranged that the various improvements may be seen and be appreciated at a glance. Thus will the real object of the Exposition be accomplished and a saving of much valuable time to the visitor be effected. For it is quite probable that fully 50 per cent. of the visitors to the electrical section will go there with the earnest desire to become thoroughly familiar by practical observation and study with all that has been done in some certain industry, either to aid in carrying on a certain line of study or with a view to select what they may there conclude is the apparatus best adapted to their needs. In either case, time will be an important and valuable factor, and how to enable each visitor to quickly and understandingly grasp the more important details and points of superiority of any exhibit should be the main object of the respective exhibitors.

The usual method followed in the small expositions has been to allot a certain space to each exhibitor and allow him to place therein whatever he may desire to bring to the notice of the visitor. This is a good plan, and one which proves economical in many ways to the exhibitor. Another plan would be to allot space for the various types of apparatus, irrespective of the main display of the exhibitor. That is, to place all telephone apparatus and everything thereto pertaining in close proximity; the same with telegraphic apparatus, arc lighting dynamos, incandescent machines, motors, etc. The carrying out of such a plan will, of course, give two or more separate exhibits to each manufacturer, and thus entail some slight additional expense, both in the matter of suitable furniture, and possibly in the matter of attendance; but all this additional outlay would be more than returned in the excellent results attained, and in the simplifying of the study of any particular type of apparatus, to say nothing of the greater publicity given each exhibit. Of course there will be no objection to an exhibitor reproducing a complete display of all his wares in the space allotted to him for his headquarters, irrespective of the fact that many articles may also be shown in the respective space to which they belong.

As far as possible a complete specimen of every article and every size should be placed on exhibition. For instance, in the line of motors, there should be one of each size, from the smallest to the largest turned out; and so with dynamos, batteries, etc. In the space alloted to the display of testing instruments the show-cases should be placed on a flooring above a foundation made sufficiently solid to prevent oscillation of the needle, or injury to the more delicate parts from vibration or other similar cause. Every article should have a neatly printed card attached, of size uniform in proportion to the character of the object displayed, containing the name of the article, the manufacturer's address, and a brief description of its intended use, the same appearing in English, French, German and Spanish.

At the present time there are about 430 separate companies or individuals whom we can expect to apply for space, many of whom will have but a single article or two to exhibit. But every one of this number will probably defer action until the last possible moment, unless the importance of securing the necessary space and having his exhibit in readiness within the appointed time, is impressed upon him. Some of the manufacturers will have to be coaxed into making exhibits, while others will hesitate on account of the expense entailed. The chief or his secretary must attend to all of this, and must spare no pains to secure not only an exhibit, but the *best exhibit* possible for each manufacturer to make.

Great assistance in carrying out a comprehensive and systematic plan for the Exposition may be looked for in the United States Census, the report of the Electrical Department of which is looked for with great interest.

THE NATIONAL ELECTRIC CONSTRUCTION CO.

The National Electric Construction Company, incorporated under the laws of Maine, have recently opened their offices at 620 Atlantic avenue, Boston, Mass. The capital stock of the company is two million dollars. The following named gentlemen are the officers of the company: General Ben. F. Butler, President; A. H. Sawtell, Vice President and General Manager; Hon. Lynus N. Child, Treasurer; T. Henry Pearse, Dr. Allan V. Garratt, General Manager of the Electrical and Engineering Departments. Mr. F. Z. Maguire, of 18 Wall street, New York, is the financial agent, and is handling the securities of the company. Dr. Garratt, of the technical department, is very well known in electrical circles as a young engineer of unusual ability and experience. He has also gained a wide acquaintance in the discharge of the onerous duties of secretary of the National Electric Light Association. Whatever work he undertakes is done with intelligence and conscientious thoroughness, and it is believed that a bright future awaits him in this new field. He will not want friends to help him realise his hopes.

THE DANGERS OF ELECTRICITY.[1]

BY PROF. HENRY MORTON.

WHEN the development of electric currents, on a large scale and at a small cost, first became possible by reason of the discoveries of Faraday, Wilde, Gramme, Siemens and others, the question of the dangers to life and property attending their use was brought prominently before the public, just as the dangers attending the use of steam, of rapid locomotion on railroads, and of dynamite were brought to the attention of the world when these powerful agencies first left the experimental laboratory of the chemist or engineer to take their part in the ordinary labor and business of life.

In each instance alike there was a class of people who took the narrow and partial view, that if an agency was dangerous it should be excluded altogether from public use, or, what amounted to the same thing, be surrounded with such exclusions and limitations as would rob it of nearly all its capacity for usefulness, and restrict all possibility of advance and development in its application.

Thus laws were actually passed in England on the first introduction of steam, limiting the pressure in boilers to 30 lbs. on the square inch.

The first railroad charter contained a clause limiting the speed of trains to 12 miles an hour, and when a speed of 30 miles was suggested, it was ridiculed in a prominent journal of the day as an idea simply insane, and it was said that people would just as soon be persuaded to allow themselves to be fired out of cannon as to be hurled along at such fearful velocities, which would, without doubt, have the most disastrous effects upon the circulation of the blood and other vital actions.

Some of us can also recollect the excitement produced and echoed in the press on the introduction of dynamite, and the stringent laws regarding its transportation, which in many cases only increased the danger to the public by occasioning its surreptitious conveyance in passenger and ordinary baggage cars.

We shall have to be very young indeed not to remember the great popular excitement brought about by the daily press when electric lighting first appeared in the streets of New York, and when flashes of flame were described as proceeding from a horse that had run against an electric wire.

In all the older instances matters have settled themselves in accordance with the laws of human progress and the diffusion of intelligence, and we now have boilers running at pressures of 140 pounds and upwards, trains going more than a mile a minute, and gunpowder largely superseded by dynamite.

What is more, the accidents and injuries actually produced by these several agencies have been vastly less than those caused by the things which they replaced.

A much smaller number of people are killed or injured by high pressure boilers than by low pressure ones. How rarely do we hear of the explosion of locomotive boilers, which usually carry 140 pounds pressure.

The accidents to express trains are as nothing compared to those occurring with freight trains, and the loss of life and injury to passengers by rail is insignificant in its percentage to the number carried, when compared to similar loss and injury incurred in the days of stage coaches.

The same relation has been found between dynamite and gunpowder, the former having largely reduced the proportion of accidents and injuries as compared with the work done.

Two lessons are very plainly taught by the facts of history above alluded to.

First: The world is not going to be frightened away from a new and valuable source of power by the circumstance inseparable from the very nature of all powerful agencies, that it is dangerous if not adequately controlled; but, on the contrary, will develop the new power to an ever-increasing and, therefore, more (possibly) dangerous intensity.

Second: Intelligently managed and controlled, the most powerful and, therefore, in a sense, dangerous agencies, become the most efficient protectors and servants of man, and not only aid him in his mission of subduing and utilizing nature, but actually protect him in his work.

Without these "dangerous" agencies man would be reduced to the lowest condition of savagery, where he would be at all times helplessly at the mercy of the "elements," or the blind forces of nature.

With them he not only defies and subdues the beasts which would otherwise be his superiors, but even conquers and renders tributary to his comfort and advancement those vast forces which control the entire matter of the universe.

Applying these lessons taught by the past history of the world in parallel cases to the problem of the distribution and use of electricity, we see in the first place that the way to deal with its dangers ought not to be the timid, obsolete way of prohibition, or of unintelligent restriction, such as that which proposed the exclusion of locomotives from railroads, or the limiting of their speed to 12 miles an hour, but the sensible way of providing ade-

1. A paper read before the National Electric Light Association, Cape May August 20, 1890.

quate safeguards to the new power, and with these allowing it to follow its natural line of development and growth into higher and higher ranges of intensity and consequent efficiency.

It is too well known to all to need statement, that the methods thus pointed out by history and taught by experience have not been by any means universally advocated or followed, and that while many have loudly demanded the exclusion of powerful electric currents, the limitation of their intensity to what they suppose to be necessarily harmless ranges, the users of such electric currents have in too many cases neglected the most obvious precautions.

It is only fair to say, in explanation of this latter statement, that this neglect has in many cases been brought about by obstructions thrown in the way of good work by those who were exciting themselves for the total abolition of dangerous currents, and who, like certain "total abstinence" advocates, objected to every mitigation of the evil they attacked, because any such improvement weakened their case against it.

As regards dangers to property from fires, the matter fortunately fell at an early period into the hands of the Board of Fire Underwriters, who, in a judicious and business-like way, investigated the subject and formulated such rules as have proved eminently satisfactory, and have proved that under proper regulations as to good work and means of protection, electricity is by far the safest means known to us for the distributing and development of light, so far as "fire risks" are concerned.

In view of the satisfactory results thus obtained, I regard it as a fortunate circumstance that the other part of the problem, namely, that relating to dangers to human life, has been recently taken in hand by a similar organization known as the "Employer's Liability Assurance Corporation."

This association, after collecting a mass of material from a great variety of sources, has some time since formulated a series of rules for the protection of those employed in erecting and operating electric apparatus involving the use of powerful, and, therefore, dangerous currents. These rules have been examined and approved by several of the managers of prominent electric companies, and so far it would appear as if no accidents have resulted from the use of electric currents where these rules have been followed, and that most if not all the accidents which have occurred would have been prevented had these rules been followed and obeyed.

Having had something to do with the framing of these rules, it is my chief object in presenting the present paper to secure their criticism by those best able to perceive their imperfections, and such suggestions as may lead to their beneficial modification or extension.

I therefore quote them as follows:

First. Do not touch or handle any electric wire or apparatus of any sort while standing on the ground, or while in contact with any iron work, gas or water pipe, or stone or brick work, unless your hands are covered with rubber gloves, and you are provided with such properly insulated tools as have been declared to be safe and in good order by the electrician or other competent officer of this company.

If it is at any time necessary to stand on the ground, or on any surface not insulated from the ground, while handling electric wires and apparatus, rubber boots or an insulated stool should be used.

In moving wires, hanging on, or lying over, electric light wires, lamps or fixtures, use a dry hand line.

Second. Never handle any electric wire or apparatus with both hands at once when this can be avoided, and, if it is necessary to do so, be sure that no current is present, or that one or both hands are protected by rubber gloves or other efficient insulation.

Third. When handling line wires, treat each and every wire as if it carried a dangerous current, and under no circumstances allow yourself to make contact between two or more wires at the same time.

Fourth. Never open a circuit which has been in use without giving notice to the superintendent, or whoever is in charge, of your intention to do so, and at the same time request that the same line be opened at the main station, and kept open until you have given notice that your work on that line is complete.

Fifth. In the dynamo room never go near the belts or dynamos, nor touch any apparatus unless you are fully informed and instructed how to do so.

Tools used by linemen should be provided with insulating handles of hard rubber or other equally good insulator. It is the duty of each lineman to look after his own tools and see that they are in good order, especially as to their insulation.

Sixth. Lamp trimmers and others engaged in the care of lamps must see that the switch putting the lamp in circuit is turned off before they handle the lamp in any way.

Seventh. In construction work, a space of at least 20 inches must be left between the holes for pins on the cross arms, so that a lineman may get to the top of the pole and work without danger.

The same insurance association has collected the authentic records of a number of so-called "electric accidents" or accidents happening to the employés of electric companies. I have now before me the abstracts of 91 such cases.

The first thing that presents itself in looking over this set of abstracts is that very few of the accidents are in any way attributed to electricity directly, but would have occurred had the establishment in question been any kind of a factory where power was being used, or any place where heavy objects were being moved. A few examples will illustrate this, thus:

"No. 1. Whilst steadying with a pike-pole a large electric light pole which was being placed in position, a passing 'low-gear' belonging to the Standard Oil Company ran over ankle."

"No. 2. While assisting in hoisting a stick of lumber from the street to the second floor of electric station, was injured in right foot by having the stick fall upon it."

"No. 9. Was going to dynamo, stepped on iron plate temporarily covering a belt hole in floor. The plate tipped and he fell partly through the opening, injuring himself internally."

"No. 17. Was oiling rocker shaft of engine near fly-wheel; leaned back too far and was struck on head by spider of fly-wheel."

The above are fair samples of the rest, and, in fact, out of the 91 cases but 15 (or about 16½ per cent.) have any direct relation to electricity.

As I have already mentioned, of the 15 cases in which the injury was in any way caused by electricity there are none in which the action would not have been avoided if the above quoted rules had been observed. Thus, beginning with first in order as arranged in the abstracts, all before it having no direct connection with electricity, we have:

"No. 11. While removing the wire from a Brush dial or regulator which had become short-circuited, was slightly burned on two fingers of right hand."

In this case the beneficial effect of rule No. 2 was manifestly expressed, and had the spirit of rule 7 been complied with even the slight injury experienced would have been avoided.

The next in order is:

"No. 20. Was putting carbon in electric lamp which was out of order and failed to burn. Received charge of electricity, which caused him to fall down from step-ladder on to steam radiator. Two ribs broken."

This would clearly have been avoided by an observance of rule 7.

Time will not permit me to quote all the 15 cases, and I will, therefore, only repeat that they would, all of them, have been avoided by a strict observance in form and spirit of the above quoted seven rules or directions.

Of course I do not mean to imply by this that these rules are perfect or complete, but only that they seem to be in the right direction, and to furnish a starting point from which further developments may proceed.

No one having even an elementary knowledge of electricity as it existed 10 years ago, needed or needs to be convinced of its power to do harm where all safeguards are removed, and the occasional declarations of its harmless character which have been uttered can only be accounted for by reference to that combatitive disposition which impels some minds always to take a view in opposition to any which may be expressed, and gives birth now and then to a book or pamphlet disproving the law of gravitation or the solar origin of light and heat. To say this is, however, far from agreeing with the other extremists who would banish electricity from our daily walks and occupations, or place it under restrictions which *might* render it harmless, but which *certainly would* render it relatively useless for the countless purposes in which its efficiency demands its full development.

The true opinion is that which is supported by past experience, and which advocates the fullest developments of power to which this agency can attain, combined with the use of all the means of protection by which human intelligence can protect itself while using to the utmost this potent and, therefore, dangerous weapon in our victorious contest with the inimically destructive forces of nature.

THE OLD-TIMERS' MEETING AND THE TELEPHONE CONVENTION.

The time of holding the annual convention of the Old-Time Telegraphers and the United States Military Telegraph Corps has been postponed from Sept. 10–12 to Sept. 15–17, so that there would be no conflict with the convention of the National Telephone Exchange Association, to be held in Detroit at that time.

EDISON GENERAL ELECTRIC COMPANY.

Mr. J. H. Vail has been appointed Assistant Engineer-in-Chief of the Edison General Electric Co., and has entered upon his duties. It will be remembered that Mr. Vail was the chief engineer of the old Edison Electric Light Co., and his fitness for the new position will be immediately recognized. The appointment gives no small pleasure to his host of friends.

DEATHS FROM LIGHTNING.

Prof. Bidwell, writing in *Nature* of lightning, quotes figures showing that in England and Wales, from 1852 to 1880, the average annual death rate from lightning was considerably below one per million of the population.

MUNICIPAL LIGHTING.[1]

BY M. J. FRANCISCO.

THE electric spark that Franklin gathered upon his key lay dormant for years, until from the fires of genius, guided by the finger of science, there flashed forth the electric light. This has been increased and magnified, until to-day America stands as the exponent of this science, with 300,000 arc and 4,000,000 incandescent lamps flashing like meteors across the continent. Thus has science aided nature in lighting up the streets and highways of our native land, from the shores of the Atlantic, across the snowy peaks of the Rocky Mountains, to the golden shores of the Pacific.

This vast industry, requiring an army of over 300,000 men and an investment of $300,000,000, is the result of American genius and enterprise. Truly we may well congratulate ourselves that we are here to-day as the representatives of this science and industry, which is revolutionizing the world. Not only has the globe been encircled with telegraph symbols and the human voice sent flying across space for thousands of miles, but the ocean itself has been studded with electric lights, guiding the mariner across its waste of waters and flashing its brilliant hues as a welcome beacon upon the weary eyes of many a watching crew, whose vessel was sinking in mid-ocean.

This science, fraught with so much good for mankind, which has put millions of money into circulation and furnished employment to thousands of laboring men and others, is now menaced by men who, posing as economists, desire to use this power for political and other purposes, as well as for their own aggrandizement, regardless of the interest of the masses or the public welfare. The plain English of this movement is municipal control of electric lighting plants.

Who are the great apostles of municipal ownership of electric lighting plants, claiming that municipalities can furnish lights cheaper than private corporations? Mostly visionary, theoretical dreamers. Not one has had a single day's practical experience in the electric lighting business. For example, we were treated to a specious article in the New York *Independent*, purporting to come from a professor of Johns Hopkins University. An examination of the article shows at once that the author has no experience or practical knowledge of the business, and proves to be simply a youth from Omaha, Neb., who has been studying there for a couple of years. He is now told to cry monopoly, and this article is the result. These are the persons who are being used by professed economists, wire-pullers and others as figure heads; who make statements based upon a state of things that do not exist, and use such statements in contradiction of the actual experience of practical men and the best scientists of this generation, who have not only made the subject a study, but demonstrated the same by testing it every night for years.

If a municipality can sell electricity cheaper than private corporations, why should they not manage all other industries and trades of the country? All cities have large amounts of printing done; why not have the city own and run paper mills and printing offices? also street cars, and own mines and sell coal? They also use immense quantities of stone, building material, etc.; then have them run a marble quarry. The tax payers use carriages; let the city build these also. And so on with every industry requiring the investment of private capital. If municipalities can save the tax payer money in controlling and manipulating one industry, why not all? If they can do it cheaper, then every tax payer would receive the same proportional benefit as is claimed for electric lights.

The great argument used in support of municipal control of lighting plants is a list of cities, with what purports to be accounts of the cost of their electric lights, where over half of the expense of the lights has been charged to other departments. Among these are Bay City, Bangor, Dunkirk, Chicago, Ypsilanti, Topeka and Lewiston.

We will examine a few of the claims made as to the cost of lights in these cities.

The City Superintendent of Bay City, Mich., reported that the cost of the electric lights was only $40 per year. The Council of Bay City appointed a special committee to investigate the expense of city lights, and they submitted a report showing that the city was running 137 lights at a cost of $59.42 each per year, not including taxes, water rates, interest or depreciation. Including interest, 5 per cent. on $35,000, cost of plant, taxes and water rates, 2½ per cent., 10 per cent. depreciation, the cost was $104 per year each lamp, running only dark nights. A short time since, during a thunder shower, the city was left in darkness, because the City Superintendent was afraid of burning out an armature if he ran the lights. A gentleman passing an evening in Bay City recently inquired why they did not have street lights, and the answer was "We do have them," and sure enough, at 9 o'clock they started the lights. Still the price charged by electric light companies for first-class service, with lights every night, even when obliged to compete with the rival forces of Heaven's batteries, is compared with such service as shown in Bay City.

1. A paper read before the National Electric Light Association, Cape May, August 20, 1890.

The city of Bangor claims that the average cost of burning light each night is 12⅝ cents; that is $46.23 per year for each lamp. The electrician is paid $78.50 per month, or $942 per year his assistant receives $520 per year; one lineman is employed at $624 per year; two trimmers at $1,248 for the year—making $3,331 for wages of these men, being $22.82 per lamp per year. They run all night, requiring double lamps and four carbons for each and every day, calling for 1,460 carbons per year each lamp for these they pay $13 per thousand, and in addition pay 96 cents per thousand for freight and 5 cents per thousand for cartage from the freight-house, making cost of carbons $14 per thousand, or $20.44 per lamp per year. Allowing $2.97 per year for oil and waste, we find the amount paid by the city for wages, carbons, oil and waste was $46.23 per lamp per year. This is 12⅝ cents per lamp per night, just what is claimed as the entire cost to the city for running their lights. The plant cost $35,000, and this does not include anything for the water power nor for any portion of construction of the dam or cost of its maintenance, or for the station buildings. Interest on $35,000 at 6 per cent., $2,100; depreciation on electric apparatus, 10 per cent., $3,500; broken globes during the year, $130; wall controller burned out, costing $160; 15 lamps broken, repairs costing about $300; damage to mast-arms, repairs costing $100; repairs at station, $500; also $730 paid for coal. Here is $7,520, which is part of the expense of the electric lights charged to some other department, while to get the true cost there must be added to this the repairs to the dam, interest on the cost of the buildings, wages of an engineer when engine is used, cost of new brushes and segments; also taxes and water rent, which the city would receive from a private corporation if running the lights, which at the lowest estimate, would be over $1,000 per year; thus making a total cost to the city of $15,271.86 for running 146 lamps one year, being $104.59 per lamp, and that, too, with water power all the time except for about six weeks.

The favorite place quoted by advocates of municipal ownership is Dunkirk, N. Y. I herewith give the report of the water commissioners of Dunkirk. As a specimen of expert bookkeeping, and a sample of the way accounts are kept by cities, I recommend the plan to all electric light men; for, if you are endeavoring to satisfy your constituents or stockholders that electric lights can be run without money and without price, t cannot be excelled. The report reads as follows:—

"PAID ON ACCOUNT OF ELECTRIC LIGHT.

For linemen's salary	$ 540 00
For fuel	933 24
For supplies	447 60
For labor repairing line	41 42
For repairs on engine and boiler	65 64
For repairs on machinery	99 40
For miscellaneous accounts	14 60
	$2,141 90

"The above statement shows very distinctly that the most sanguine predictions as to the cost of running the electric lights of this city have been more than realized. After a trial of one year and 8 months, the machinery and line are in better and more perfect condition than when first started. The cost of our electric light does not exceed 1 cent per hour for each light."

Here we have a report from the city authorities stating that the entire cost to the city of running 55 arc lights one year was $2,141.90.

You will notice one item is repairs on engine and boiler; also one item for fuel, showing that the plant was steam power, and, what is far better, a style of boilers and engine that ran the entire year, starting and stopping at proper times automatically, without anyone to look after them except a man occasionally to make a few repairs—the coal walked into the furnace without assistance, and no one was employed in or about the station, neither did the plant cost the city anything.

Here is a sample of the reports made by politicians and those professed economists, which shows just how reliable they are. Of course, a man of practical experience and knowing that electric lights do not run without human agency, would look further before accepting such a statement, and when we examine the accounts of the water works we find engineers and firemen paid $3,555; supplies, $449; general expenses under superintendent, $995; miscellaneous accounts, $240; superintendent's salary, $720; interest on bonds, $7,025—making $12,984 additional. Even if only one-third of this is charged to electric lights, we have $4,328 to add to the $2,141, making $6,469 for 55 lights, or $117 each per year. Consistency, thou art a jewel!

Chicago, it is claimed, is the centre of the world, and the only place on this mundane sphere where mortals can be happy, and where life can be spent without thought of money or the hereafter, because their electric lights only cost $73 per year. We admit that Chicago has triumphantly secured the World's Fair, and is now transposing our national air to "Hail, Chicago! happy land." But they have not yet seen the bills for the electric lights as furnished by the city and used on that occasion. When they

do, the city electrician will need to add something more to his stereotyped answers that the cost of city lights "does not include any expenses such as you mention—taxes, water rent, interest on investment, insurance, repairs, depreciation or renewal of plant in general;" neither will it be expedient to charge the wages of the electric light linemen to the fire alarm telegraph department, notwithstanding it works very nicely now, and helps wonderfully to make the cost of an arc light appear small.

Upon investigation of one of their stations of 275 to 300 light capacity, I find that the chief engineer receives $1,200; assistant, $1,030; four firemen, $2,880; six trimmers, $3,240; line tester, $720; three linemen, $2,520; cost of carbons, $3,800; fuel, $12,000; interest, $14,000; depreciation, 2½ per cent., $8,750; oil, waste, repairs, globes, taxes, etc., $7,000—making $57,190 a year expense for running 300 arc lamps, being $190.63 per year per lamp, and this makes no provision for salary of electrician, superintendent, or for armatures burned out or any accidents or damages. With the linemen's wages charged to the fire alarm telegraph department, we can reduce this $2,520. Now, to what other department do they charge the other expenses to reduce it to $73 per year per lamp.

Ypsilanti, Mich., is the Mecca toward which all advocates of municipal ownership turn their longing eyes, and we are informed that the entire cost of a 2,000 c. p. lamp is $23.61 per year, when the truth discloses the fact that Ypsilanti pays $72 per year, only running 18 nights a month until midnight. Wishing to have the views of the prominent authorities of this wonderfully managed city, the following questions were propounded, and I give both the questions and answers.

Q. 1—With your experience, are you in favor of cities doing their own lighting? *A.*—No.

Q. 2—Why? *A.*—Political preferences and frequent changes of management are too expensive. Incompetent engineers, linemen and trimmers kept in place by a committee for political or other purposes; poor carbons, lack of attention generally, grounding of wires, breaking of globes, infringement of patents, constant repairs, etc., make this system expensive and an unknown amount till the year expires. *The wear and tear is immense*, all kinds of complaints and no responsible head is the rule. On the contract plan for light you pay for what you get only, and know what to provide for in the estimate for tax levy.

Q. 3—If your city had the work to do over again, do you think they would do the same? *A.* No.

Q. 4—Has the municipal operation of your plant met all expectations and requirements? *A.* No.

Topeka is another place where electric lights furnished by the city are cheaper than sunlight, and the city jubilant over their purchase. I quote from a letter written by a prominent official of the city of Topeka, which seems to prove that their millennium has not yet arrived. He says: "The agreement for all night lighting was $6 per light per month. We find that the cost of operating the plant of 184 lights for all night has been $11 per month. The agreement further provided that lights should be 2,000 candle-power; all the tests we have made does not show them to be over 500 candle-power. Our lights so far have been very unsatisfactory. My own opinion of the matter is that it would be much cheaper in the end for the city to have contracted with some of our electric light companies here to furnish the city with its lights at so much per light. We would then have known at least just what they would have cost. As it is we have to take our medicine, which is liable to be a very expensive dose. It is a very expensive luxury, and there are so many expenses coming up that we cannot foresee; therefore, I say, when you take everything into consideration, interest on the investment, wear and tear on machinery, dynamos, etc. (the contractors are already building over ours, and they have not run two years yet), consider well before contracting for a plant." Here is the opinion of an honest official who has had experience with a city owning a plant.

Lewiston, Maine, is another brilliant example of municipal ownership. They have a plant of 100 arc lights, which cost the city $15,000. They burn, on an average, 24 nights per month on moonlight schedule, and the Mayor says the actual running expenses are $4,200 per year. Add interest on cost of plant, depreciation, 5 per cent., taxes, rent of water power which the city would have received from a private company; therefore it is costing the city for 100 arc lights, using water power, $7,200, or $72 per lamp per year, while the local electric light company offered to furnish the same lights for $5,760, being $1,440 less than it costs the city to run their own lights; and still it has been advertised broadcast that the cost of arc lights in Lewiston was only 14 cents per night.

I have secured reports from fifty municipal plants, embracing nearly all the cities and towns in the United States owning plants, and find that the cost of these has been $1,511,225; that they are using 3,725 lamps; 12 places running all night and 38 until midnight or on the moonlight schedule; that the average price paid for coal is $2.34 per ton; that the actual running expenses have been $251,194; that the interest on the cost of these plants is $90,691; depreciation at 5 per cent., $75,576; cost of replacing armatures actually burned out, $12,000; taxes city would have received from private corporations if they had furnished the lights, $15,715—making the total expense to these 50 cities of burning 3,725 lamps (two-thirds of them only until midnight) for one year $444,486, or an average cost of $119.24 per lamp per year. In the figures going to make up the cost of plants and the running expenses I have taken the statements and amounts as given by the city officials, but when we are told that the total amount paid for a complete plant of 68 arc lamps, with engines, boilers, dynamos, etc., was only $1,300, and informed that the total running expenses of a plant that cost $12,000 are only $1,100, and in the same communication the statement is made that they pay their engineer and linemen $125 per month, making an annual bill for these men's wages of $1,500, we naturally long for the secret which enables them to settle this amount and pay for repairs, oil, coal and other expenses with an expenditure of only $1,100.

I have statistics from 365 electric light companies furnishing 35,100 arc lamps for street lighting, three-fifths burning their lights all night and two-fifths burning until midnight or on the moonlight schedule. The average cost of coal is $2.76 per ton. The average price charged per lamp for street lights is $118 per year. This is the price when furnished by electric light companies, who have assumed all the risks and liabilities incurred in the business, and who must furnish first-class lights. This is the cost with lights burning every night without a break, as the contract calls for, and necessitating a rebate if lights are out, which would reduce the price paid by the city.

Only one-third of the cities owning plants run them all night, while of street lights furnished by private companies three-fifths burn all night. Lamps all night and every night would burn 4,000 hours per lamp, while the moonlight schedule would only require about 2,100 hours per lamp. The cost to companies, of course, is much more for all night lights than it is until midnight, and had lights run by municipal plants been burned the same length of time as lamps furnished by private corporations the average cost would have been still more, as lights must have burned about twice as many hours.

It will be noticed that the average cost of coal used by municipal plants was $2.34 per ton, owing to the fact that the majority were located near the mines or places where coal was cheap, and the average as shown for electric light companies is $2.76 per ton, owing to the fact that coal was transported long distances, at high rates of freight. Even with this factor against them, it shows conclusively that private corporations are furnishing cities with lights for less money than they can themselves produce them while owning the plant. This, too, with the expense of operating city plants figured as given by the various cities, which their own report shows is incorrect, and less than actually paid.

It is well known that if a private corporation is furnishing municipal lights, when they are out for a short time or are not up to standard, a rebate has to be made, amounting in the aggregate to many thousands of dollars; but you will never see this item deducted when advocates of municipal control are quoting the cost of lights. Neither do they allow the fact of the city's liability for damages and accidents to be developed. If the municipality own the plant they assume these chances, and here is a feature of responsibility which in most States rests upon the individual as well as the city. The property of any citizen can be held for an execution against the town for injuries caused by a municipal plant, no matter if it amounts to thousands of dollars, and thus he might be deprived of his most valuable personal rights and liberties. If electric light companies furnish the lights, they must meet such claims and protect the city from loss, and the court records show that electric light companies have paid heavy damages on this account.

In the reports received from city officials regarding the cost and operation of their lights, one says: "No expenses charged to lighting account." Again: "Lights are not started for an hour after dark." Many say: "Whenever a thunderstorm approaches lights are shut down and city left in darkness." Another says: "Have not had lights for past two weeks, owing to some trouble at station;" while many report wages of employés charged to water department, and others that no account of lighting expenses is kept. Here we have the basis upon which reports are made that the cost to cities owning plants is so much less than it is when private corporations furnish them, simply deceiving the taxpayers by charging part of the cost to other departments, while raising a hue-and cry about the extortion of electric light companies.

No sane or fair-minded man will, with the corruption and fraud practised by politicians at the present day, attempt to prove that it is for the best interest of the taxpayer to place faith in the honest or conservative management of any enterprise which can be manipulated in the political arena for the advancement of the men in power. The histories of New York, Philadelphia and many other cities are samples of such methods and their purifying effects upon politics. Hypothesis and theory may do on paper, but actual results obtained by practical application and experience are the only reliable data upon which to base any statement relating to the cost of street lighting. In every case these have shown, where all the facts are given, that it has been for the best interest of the citizens and taxpayers to contract

with an electric light company for lighting the streets of any city.

Many cities have found by actual experience, after spending a large amount of money, that this is a fact. The city of Greenville, S. C., has sold out its municipal electric lighting station, the purchasers agreeing to relieve the city of all pending liabilities in connection with the light plant. The city has agreed to pay $100 per year per lamp for not less than 40; the agreement to run for 15 years. Negotiations are pending in several other cities for a sale of their plants to the local or private electric lighting company, as they have found that it was impossible to produce the light, when managed by politicians with no interest in the business, as cheaply as could be done by a private corporation whose managers were financially interested in its success.

There is another feature of this business that it is well to consider. Under the authority and sanction of the Legislatures of the States, private capital amounting to millions of dollars have been invested in the enterprise of electric lighting. The benefit that municipalities have received from this capital is enormous, and it is a question whether the private capital thus locally invested under the sanction of the State can be jeopardized and endangered by the action of municipalities, who are subject to and under the control of the State. In England this matter is fully settled, and no municipality can operate its own plant, if by so doing it will interfere with any local or private company authorized by Parliament.

Judging the future by the past, with the mighty strides that have been made in electrical inventions, two years from now the entire apparatus at present owned by municipalities may be consigned to the scrap pile, and necessitate a new outfit costing thousands of dollars. What is to be done in this case? Levy another tax or issue more bonds, and thus load the city with more debts. Electric light companies have already had this experience and I can cite a case where the company paid $4,500 for their dynamos, and, after a little over two years, could only realize $300 from those same machines. Why is this? Simply that improved plans and apparatus have been discovered which reduces the cost of producing electricity, and unless companies can control these new patents they will be stranded in the race of invention.

Consider, then, for one moment the effect upon the business world if to-day it were possible to blot out electricity and electric lights, with all their conveniences, comforts and luxuries; to stop the progress and development of this wonderful science, and shroud America in a gloom that could only be expressed by Bryon when he "had a dream which was not all a dream," and

"The bright sun was extinguished,
And morn came and went—and came—and brought no day,
And all hearts were chilled into a selfish prayer for light.
The rivers, lakes and ocean all stood still,
And the clouds perished. Darkness had no need
Of aid from them—she was the Universe."

THE VALUE OF DETAIL IN THE CARE AND LABOR OF ELECTRIC LIGHT STATIONS.[1]

BY A. J. DE CAMP.

It certainly is a fact apparent to any one who has had the handling of electric light stations that it is essentially a business of detail. The larger items about the business are very easily handled. They will take care of themselves if they are put in the right direction; but there is an infinite number of small things which very materially affect the successful operation of an electric light station. As an illustration of what I mean by that term, I will say that after considerable reflection and dividing the items worthy of care and attention in the management of the business under fifty heads, all of which have to be kept track of, and all of which are a positive and a direct item of expense or income, I find five items which I have had to class as miscellaneous expenses. These include all those items of expense which have a bearing on the business in general, not chargeable to any one of the particular heads under which I have seen fit to group the business. I find that the amount involved in miscellaneous items for the last year, in one company, was about $15.000; the space occupied on the books of the company to cover these small items was twice as much as the whole of the other part of the business. The items there reached from one penny up. There is no doubt but that detail may be carried to such an extent that it becomes burdensome. It may become unprofitable on some particular item, but we can only treat this matter as a whole. In one item of carbons alone the reduction in the expense of the carbon caused after a system was adopted by which they were accounted for on the basis of the inches, there was a saving of nearly fifty per cent. in that item alone.

Another important thing is the matter of discipline, because it is utterly impossible to get the detail part of your business thoroughly carried out unless you have a thorough discipline about your station. The most important item in the whole operation of an electric light station in point of dollars and cents is that of labor and I do not see but what it will always be the case. I remember there was a time when we thought that sixty lamps on an ordinary circuit was a day's work for a man. Now they trim a hundred lamps more easily than they used to trim sixty, and my own judgment is that in the course of time we will work up so that 150 will be no harder than 100.

A custom of dealing with labor, I think, which requires the accounting of every minute of time for which a man is employed, has a very beneficial effect. I think that alone can be credited with a reduction in the pay roll of some twenty-five per cent. A custom has been adopted by me of having a slip furnished to the workman by which he accounts for every hour of service; this gives the man who has charge of him an opportunity of judging for himself whether that man has employed his time properly during the ten hours. In the early history of the business it was the custom of my company to do a great deal of work without charge. That was done for policy sake. The number of men apparently required for the operation of the station was very far in excess of what anybody ever represented it to be or supposed it to be. In looking into it we found that there were two or three men working here, and two or three there, and three or four somewhere else. What were they doing? Well, they were making changes, shifting the position of lamps, they were doing this, that and the other thing. Well, we were going to be through with that and let these men go, we thought. But the fact is they never did go, they hung right straight on all the time. We closed that month and started in the next on the basis of charging for all work. The basis of the charge was mainly for the labor, charged at thirty cents an hour, and all waste materials. We did not charge for anything that would be incorporated into our own property.

At that time, I think, we were running about 350 lights, and when at the end of the month we charged that up and it amounted to over $800. We tried to collect it, but I presume we did not collect more than $200 out of the $800. People demurred and would not pay it. But it brought the thing to an understanding. Now, no work is done after the first installation unless it is to be paid for by our customer, and we get an order from our customers in which they order the work to be done and to charge it to their account. That brought the next month's charges down, and all we had occasion to charge them was something less than $200. There could be no better proof in the world than that very fact that as long as people did not have to pay for a thing they were very free to indulge their fancies.

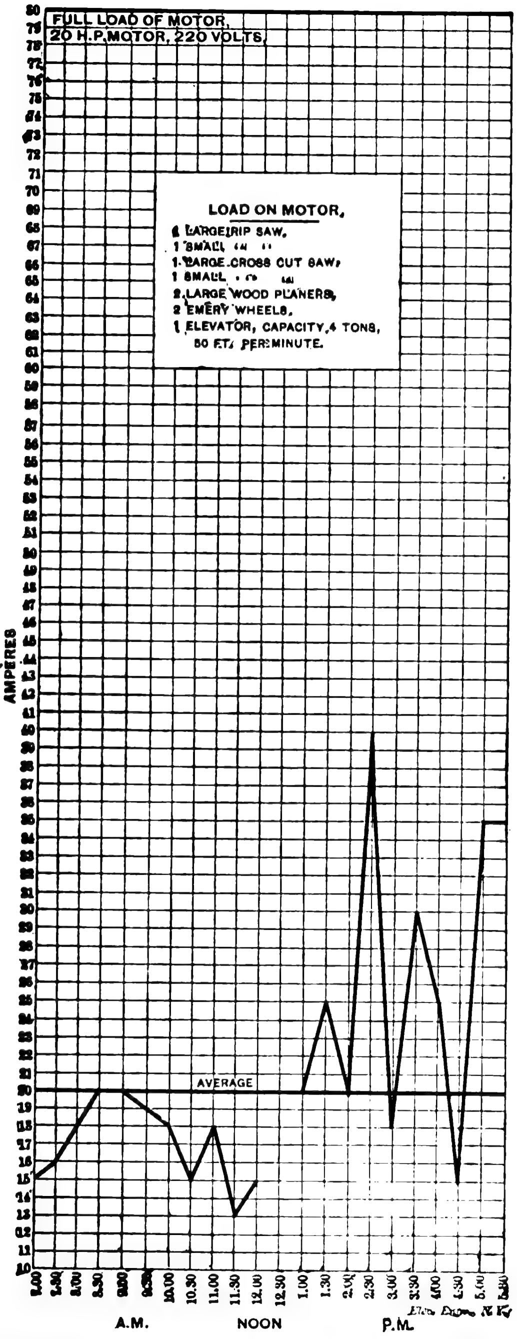
Another point: We send a man out to do a job and he comes in and charges three, four, five, six, or ten hours' time. The man for whom that work is done cannot account for more than an hour or two Then comes your discussion on the payment of that account, and it is a great trouble. We know nothing; we charge a man's time from the time he leaves the station till the time he gets back and reports to us, and whether he has put in that amount of time, less the time of coming and going, of course we have no means of knowing; at least, we did not, but we get nearer to it now. That is one of the things that takes a great deal of time, and I have noticed that our charges for that sort of work are very much more equitable, according to the judgment of our customers, than they have been heretofore; and, moreover, we find that the men do a great deal more work.

Another question which I think can be very profitably discussed is that which relates to small matters of income on your revenue account. The electric lighting business is not in such condition that you can take the ordinary stand and say to the public, "You will take just what we can give you, and just as we want to give it to you, or get nothing." We make our contracts as specific as we can; but we have not got a contract under which we have not given more service than we agreed to give in that contract. The service rendered is never below the standard. We have lights running on the twelve o'clock service plan; and our contracts for that service cover seven hours of maximum burning. That would mean strictly that at no time was the service rendered by those lights to exceed seven hours, which, in the winter months, is from five to twelve. But that does not do, because five o'clock is not early enough in three or four months of the year, when the lamps are sometimes lighted as early as three o'clock. It means rather an average of seven hours than it does a maximum of seven hours. In any city where there is a restriction on the running of wires, it is necessary that you put half night lights on all night circuits with the object and purpose of switching them off, individually perhaps at twelve o'clock. A customer can hardly be relied upon to do that, and the only safe way to do it is to have them switched off by your own employés. It is the same with all night lights which might be run, and sometimes are run. Those conditions must be met. You must give the people what they want, or you will finally lose your business, and you will have to be getting new business all the time.

As long as I have been connected with this Association, and as large an acquaintance as I have among electric light central station men, I never have found any one yet who seemed to have any appreciation or any interest in knowing just exactly what his product cost him on the same basis on which he sold it. To get at the cost of a light, or of any particular part of it, it is very generally figured up as a horse-power. But the point that I have always contended for is this. I rent a light for a given length of

1. Delivered before the N. E. L. A., Cape May, August 20, 1890.

time, for a year, if you choose, which is the most favorable contract that I consider that we can make, because it gives us the longest service. In doing that you figure it on the basis to furnish light 312 nights per year, which you sell at so much per light. Now, you really want to know, not what the 312 lights cost you, and how much you get for them, and take the difference, and let that be profit or loss just as it happens to be, but you want to know just what each one of these lights cost you, and you want to know it as a whole; you do not want to know whether it takes one horse-power or two horse-power, or half a horse-power,

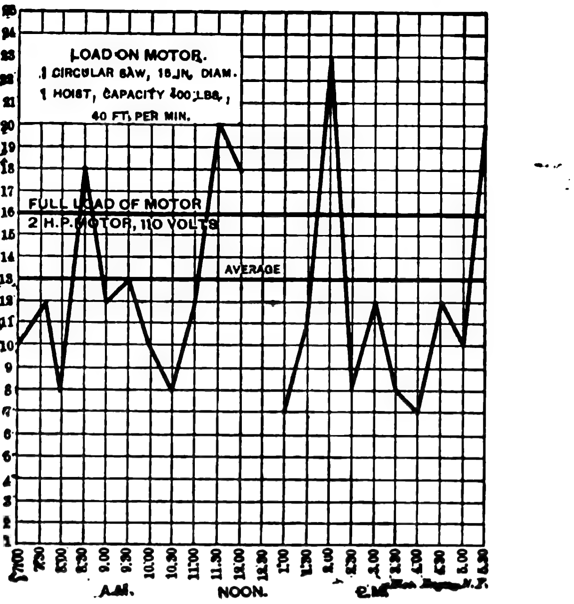


Average Load........................25 per cent. of Rated Capacity.
Maximum Load......................50 per cent. of Rated Capacity.
Average Load........... ....50 per cent. of Maximum Load.
Shafting...............................75 per cent. of Average Load.

No. 1.

as there are a great many other things besides horse-power that enter into this question.

Another thing that I find to be a very common practice is, to have a uniform price for a light of a certain character, whether the contract is for furnishing light for six months or for a year. The same rate for the longer and the shorter term is unjust to your long contract customers. It is a very easy thing to rent lights during six months of the year, commencing the first of September, October or November, and it is a very easy thing to keep such customers, because they want the lights most at that time. But in the summer time people discontinue the use along about the first of March, April, May or June, and so you have an idle lamp during the summer, in which you have your money invested. I contend that the user of that lamp has no right to expect to get that light at the same price per diem as the man who pays you for a service of 312 nights in the year. But that is



Average Load........................81 per cent. of Rated Capacity.

No. 3.

almost universally done. There is just as much reason for a graduated scale of prices based upon the amount of service you get from your customer as there is for fixing the price for a ten o'clock circuit, a twelve o'clock circuit, or an all-night circuit.

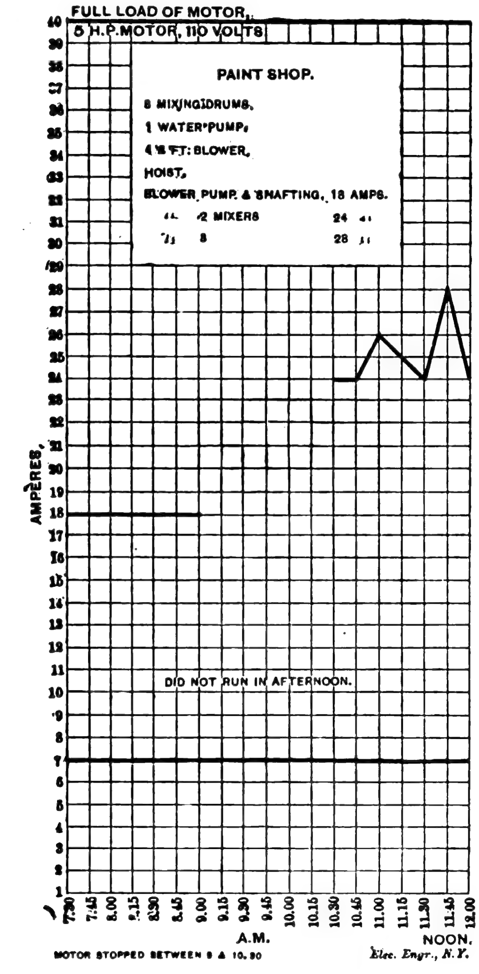
When that first became apparent to me the first effort I made

to equalize the prices on that basis showed me that there was really nothing to go upon excepting guess work. After the first year's experience I had the result of my own experience to go by, by means of which I could work it out in a little better shape. But I found myself doing an injustice to our customers when I thought that I was doing an injustice to myself. I found that I was charging more people too much on that basis and others too little. This puts the company in the position of making a uniform contract in which they can say to every customer, or to every person that comes into the office, that the company will duplicate for him any contract that it has on its books.

A PROPER BASIS FOR DETERMINING ELECTRIC MOTOR RATES.[1]

BY H. L. LUFKIN.

THE equitable adjustment of motor rates, or rather the rates per month, or year, for the supply of current for the operation of electric motors, has long been a matter of considerable annoyance to companies supplying electric power. It is obvious that to invariably charge the motor user an arbitrary rate per horse-power for the motor which he uses, based on its rated capacity, and re-



Average Load......................17½ per cent. of Rated Capacity.
Maximum Load......................70 per cent. of Rated Capacity.
Average Load......................25 per cent. of Maximum Load.
Shafting..........................— per cent. of Average Load.

No. 4.

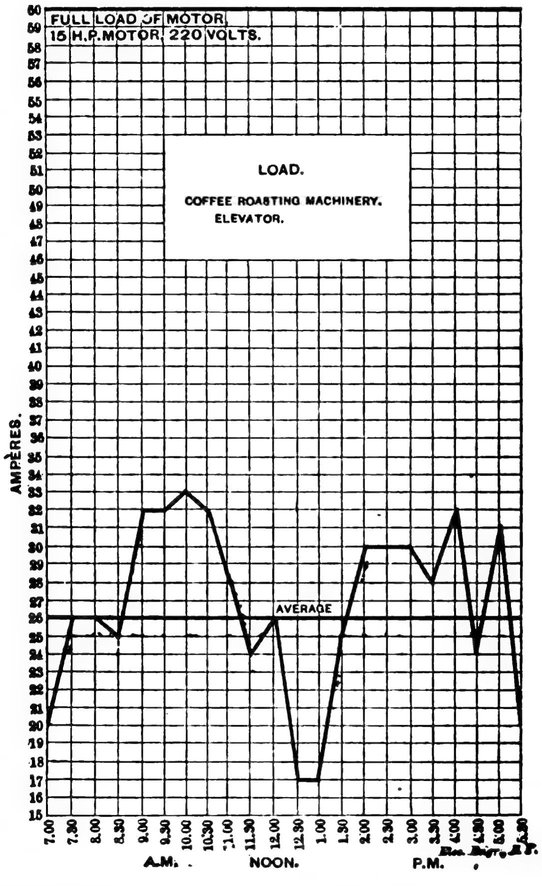
gardless of the work it is doing, is not satisfactory, for the reason that the manufacturer usually prefers to buy a motor somewhat more powerful than his work really requires and thus avoid the possible damage to his motor from overload, or the strain to which any piece of machinery is subjected when constantly operated above its normal working capacity. Again, the manufacturer may contemplate an increase in his plant in the near future, and, in buying a motor, will provide one of sufficient capacity to operate his prospective increase.

To illustrate graphically the practical operations of motors under load, I have taken a large number of records of motors in actual service and from these records have laid out ampere curves or daily load diagrams which will illustrate very clearly the fluctuations in the current supplied to motors in actual practice. Other interesting features of these curves are the maximum, minimum and average readings as related to each other; the current consumed in driving the shafting, as related to the average current consumed; and the peculiarity of the records of motors operating elevators.

Copies of these load records are illustrated in the accompanying diagrams. The vertical lines of these charts, you will notice, represent hours of the day, and the horizontal lines, amperes. In making these records an amperemeter was placed in the circuit in series with the motor and each reading taken was dotted on the chart where the ampere line, corresponding with the reading taken, intersected the hour line corresponding with the time at which the reading was taken. By connecting these dots together with a continuous line we, of course, obtain the diagrams or curves shown.

The highest average use shown in any of these records is in diagram No. 2, with an average use of 81% of the capacity of the motor; this record also shows an overload of 44% at the 2 P. M. reading. Diagram No. 16 shows the lowest average, it being in this case but 24% of the capacity of the motor. A composite average of all these records shows that the average use of an electric motor is but 43.57% of its rated capacity.

It is a fact that many central stations which still use a "max-



Average Load......................43¼ per cent. of Rated Capacity.
Maximum Load......................55 per cent. of Rated Capacity.
Average Load......................78 per cent. of Maximum Load.
Shafting..........................65 per cent. of Average Load.

No. 5.

imum or motor capacity system" of charges have adopted a schedule with the fact in view that where the motor is used for the usual run of intermittent work its average use is much below its capacity. The circumstances of motor use are, however, so varied that a system of rates or charges for power which shall better adapt itself to this wide range of conditions has already been adopted by many central stations, especially those operating constant potential power circuits. This system of charges I will call the "maximum reading system," which is based on the maximum reading of an amperemeter in series with the motor. The station supplying the power reserves the right in its contract with the customer to change or modify the charge for power from time to time as any increase is shown by these readings.

To illustrate more clearly this "maximum reading system" I would refer to diagram No. 23, which is a fair average record. This represents the record of a 15 h. p. motor operating lithograph presses, etc., the maximum reading in this case being 75 amperes, or, approximately, 10 h. p. The user is given a 10 h. p. rate,

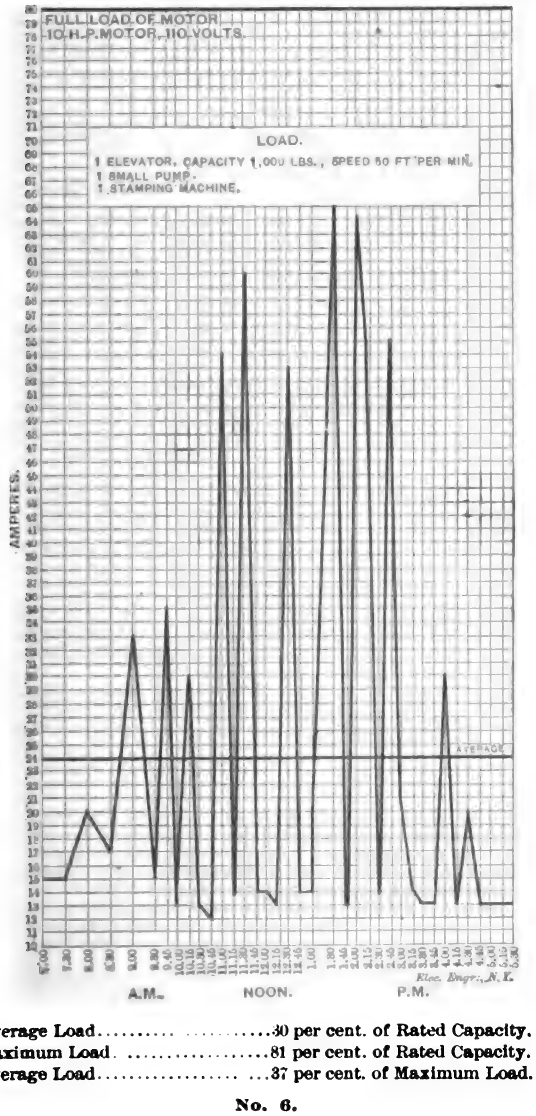
1. A paper read before the National Electric Light Association, Cape May, N. J., August 20, 1890.

which in this case happens to be $60 per month, or a rate of $6 per month per h. p. based on maximum readings. As the average power delivered to this user is but 67% of the maximum reading, the station actually receives at this nominal rate of $6 per h. p. an actual rate of $9 per month per h. p. for the power actually delivered.

The central station supplying this particular motor has adopted the "maximum reading system," and this rate of $6 per month per h. p. is their standard charge for motors showing a reading of 5 h. p. and over up to 15 h. p. From 15 h. p. up their charge is $5 per month per h. p. Their monthly bills are also subject to a discount of 5%, I believe, if paid promptly on the first of each month.

To return again to the diagrams. The records, twenty-nine in number, are of so varied a character that an average taken from all the records, will, I think, show within 1% or 2% of the general average conditions found in electric motor practice. The conditions as shown by these records are as follows:

Average load on motor, 43.57% of its capacity.
Maximum load on motor, 68.24% of its capacity.
Average load on motor, 64% of maximum load.



Average Load.............................30 per cent. of Rated Capacity.
Maximum Load............................81 per cent. of Rated Capacity.
Average Load.............................37 per cent. of Maximum Load.

No. 6.

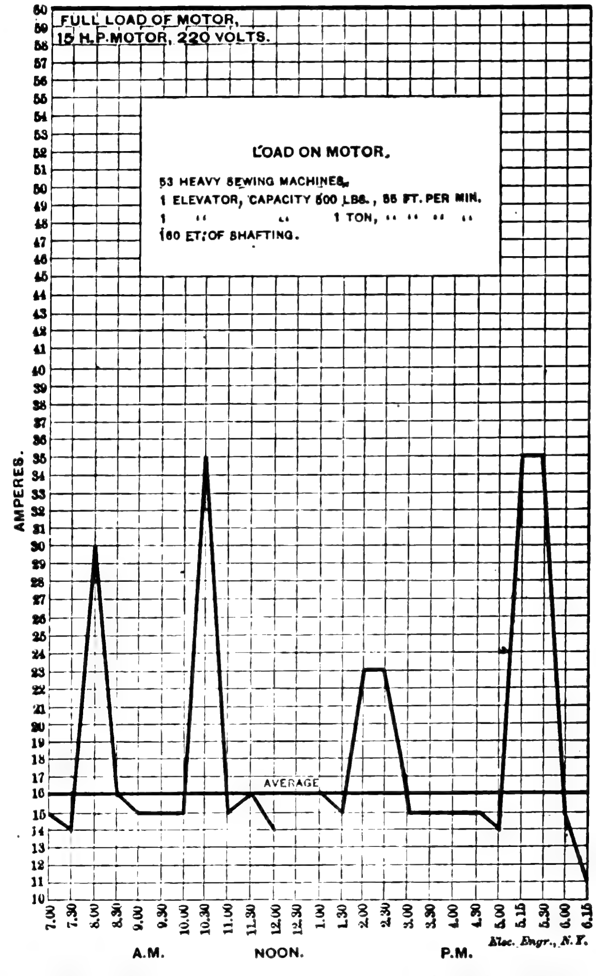
Reducing these averages to dollars and cents we have the following results:

A "maximum capacity" rate of $6 per month per h. p. pays the station $13.80 per month per h. p. for the power actually delivered. A "maximum reading" rate of $6 per month per h. p. pays the station $9.37 per month per h. p. for the power actually delivered.

$13.80 per month per h. p. is certainly a tempting price for power, but it is open to some serious objections. In the first place, at this price the electric motor, even with its much higher efficiency, cannot compete with the gas engine. A good gas engine uses about 20 feet of gas per hour per h. p., or about 5,200 cubic feet per month. Giving gas at $1.50 per thousand (and in many places it is much lower than this), the gas engine will deliver power at a cost of $7.80 per month per h. p. We can, without much trouble, obtain the $9.37 rate per month for a motor in competition with the gas engine, on account of its many and obvious advantages, but we can seldom obtain the $13.80 rate. This maximum capacity rate also very much hampers the user in a selection of a motor, and the motor salesman, in order surely to effect a sale, is very apt to underate the prospective load on the motor, as the customer is governed in his purchase of a machine much more by the monthly charge than by the first cost of the motor.

Another feature which must not be lost sight of is the fact that a motor user who has bought and paid for his machine becomes your permanent customer, his income being entirely derived from the product of the work of his motor. His bills for power you are also sure of collecting, for the moment his power is shut off his earning capacity ceases. The motor becomes to him an absolute necessity instead of a seasonable luxury, as is the case with many electric lights.

Another very remarkable feature brought out by these diagrams is the fact that the average power consumed in doing serviceable work is but three-eighths of the total power used, and the remaining five-eighths (68%) is consumed in driving shafting. This enormous loss in shafting would indicate that the day may not be far distant when each machine will be equipped with its



Average Load.............................26 per cent. of Rated Capacity.

Average Load.............................46 per cent. of Maximum Load.
Shafting.....................................71 per cent. of Average Load.

No. 7.

own direct-geared motor and that the days of shafting and belting are numbered.

As a concluding reference to these diagrams, let me call your attention to diagram No. 3, in which a condition presents itself with which you are familiar in theory, but which has, I believe, never before been practically illustrated, namely, the counter E. M.F. in the armature of a shunt wound motor driving a spur gear elevator. When the elevator is coming down with a load the counter E.M.F. runs above the E.M.F. of the supplying circuit, and therefore the motor becomes a producer instead of a consumer, and thus acts as a brake to retard the too rapid descent of the elevator.

Diagram No. 3 represents the record of a 7½ h. p. motor in a wine merchant's store operating an elevator, a small piston water pump and wine pump. The water pump is in continuous operation, the wine pump and elevator being only used intermittently. The current consumed in the shafting and water pump, which

constitute the continuous load, is 14 amperes. The difference between this 14 amperes and the several readings below that amount, shows the amount of current generated by the motor when the elevator is coming down. As this class of elevator is largely used, this peculiar fact becomes an item of considerable importance to the central station, and is also a strong argument in favor of a constant potential power circuit, as only on this circuit can these conditions be obtained.

I had hoped to prepare some diagrams of motors on series or arc light circuits for comparison with the records here submitted, and thereby illustrate graphically the advantages of the constant potential circuit for power distribution. Want of time has, however, prevented this.

In conclusion, let me read you some extracts from a letter received in March last from a prominent manufacturing corporation using 75 or 80 h. p. in motors in their work shops:

"We are running with one motor a large 4-ton Graves' elevator, and several wood-working machines, such as planers, cross-cut saws, etc. In our machine department, the several motors run several lines of shafting, independent of each other. In this department we run heavy planers, lathes, drill presses, shapers, slotters, gear-cutters and other machinery necessary to a complete machine shop. A motor in our department for fine wood work furnishes power for the various machines necessary to the manufacture of articles needing turning lathes, gig-saws, rip-saws, etc.

"In our experimental department and show room, we use a smaller motor, set with the necessary speed reducing pulleys and belts upon a movable frame. This we roll from place to place as convenience dictates. All of these motors are giving us unquali-

fied satisfaction, and we would not willingly return to direct steam engine power."

This company is being supplied with power by the local electric light company, on a basis of $50 per year per h. p. based on maximum readings. The user is apparently delighted with his service and perfectly satisfied with the cost of his power, and I have the assurance of the electric light company supplying the power, that they would be glad to load their plant under the same terms given this customer.

STANDARDS OF ECONOMY IN THE GENERATION OF POWER.[1]

BY H. M. SWETLAND.

In suggesting to our secretary the subject for this paper as one which would be of vital interest to the members of this Association, I had no idea that I should be called upon to prepare and present it, nor do I feel the fitness of my being chosen to instruct the gentlemen of the convention, whose knowledge upon these matters is the epitome of the best and highest accomplishment of the times.

The above title scarcely represents my treatment of the subject. I should prefer rather to call it "A plea for the collection and record of data for standards of economy." In old and long-established lines of work such would naturally be unnecessary. In the electric light business where so much is new, and development is so constant and rapid, it is essential that there should be established some authentic form of comparison of operations with the view of reaching the greatest economy in the shortest possible space of time. Further, in view of the rapidly changing conditions under which the generation of steam power is being operated, the concentration of small and individual plants into larger centres, etc., it becomes of the utmost importance that a careful and detailed system of standards shall be inaugurated and maintained.

Although far more able representatives than myself have heretofore approached this topic, there has been in the convention a noticeable lack of definite, reliable, incontrovertible information in this special direction.

The subject of economy in general has received the attention of our best thought, but it has been directed to the operations of the complete system, and too often details of definite expense are overlooked by the superintendent, whose imperative duty is the running of the plant, not its most economical methods. He is obliged to keep a station in smooth running order to furnish good steady reliable lights, under pressure of constant demand, in which case economy is not the first consideration.

At the last convention the admirable paper read by Mr. T. Carpenter Smith, of Philadelphia, entitled "A System of Central Station Accounts," touched upon and almost comprehended this necessity, but he still further included the maintenance of outside equipment, whereas my paper is confined to the question of first cost of production of power expressed in pounds of fuel per developed h. p. per hour.

The material for the data in furnishing standards of economy should naturally be the practical results of actual operations compiled in tables from the results obtained by different managers. To what end? They would interest and benefit all desirous of investing in electric light and power enterprises which are becoming such an attractive feature in the financial world. They would be useful to prevent the establishment of unnecessary and injurious

1. A paper read before the National Electric Light Association, Cape May, August 20, 1890.

competition frequently induced by statements of facts and figures showing an utterly false and unattainable economy.

But to the superintendent of the station, more than any other person, these tables would be of paramount importance. They would enable him at a glance to learn what others are actually accomplishing under certain named conditions, and readily to institute comparisons with his own records. By their use he would not only gain enlightenment on many points, but be stimulated to the highest possible degree of efficiency and economy. He would also thus be furnished with unimpeachable authority to offer a doubting stockholder or too exacting president, who, while perhaps not being initiated in the details of practical workings, is always glad to be reassured by accurate information.

These tables would not, however, be found elastic enough to suit the purpose of the energetic boomer whose object in building a station is sale, not operation, for they will be found to show the necessity of the best modern appliances to the most economical

No. 16.

production of power. Neither would they be particularly interesting reading to men who trade in inferior appliances.

A "standard of economy" is obtainable only by a combination of mechanism best adapted to the conditions and attendance which can secure from this mechanism the best possible results. A plant may be equipped with the most improved devices, the excellence of which may be practically nullified by neglect of well-known duties, ignorance or mismanagement. A poor gun in the hands of a good soldier is a better combination than a good gun in the hands of a poor soldier. It is not the machine alone, but combined with the skillful man behind it, that works out the best results.

This point was splendidly taken by Mr. George H. Babcock in his most valuable paper on "Boiler Economy," read before us in Kansas City. We all remember his allusion to "boilers and brains," or the "co-efficient of common sense."

It is perhaps superfluous to mention that results obtained with different existing equipment and attendance vary fully as 1 to 5, with a possibility of the still further lowering of the former proportion by investment in still better equipment constructed by still greater skill managed and operated throughout by superior intelligence, and yet these proportions, which to-day show such wide results in fuel consumption, may, by the combination of intelligence, energy and care, be made to show results more nearly proportioned to the possibilities of the present equipment by placing on record the best results obtained from a similar system.

Of course no absolute standard or unit of economy can be established by a vote of convention or fiat of association. A yard stick is a yard stick, an inch an inch, but a standard of economy must always vary in greater or less degree, according to conditions and equipment. Yet a sufficient similarity exists to enable us

to prepare tables covering the main types of equipment, and the recorded performance of any special type would be relied upon and regarded as a standard. Human ingenuity, talent, patience, skill and incessant labor are being exerted every day and hour in the direction of lowering the records. The ambition of the day is turned towards producing the maximum of result with the minimum of expenditure. Standing in comparison with the fifteen minutes of the ocean racer, the second clipped from the tables of the turf, or the extra grain made to yield from the refractory ore,

is the ounce of fuel measured in the economic generation of power when considered on the large and increasing scale of commercial enterprise.

My plea is for the most minute and detailed system of tabulation as the means of reaching the best results. It is by the comparison of coal with coal, boiler with boiler, engine with engine, type with type, appliance with appliance, that these results may be obtained. Those who have had experience in collecting data of the kind required will comprehend at once the difficulties encountered in the process of getting information which shall fully cover the many important points in the case. Not only should there be no objection on the part of the companies, their managers or superintendents, to giving information that is reliable in

Shafting..............................70 per cent. of Average Load.

No. 25.

character, accurate in detail, and comprehensive in scope, but there ought to be most cheerful acquiescence.

We are organized for purposes of free interchange of thought and experience, with a view to mutual advancement and benefit. In these tables each one is liable to discover information upon some important point which should be of great value to him. Naturally the broad ground of justice, fairness and liberality of feeling is expected to be our starting point.

If I have succeeded in interesting the gentlemen in the importance of "collecting data for these standards," I will feel justified in having consumed the time of the convention. If carried out we will reap the benefit in having on record the facts and figures which have been so often called for; and the answer to the three great questions :—What is your equipment? How many lights do you furnish? How much coal do you burn?

TRIPLE EXPANSION HIGH SPEED ENGINES FOR CENTRAL STATION WORK.[1]

BY E. F. WILLIAMS.

I HAD hoped to get enough accurate data concerning the performance of triple engines to bring before you and to make the subject the basis of a paper, but circumstances have been such that the engine I attempted experimenting on has been so situated that I could not get it rigged up for making the tests, and therefore I cannot give you any accurate data in regard to high speed triple expansion engines for central station work. The main points to be considered in the matter are, however, first, the matter of regulation. Perhaps that is of the highest importance and the matter that is in most question by engineers as to whether there will be a momentary variation in the speed of the triple engines when the load is suddenly increased or decreased that would not occur in single cylinder engine practice. Now that matter depends mainly on the weight of wheel and the intermediate spaces or clearances, and will be modified more or less by the accuracy or quickness of the governor; and as to whether this can be done or not, I will say yes, it can be done. The weight of wheel can be made sufficient, the clearances can be made sufficiently small and the governor can be made sufficiently quick, and it is done so that the engine will not vary materially under sudden changes of load. Of course the smaller the clearances the heavier the wheel, and the quicker the governor the less will be the momentary variation. As to the matter of cost, taking the entire plant considered as a whole, boilers, engines and all, the triple will cost, I presume, approximately 20 per cent. more than the compound. The economy of triple is unquestionably considerably in excess of the compound on the evidences so far taken from marine practice, for example, about 20 per cent. in the compound. It is a fact that compound plants under ordinary circumstances where coal is, say, at an average price of $3 per ton, will consume their entire first cost in about five years' work in coal bills. Assuming that the triple will save 20 per cent. over the compound, the triple would save the excess of cost over the compound in the first year's service.

There is another matter to be considered, namely, the reliability of the machine and the smoothness of action. The triple has advantages over the compound in that respect, theoretically, which, as far as we know of it, practice has sustained. It appears that the triple engine is a much easier engine to care for than the compound. The compound is much easier to care for, ordinarily, than the single, for reasons which are accounted for in theory, and I think the practice will sustain the theory.

1. Delivered before the N. E. L. A., Cape May, Aug. 21.

TWELFTH CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION, HELD AT CAPE MAY, NEW JERSEY.

TUESDAY, AUG. 19, 1890.—MORNING SESSION.

The Association met at the Stockton House, Tuesday, August 19th, 1890, and was called to order by President Perry at 10.30 A. M.

The following members and visitors were present at the convention:

ALLEGHENY, PA.—A. Groetzinger.

ANSONIA, CONN.—F. B. Platt.

ATLANTA, GA.—John S. Alfred.

BOSTON, MASS.—P. H. Alexander, G. L. Austen, F. E. Barker, S. E. Barton, Capt. Wm. Brophy, A. N. Burbank, Louis W. Burnham, C. L. Edgar, F. E. Cabot, Wm. W. Castle, H. J. Conant, H. E. Duncan, H. H. Eustis, H. M. French, A. V. Garratt, C. M. Goddard, L. H. Hart, J. R. Lovejoy, A. F. Mason, E. C. North, F. E. Pettingell, R. F. Ross, A. C. Shaw, R. T. White.

BRIDGEPORT, CONN.—W. C. Bryant, J. M. Orford, O. S. Platt, H. D. Stanley.

BRISTOL, PA.—Chas. E. Scott.

BROOKLYN, N. Y.—E. F. Peck.

BUFFALO, N. Y.—C. Lee Abell, C. R. Huntley, W. H. McDonald.

CHICAGO, ILL.—W. P. Adams, J. P. Barrett, John W. Blaisdell, Chas. A. Brown, E. V. Cavell, Geo. Cutter, J. W. Dickerson, Fred. Degenhardt, Henry C. Eddy, C. E. Gregory, W. A. Kreidler, Geo. A. McKinlock, E. L. Powers, J. W. Shay, J. H. Shay, H. H. Small, Gilbert M. Smith, Ed. F. Williams, C. H. Wilmerding, H. S. Winston, F. A. Wunder, John Young.

CAMDEN, N. J.—Hon. E. A. Armstrong, J. J. Burleigh, C. L. Rodman, Heber C. Robinson.

CINCINNATI, O.—James Powell.

CLEVELAND, O.—C. C. Curtis, W. B. Cleveland, J. B. Crouse, Benj. F. Miles.

COLORADO SPRINGS, COL.—E. C. Wade.

DALLAS, TEX.—W. M. Clower, C. O Harris.

DETROIT, MICH.—Jesse M. Smith, Fred. Whipple.

ELGIN, ILL.—G. S. Bowen.

FITCHBURGH, MASS.—H. F. Coggshell.

FLINT, MICH.—A. G. Bishop.

FT. WAYNE, IND.—W. R. Kimball, M. M. M. Slattery.

HARTFORD, CONN.—W. G. Halm, C. L. Tolles, Francis P. Whiting.

KANSAS CITY, MO.—M. E. Bates, G. W. Hart, Geo. H. Hegeman, E. R. Weeks.

MONTREAL, QUE.—A. J. Corriveau.

NEWARK, N. J.—C. O. Baker, Jr.

NEW BEDFORD, MASS.—Chas. R. Pine, Mr. Underwood.

NEW BRITAIN, CONN.—T. H. Brady, L. C. Whitney.

NEW ORLEANS, LA.—S. J. Hart.

NEW HAVEN, CONN.—J. English, C. D. Warner.

NEW YORK.—P. C. Ackerman, F. M. Adams, E. P. Atkinson, C. H. Barney, Wm. Bracken, L. D. Beck, Louis Bell, Edward Caldwell, W. L. Candee, Stephen L. Coles, Francis B. Crocker, W. F. Cullen, C. J. Field, G. H. Fisher, W. H. Fleming, A. R. Foote, R. E. Gallaher, E. T. Greenfield, J. W. Godfrey, R. J. Gray, W. H. Gordon, Wm. J. Hammer, Geo. H. Hartwell, H. M. Haines, W. J. Jenks, E. H. Johnson, W. J. Johnston, Jas. F. Kelly, Theo. Larbig, A. B. Laurence, H. Ward Leonard, E. W. Little, H. L. Lufkin, O. E. Madden, J. P. McQuade, Frank A. Magee, Geo. T. Manson, T. C. Martin, Geo. H. Meeker, T. McCoubray, W. J. Morrison, E. Myerson, Geo. M. Phelps, Chas. A. Place, Geo. B. Prescott, Jr., C. W. Price, R. W. Ryan, J. R. Stagg, John A. Seely, L. W. Serrell, Ralph L. Shainwald, H. L. Shippey, C. W. Spear, C. E. Stump, H. M. Swetland, J. B. Taltavall, Robert Taber, Wm. H. Temple, J. Van Gestel, C. S. Van Nuis, F. Warder, Jean A. Wetmore, Benj. R. Western, Jos. Wetzler, S. S. Wheeler, G. L. Wiley, Harry W. Williams, E. E. Wood, E. P. Wisner and C. G. Young.

NORTHEAST, PA.—A. L. Daniels.

ORANGE, N. J.—Chas. Wirt.

PHILADELPHIA.—Henry N. Almy, C. A. Bragg, David Brooks,

H. A. Cleverly, D. O. Conner, W. A. Drysdale, A. J. De Camp, F. H. Deacon, W. R. Hood, Norman Marshall, W. McDevitt, W. C. McIntire, Alfred F. Moore, H. G. Morris, Geo. F. Porter, O. D. Pierce, H. S. Smith, T. C. Smith, W. A. Stadleman, W. H. Shoemaker, G. A. Wilbur, Elmer G. Willyoung.

PITTSBURGH, PA.—H. L. Angloch, S. A. Duncan, A. E. Carrier, J. W. Marsh, Morris W. Mead.

PLANTSVILLE, CONN.—H. C. Roberts.

POTTSTOWN, PA.—Chas. E. White.

PORT HURON, MICH.—W. F. Davidson.

PROVIDENCE, R. I.—Marsden J. Perry, Geo. H. Wood.

RUTLAND, VT.—M. J. Francisco.

SAN FRANCISCO, CAL.—Geo. H. Roe.

ST. LOUIS, MO.—Robert McMath, C. C. Moffitt, Russell Parker, D. R. Russell.

TOLEDO, O.—C. R. Faben.

TRENTON, N. J.—F. A. C. Perrine.

WATERBURY, CONN.—A. M. Young.

WILMINGTON, DEL.—H. B. Cobb.

WINDSOR, CONN.—M. E. Baird, A. D. Newton.

WASHINGTON, D. C.—F. W. Royce, A. M. Renshaw.

WORCESTER, MASS.—H. M. Smith.

The ladies attending the convention were as follows:

Mrs. G. L. Austen, Mrs. P. H. Alexander, Miss E. W. Armstrong, Mrs. C. O. Baker, Mrs. C. H. Barney, Mrs. Chas. A. Bragg, Miss Myrtis Barton, Mrs. S. E. Barton, Mrs. J. J. Burleigh and daughter, Mrs. J. P. Barrett, Mrs. W. L. Candee, Mrs. Wm. M. Castle, Mrs. Geo. Cutter, Mrs. A. J. De Camp, Mrs. C. R. Faben, Miss M. B. Ford, Mrs. M. J. Francisco, Mrs. R. E. Gallaher, Mrs. G. W. Hart, Mrs. Harris, Mrs. E. H. Johnson, Mrs. W. J. Johnston, Mrs. Jas. F. Kelly and child, Mrs. W. R. Kimball, Mrs. E. W. Little, Mrs. Geo. T. Manson, Mrs. A. F. Mason, Miss Kate Mitchell, Mrs. W. C. McIntire, Mrs. J. P. McQuade, Mrs. J. M, Orford, Mrs. F. E. Pettingell and Master Roger Pettingell, Mrs. G. B. Prescott, Jr., Miss Ridlon, Mrs. John A. Seely, Mrs. M. M. M. Slattery, Mrs. W. A. Stadleman, Mrs. C. D. Warner, Mrs. E. R. Weeks and child, Mrs. Schuyler S. Wheeler, Mrs. Fred Whipple, Mrs. Geo. H. Wood, Mrs. John Young, Mrs. Lenox and Miss Lenox.

The president read the following address:—

PRESIDENT PERRY'S ADDRESS.

You are here to-day to erect, by mutual action, another milestone—in the form of the volume that will be created to contain a record of your proceedings—to mark the progress of the development of the electrical industries. Short as the history of this development is, it has been so crowded and broadened by the eager enterprise that is characteristic of our people, that no records are to-day sufficiently ample and complete to give any of us a correct knowledge of the present condition of the multitude of undertakings employing electricity in some form of practical application.

To supply this deficiency a "Memorial and Statement" has been presented to Congress in the name of this association, urging that the fullest possible investigation and report be made on the electrical industries by the eleventh census. This association can do no more important work for the interests it represents than to select from the census reports certain points of inquiry, and adopt measures to keep them continuously written up to date. Recommendations looking to this end may be presented by the committee on data.

As a general statement it may be assumed that there is to-day a central lighting and power station in operation in every town of any importance in the United States. An estimate made by, and published in, the August number of *Electrical Industries* makes the following showing:—

Number of stations	1,379
Capital invested	$118,758,500
Number of arc lights	127,441
Number of incandescent lights	1,590,967
Engine capacity, h. p.	356,755

Eloquent as these figures are of enterprise and progress, they tell but part of the story. One startling omission is that of the electrical transmission of power for stationary and locomotive work. The statements, however, may serve the purpose of helping the imagination to picture the results that are to be shown by the census of the century in the year 1900.

It is a safe assertion that there is not a station in this country with a present capacity sufficient to satisfy one-twentieth of the demand for light and power, that exists within the area of its practical working limits. To reach the consummation of ultimately doing the entire lighting and power service that is to-day being supplied by the use of agents other than electricity, is an undertaking worthy of the united efforts of all who are interested in the electrical industry. The foundation for such a growth must be laid in an unquestioned demonstration that investments in central stations for supplying light and power by the use of electrical currents, are safe and profitable, that the service is—in comparison with that rendered by other agents used for similar purposes—a protection to life and property, and that the service can be employed with advantages in economy, health and comfort, by all users that cannot be realized by the use of any other agent.

Those who know best what is required to meet all issues and to establish a business involving the complex factors and conditions assembled in undertakings for central station work, are those who have invested their money in it and are employed daily in its management. To them and their interests, which includes that of all who manufacture apparatus and supplies, as surely as the greater comprehends the lesser, this Association is pledged for well-considered and effective work.

In your deliberations and discussions you have an opportunity to show your thorough knowledge of the subjects in which you are interested. By your actions you can prove yourselves masters of the factors that induce progress and invariably lead to successful issues.

The Twelfth Convention of the National Electric Light Association is now open for the consideration of such subjects and business as may come before it.

The secretary read the following announcement of the order of business:

For the purpose of securing orderly and prompt action for those attending the Twelfth Convention, the Executive Committee has appointed a Committee on Credentials, the members of which are:

Edwin R. Weeks, Chairman; M. J. Francisco and John A. Seely. The committee recommends the appointment of a Committee on Resolutions to consist of three members. The Executive Committee believes that many questions that can be discussed with great profit to members of this Association do not come to the surface in set papers, nor in the reports of committees. That every such question may be considered a call for "Topics to be Discussed," will be made at each session except the last. All topics so proposed will be referred to the Committee on Resolutions, and, if approved, a place will be found for the topic in the order of business.

MR. FABEN, of Toledo, moved that the recommendation read by the secretary be approved, and that the chair appoint a committee of three on resolutions. The motion was carried and the president appointed as such committee Messrs. A. F. Mason, C. H. Wilmerding and C. R. Huntley.

The paper by Prof. J. P. BARRETT, of Chicago,[1] was then read by Mr. Blaisdell, and was discussed as follows:

MR. FABEN—There certainly will be no one enterprise presented at the World's Fair that will interest central station men as much as will the electrical department. The amount of detail required to develop a proper exhibition of the appliances presented there, and to induce manufacturers to present those features of their business that will be not only of interest to themselves but to central station people as well, and the amount of work involved in the undertaking, demands that action should be taken by this Association now. This being a central station association, the central station people ought to go to work very promptly to lay plans for securing a proper exhibition at that time. For that purpose I would like to present a motion as follows:

That a committee of five be appointed, of which number the president of the association shall be ex-officio one, the other four members to be appointed by the chair, to meet the authorities of the Columbian Exposition and secure suitable facilities for the proper exposition of electrical manufactures and appliances, and, in general, to work for the interests here represented, and to offer to the authorities of the exposition the co-operation of the National Electric Light Association to aid in making the exposition a success.

That the committee request the selection by the authorities of the Columbian Exposition, of Mr. John P. Barrett, of Chicago, to have the practical charge and control of the electrical department of the World's Columbian Exhibition.

MR. G. M. PHELPS, of New York—I have great pleasure in seconding the resolution which Mr. Faben has offered and both features of it: That is, the appointment of a committee to secure suitable facilities, and tendering the co-operation of this body with the authorities of the Fair, and also recommending the appointment of Mr. John P. Barrett. The paper which has been read to us this morning is about as good evidence as we might need, perhaps, of the fitness of Mr. Barrett for that work, although doubtless most of us knew that well enough before. A further reason is that Mr. Barrett has already been commended to the World's Fair Commissioners by the signatures of very many of the most prominent electrical people, electricians, electrical engineers, manufacturers and users of light and power. I think that it would be eminently fit and proper for this Association to take such action at this time as has been proposed. The sooner such action can be had the better it will be for the exhibition. I presume that there is no doubt in the mind of any member of this Association of the entire fitness of Mr. Barrett for the position. I therefore second the motion.

MR. ARMSTRONG, of New Jersey—I am most heartily in favor of all of the resolution except that part of it which recommends the appointment of some particular individual. I think that this

1. See page 207.

Association would make a serious mistake if it did that thing. I have myself recommended the appointment of Prof. Barrett, and personally I am heartily in favor of his appointment, and personally am willing to do everything possible to secure that appointment; but it seems to me that the Association would be making a serious mistake if it lent itself to a recommendation of any individual for any appointment. (Applause.) I should be very sorry to see this Association join in recommending anything where there is a possibility of there being, with merit, some competition against it; and I believe that every member of the Association would join with me in deprecating the recommendation of anything, no matter how good it might be, if, with merit, some competition could be brought against it. We want to be in the position, beyond any question or any cavil, of disinterestedly and impartially standing here as representing all and everything connected with the industry with which we are associated. We do not want to have the slightest possible suspicion that we are biased in any direction. Therefore, I am very glad to vote for this resolution if we may have that part of it omitted. I may say to the gentlemen who have moved and seconded the resolution that I am willing to join with them, individually, in doing everything possible to have the gentleman who has presented such an interesting paper to us appointed to the position they desire to see him appointed to; but do not let this Association adopt such a resolution. It would be weakening to us, and I think it would be weakening to him. (Applause.)

MR. P. H. ALEXANDER, of New York—This morning I received a copy of the electrical journal of the West, *The Western Electrician*, and its first editorial speaks about mistakes having been made by the Association here at a former meeting at which the Association voted to have the World's Fair held in New York instead of in Chicago (Laughter); and especially recommends that we take no action whatever, and do not commit ourselves further in any way whatever, without first having due deliberation. Now the resolution offered by Mr. Faben, and seconded by Mr. Phelps, coming immediately after the paper by Prof. Barrett was read, puts Prof. Barrett himself in rather a delicate position. His paper speaks particularly of the advantages that could be derived by the proper arrangement of electrical exhibits at the Chicago Exhibition; and I do not think that he himself would like the resolution to come up now, at least not in that form. If notice had been given by these gentlemen that such a resolution would be brought up in the course of the session it would have given opportunity to gentlemen who are interested in the subject to confer with each other regarding a proper appointment. I therefore move that that resolution be tabled.

MR. F. E. DEGENHARDT, of Chicago—I would be untrue to the city of Chicago, and to my friend Prof. Barrett, if I did not raise my voice in support of his appointment. As I understand it, the resolution has for its object the successful operation of the World's Fair. In the appointment of a neutral man like Prof. Barrett, we have in him all the qualifications set forth in the resolution; and I would like to add that the very support which has been granted to him by signatures throughout the United States is a sufficient guarantee of the feeling which must exist. Of course we Westerners recognize the fact that you are dying very hard back here, and the World's Fair seems to be the red flag that excites the bull, so to speak. Prof. Barrett is known throughout the United States as an absolutely neutral man. I I think that he is free and untramelled. He has no affiliations that we know of, and is therefore a man qualified for the position. I think that this Association owes the city of Chicago as a debt the adoption of this resolution.

MR. S. A. DUNCAN, of Pittsburgh—As a substitute for the pending motion I move to refer these resolutions to the committee already appointed by the chair.

After some debate by Messrs. De Camp, Alexander, Armstrong and Brown, the motion was carried and the resolution referred to the Committee on Resolutions.

THE PRESIDENT—The next order of business is the report of the Committee on Copper Tariff, by Mr. Charles A. Brown, of Chicago.

REPORT OF COMMITTEE ON COPPER TARIFF.

MR. C. A. BROWN, of Chicago—We had expected that by this time Congress would have passed a tariff bill, and that thus there would be some definite result with reference to the duty on copper, in securing which the committee could claim some part. But you all know what the present situation regarding the tariff bill is. The original bill introduced by the Committee on Ways and Means provided for a reduction of fifty per cent. of the duty on various forms of copper. This provision of the bill as introduced into the House was not changed in the House. In the Senate the clause relating to the duty on copper was amended by further reducing the duty to one-half cent per pound on ores and one and one-quarter cents per pound on ingots, bars, plates, and pigs, being a reduction of seventy per cent. in one case and eighty per cent. in the other from the present schedule of duties. It is reasonably sure that if the Tariff Bill becomes a law at the present session of Congress the duty on copper will be reduced at least fifty per cent. Your committee has secured something over five hundred signatures to a petition addressed to the Committee on Ways and Means requesting the abolition of the duty on copper. We have mailed something over a thousand circular letters, and have made in addition to that a good many personal solicitations. Mr. Phelps, of the committee, personally went to Washington with the signatures to this petition and presented them to the Committee on Ways and Means, with a brief but forcible argument in favor of the petition. As no appropriation was made by the Association to meet these expenses, the members of the committee themselves advanced the necessary money for postage, traveling expenses, express, etc., to the amount of $110, in carrying out what seemed to them to be the spirit of the instruction contained in the resolution on appointing this committee.

MR. A. J. DECAMP moved that the report be accepted and the committee continued. The motion was carried.

MR. P. H. ALEXANDER—Moved that the treasurer be instructed to reimburse the committee for its outlays of $110. This was carried.

MR. DECAMP—I want to give notice of my intention to offer a resolution to reconsider the action taken by the Committee on Resolutions. My reason for offering that is this: While the plan proposed is a most admirable way of presenting the business for a body that has unlimited time to discuss and get through with its business, I think if that resolution prevails that we will do very little business in the three days in which we meet to transact our business. I think it is too cumbersome for this association.

THE PRESIDENT—I wish to announce that the following topic has been proposed for discussion: "The Proper Classification of the Lighting Power of Incandescent Lamps." Dr. Louis Bell, editor of *The Electrical World*, will open the question. The announcement is made in advance, so that all who desire may have an opportunity to be present and take part in the discussion. I think it is important.

The Association then adjourned until 4 p. m.

TUESDAY AFTERNOON SESSION.

Called to order at 4 P. M.

The President opened the session by reading a telegram from Mr. M. D. Law, of Denver, Col., wishing success to the convention and regretting his inability to be present.

THE PRESIDENT—The first thing on the opening of this session will be a five minutes' talk by Mr. David Brooks, of Philadelphia, on

THE USE OF LIQUID INSULATION FOR UNDERGROUND CONDUCTORS.

Since electric lighting came into use it has been found that the ordinary tests for insulation do not apply; that is, a test with a galvanometer and a voltaic battery of, say, 1 to 500 cells. That has become apparent, and they have adopted other means in Paris and in London for testing the insulation of conductors that have to carry very high intensity currents. We have seen this noticed in many periodicals. Mr. William Maver, Jr., in a recent article states that a cable measuring 20,000 megohms per mile, for insulation in the factory, broke down by a dynamo current of 600 volts after being drawn into a conduit. Now in the ordinary test, if a person should go and measure the insulation of an electric light cable and he found that it was 20,000 megohms per mile, and he took another system of insulation and found that it was only half a megohm per mile, as a general result he would take that which stood 20,000 megohms to a mile; but if you apply to it a current of high voltage from an induction coil or a Holtz machine, you can prove that the one with the 20,000 megohm insulation per mile was broken down by from 5 to 10,000 volts. Now you take the same No. 4 conductor and insulate it in oil for 20 feet, just as an experiment, and raise the temperature to 200 Fahrenheit and apply the galvanometer, and it is not a half a megohm per mile—just about the one-fortieth part of the one that Mr. Maver speaks of; but when you come to apply the induction coil or the Holtz machine and test it to produce what is sometimes called the break-down or a disruption, it can be broken with 10,000 volts when the other can not be broken with 500,000 volts. There is the difference between the testing of the insulation of a cable, or an insulator, or a dielectric, if you please, by testing it with the ordinary delicate galvanometer, static galvanometer, and testing it for standing a current of high voltage. Now if the current applied to a conductor tests half a megohm per mile, the temperature of the insulation being 212 Fahrenheit, that would not show much; no one on first sight would buy it; but if you are going to purchase a cable and test it as they do in England, or give the guarantee as they do now in England, there would be five parts of current going through the insulation, to 500,000 parts going through the conductor; and the small proportion that goes through the insulation is a mere bagatelle, but it stands the current. These are experiments that I have made in Philadelphia and I would do it here with a Holtz machine, but the atmosphere in the summer and especially on the sea shore is very unfavorable to the use of a Holtz machine. (Applause).

The paper on "Dangers from Electricity,"[1] by Prof. Henry Morton, of the Stevens Institute of Technology, Hoboken, New Jersey, was then read by Mr. Alexander.

1. See page 208.

In the discussion, Mr. W. R. Freethy, of the Employer's Liability Assur. Co., of Boston, remarked that it was the object of his company to bring about a better condition of things than exists at the present time in connection with the instructions to employés of electric light companies with regard to the dangers which surround them in carrying on their daily operations. When his company started in business here a few years ago they found that, in consequence of its being the first one to introduce what is known as employer's liability insurance in the United States, they had really no experience to guide them upon which they could found rates of premium for the various electrical risks. They therefore established what they considered to be a fairly reasonable rate to charge the electric lighting employers in order to protect them with regard to their legal liability for accidents to employés. But, in the course of a short time they found that the rate was inadequate. They found that several serious accidents occurred amongst their policy holders, and, what was of greater importance to them in carrying on their business, they found that the prejudice of the public, which was aroused by the press from time to time, whenever an accident occurred, made it impossible to carry that case before a jury.

The result was that they were compelled to increase their rates of premium by nearly 100 per cent. They then set themselves to try to find out whether they could do anything to bring about a better state of things, so as to reduce the rate of premium charged to electric light companies. They accordingly issued a circular to their policy holders, asking them to send them copies of their regulations for the guidance of employés in carrying on their work. All these regulations, and the matter generally, were submitted to Prof. Henry Morton, for his consideration. He drew up the set of regulations which are contained in the paper, and the company consider them very good.

In answer to a question from Mr. M. J. Francisco, Mr. Freethy said that the premium is based upon the wages or upon the payments. They charge one and one-half per cent.

Mr. Francisco characterized the action of the company in raising the rate, in face of the good showing of only 16 per cent., of accidents due to the current, as unjust to the electric light companies.

Mr. P. H. Alexander then offered the following resolution:

Resolved, That it is the sense of this Association that a copy of the rules prepared by Professor Morton, as embodied in the paper read before the meeting to-day, ought to be conspicuously posted in every electric light station.

The resolution was seconded and unanimously adopted.

Mr. E. A. Armstrong, of Camden, remarked that for over five years he had operated a station and had no accident of any kind, with but one single exception, namely that of a door of the boiler room which fell down on one of the employés and hurt him somewhat, but which would hardly be charged against the electric light station.

Mr. Armstrong then moved that the Committee on Data be requested to examine into and report all accidents happening in electric light stations, and to what they may be attributed. The motion was carried.

Mr. J. A. Seely, of New York, moved that a vote of thanks be extended to Professor Morton for his valuable paper and that the secretary be instructed to print the same in the proceedings. Carried.

Mr. Geo. Cutter, of Chicago, then presented the report of the Committee on National Insurance Rules.

REPORT OF INSURANCE COMMITTEE.

Your committee have at this session simply to report progress, as the object for which it considers itself appointed has not been completed, viz., the codification of a set of rules regarding electric light and power installations which shall become national in character, and be used instead of the many sets of rules put forth by the different insurance associations throughout the country.

We have written the following letter to many insurance associations throughout the United States:—

"*Dear Sir:* At the last meeting of the National Electric Light Association in Kansas City, a committee was appointed to select delegates or representatives from the different insurance associations in the country, and also from the electric light companies to a national electric insurance committee. This committee will probably consist of eleven or thirteen members, the majority to be insurance men. They are to devise a set of insurance rules concerning electric light installation which shall be enforced all over the country. It is found at present that different rules are in force now in the different parts of the country, and in many places two sets of rules, more or less conflicting, cover the same territory. We hope to remedy the evils of this by devising one set and have this set supported by insurance men throughout the United States.

"In order to have these rules the best for the purpose, they should represent the average opinion of the various men who have had experience in this particular line, and also who represent the different interests involved. It is our aim to get a committee thoroughly well balanced as to the conflicting interests, so that the resultant opinion of them all will be so strong an expression of the best methods for electric work as to meet the support of all the insurance people and the electric light people also.

"We wish you would name your choice as a representative upon this committee. We are already accumulating a great deal of information on insurance rules all over the world, so that when this committee hold their meeting they will have the work so far advanced that a good set of rules can be arranged without very much delay.

"As there are many electric light inspectors who have had valuable experience and understand the subject pretty well, whom we expect to have upon this committee, we feel that such committee will be a great benefit both to insurance and electric light interests. It is our ambition to have this committee so carefully selected that it will become a body of referees to settle all important questions arising in relation to proper electric work. We trust you will realize the importance of this, and give it prompt and careful attention, and be prepared to support the decision of such a committee.

"Hoping to hear from you soon, and to have your support in this valuable work, we remain, etc."

The answers to these letters were almost universally favorable, and contained many expressions of appreciation on the part of the insurance people of the efforts made by this association to work in harmony with them in devising these rules and in advancing information leading towards good and safe construction.

You can, of course, readily understand that it has occupied much time and correspondence to determine just what associations to approach, and how to approach them, and get them to fully understand our object, in order that they should send a representative to act upon this committee. As a result of this work we have the pleasure of informing you that the following gentlemen have come to Cape May as representatives of the various associations and companies named:

COMMITTEE ON NATIONAL INSURANCE RULES.

George Cutter, Chairman.

COMPANY.	REPRESENTATIVES.
Edison	W. J. Jenks.
Thomson-Houston	J. R. Lovejoy.
Westinghouse	P. H. Alexander.
Engineering Firms	T. Carpenter Smith.
Electrical Supplies	George Cutter.
Phila. Bd. of Fire Underwriters	Wm. McDevitt.
New York Bd. of Fire Underwriters	Wm. D. Boughton.
Underwriters Assoc. of Mid. Dept.	H. O. Kline.
Nat. Bd. of Fire Underwr's N. Y.	A. A. Anderson.
Asso. Factory Mutl. Ins. Co., Boston	Capt. Wm. Brophy.
Boston Bd. of Fire Underwriters	F. C. Cabot.
Western Union Fire Underwriters Association	C. E. Bliven.
Cleveland and Chicago Boards	John P. Barrett.
St. Louis Board	Robert H. McMath.
Central Station Insurance	S. E. Barton.
New England Insurance Exchange	C. M. Goddard.
Southeastern Tariff Association	John S. Alfred.
Underwriters Assoc. of N. Y. State	— Babcock.

These gentlemen have been in session most of the time for several days discussing the different rules, and laboring to outline a framework, so to speak, or what they term generic rules. It was the general feeling that these rules should be made concise, and as few as possible, and still cover the basic principles of good work.

Your committee have the pleasure of stating to you that the insurance representatives were quite generally agreed with a feeling of good-will towards electric light and power installations, and they do not feel afraid of them.

The deliberations upon these set of rules have been referred to a sub-committee for further study, both to eliminate any mistaken positions, and also to frame them in proper wording.

They have also taken the necessary steps to communicate with one another for the purpose of arranging these rules so they can meet the approval of the different representatives and be adopted in place of the rules now in force. It is the opinion of these gentlemen that this work will be accomplished, and that they will enable your committee to report to the next meeting of this Association the uniform set of rules that you have wished for, and also that they will be supported by the various insurance associations.

It was voted at the last meeting that we should express to you their appreciation of your efforts to work in harmony with them in this direction and assure you of their good-will and reciprocity of feeling in the same line.

Your committee have also corresponded with various European authorities to learn their methods of inspection, and also to secure copies of the rules they have in force, and we have in our possession various sets of rules from England, France, Germany, and Italy, and these sets of rules, with their accompanying information, will probably influence to a considerable extent the rules which we will adopt. The force of this can be especially appreciated by quoting part of the report of the committee on light-

ing, heating, and patents, appointed by the National Board of Fire Underwriters, which report was presented to the National Board last winter.

"The great problem before us to-day, however, is the management of the various systems of electric lighting so as to ensure safety from fire. When such lights were first introduced, underwriters congratulated themselves that at last the long sought means of illumination without danger had been found. No matches, no kerosene explosions, no swinging gas brackets would hereafter vex them, but a steady, safe and brilliant light, which could do no possible harm, had come among us and all were happy.

"It did not take many months, however, to discover that the electric light was not the harmless thing we had imagined, but that it was a most prolific source of danger, and its introduction has cost the insurance companies more than any method of lighting heretofore in use. It has come to stay, and sometime it will probably be as safe as any light in use, but our knowledge of its properties and of its management must be vastly increased before that time appears. We see the danger, but as yet are too ignorant to point out the remedy. What yesterday seemed a safe method of installation, to-day proves dangerous, and what we regard as safe to-day is likely to develop danger to-morrow. We can only wait and study.

"For a number of years the National Board has followed the action of the New York Board in the matter of rules of regulating electric light equipments. Those rules were revised and re-issued by that Board, Jan. 15, 1890, and it is recommended that they be adopted by this body as thus revised, and promulgated to members.

"In this connection, it is proper to say that the National Electric Light Association, in a letter appended to this report, asks the National Board to nominate a representative upon a committee to be drawn from bodies of underwriters, and electrical experts in different parts of the country, to devise and recommend rules for electric light installations, which shall be uniform throughout the land, and tend to throw safeguards about the use of such lights. Your committee recommends that the invitation be accepted, and a representative appointed. Certainly nothing but good can come out of the deliberations of such a committee, and it is necessary that we should in every way increase our knowledge of what has become so important a factor in our business, and if possible, remove some of the dangers now attending it.

"Precisely what is expected of this committee in regard to the third topic named in this report, viz., "Patents," they are unable to say, but nothing in this department has been brought before them which seems to require any report."

And then to show the opposite opinion held by insurance companies in Europe, as well as many in this country. The Phœnix Fire Office Rules of London were issued in 1882, and their edition of 1889 contains the following statements, viz: "Notwithstanding the number of years that these rules have been in force, not a single fire has yet occurred from any electric installation that has been placed up in compliance with them. The electric light is the safest of all illuminants, and is preferable to any other when the installation has been thoroughly well put up."

The electric light and power interests are of great importance in Italy, and the only rules in force in that country are those established by the government to protect its telegraph and telephone circuits. There are no insurance rules in Italy, and no insurance inspection of electrical installations, and places lighted by electric lights have the benefit of a diminished rate. In conclusion, gentlemen, your committee respectfully ask for more time to complete their work.

The report was received and filed and the committee continued.

In the discussion, Mr. S. A. Duncan referred to the two diametrically opposite quotations from the Underwriters' reports, and he hoped that this committee, in its pursuit of facts, would so sift the insurance statements that when the committee came before the Association again they would be able to say from their own standpoint what were facts and what were not.

Mr. P. H. Alexander said that the reason why the Phœnix rules showed such good results is because on the very first page is printed a very terse sentence, and very much to the point, viz., "In examining your tenders for work from different electric companies be careful not to accept the lowest tender until you have thoroughly examined all, and find that the work will be done just as good at the lowest figure as the highest given."

Mr. S. E. Barton, of Boston, characterized the report of the National Board of Underwriters, which was quoted in the paper, as the most asinine conglomerate mass of stuff that he had ever read. (Laughter.) The whole basis for the statement made in that report was founded upon the supposition—upon the assumption—that the one great fire in Boston last November was due to electrical causes; and as a matter of fact there was not a shadow of foundation for that assumption. (Applause.) That fire cost the insurance companies something like three and a half or four millions of dollars. It swelled the loss in a certain statistical paper that was published in this country as to fire losses chargeable to electric lighting more than five hundred per cent.; still it was only one fire, only one incident, and that one incident was without any foundation of authority. The number of reported fires which occurred last year from electrical causes was only seventy-three, as compared with one hundred and nineteen the previous year for the whole United States. The number of fires was actually twenty-five or forty per cent. less; but the amount of loss attributed to fires five hundred per cent. greater than last year.

Mr. A. F. Mason, of Boston, remarked that the Association ought to get up a set of rules of its own, independent of the Fire Underwriters', and offered the following resolution to that effect:

Resolved, That the Insurance Committee be instructed to give us independently a set of rules which it recommends, whether they be the same that shall be adopted, or whether they be changed less or more.

Mr. P. H. Alexander said, during the sessions of the Committee on Insurance the Underwriters' representatives were induced to do the best they could for the electric light fraternity. He also quoted Mr. Goddard of Boston: "If you and Mr. Jenks and Mr. Lovejoy say that my rules are wrong I will consider that they are wrong unless I can present an argument and convince you that I am right, because you have had experience in the business which I have not had."

Mr. J. A. Seely then moved, as an amendment to Mr. Mason's motion, that the chair appoint a new committee to formulate rules and regulations governing the installation of electric light, and that the members of that committee shall be active members of this Association.

After a lengthy discussion of the subject by Messrs. Alexander, Duncan, Cutter, Barton and Mason, the whole matter was laid on the table.

Dr. Louis Bell, of New York, then opened the discussion on

THE PROPER CLASSIFICATION OF THE LIGHTING POWER OF INCANDESCENT LAMPS.

I have raised this question for the consideration of the National Electric Light Association because it seemed to me a very curious thing that the whole subject of the classification of electric lights has not been more thoroughly gone into at previous meetings, and that there is now no general accord either in the classification of incandescent lamps as regards their light-giving power, or the methods in which that light-giving power shall be measured. It is rather a singular thing that light should be one of the most difficult things to measure absolutely that we have—not difficult to measure relatively, except in certain cases with which we are unfortunately only too familiar; but it is exceedingly hard to find anything like an absolute standard of light. The last desperate effort in that direction only resulted in perhaps as impracticable a standard as was ever brought before the consideration of scientific men. The question of classifying electric lamps is coming to be rather an interesting one, and one that is of importance to those who supply the lamps. We have various sizes and sorts of incandescent lamp, of all sorts of nominal incandescent candle power, the most usual in this country being the sixteen candle power lamp, but is there any common accord as to what is meant by a sixteen candle power lamp? I think not. And when the matter comes to be tested we find that it is not so. Of the various lamps which are now in use, rated at sixteen candle power nominally, some of them give the full candle power called for by their names, others give ten, twelve, fourteen or fifteen; and some of them give more than the rated candle power, while others give more or less than sixteen candle power, according as to the method of measuring which is used. We do not know at first sight whether it is fair to say that a lamp is sixteen candle power when its mean horizontal intensity reaches that figure, or when its spherical intensity reaches that figure, or when its hemi-spherical intensity reaches that figure. That whole question is open, and certainly ought to come under consideration by this body.

Then again, suppose we take one of those particular candle powers to be the standard; for instance, suppose that we take the horizontal candle power, which is perhaps the easiest to measure. Are we then in any better position? It might seem so at first, but a moment's consideration will show that the size, or rather the shape of the carbon filament has a very important bearing on the distribution of the light, and that consequently a light which gives in any one direction sixteen candle power may give considerably less in any other direction. Again, if we attempt to fix a standard direction, as for instance a direction normal to the plane of the filament for measuring the candle power we again get into trouble, for the reason that while the filament of a circular section gives a nearly equal distribution of light, a rectangular filament necessarily, theoretically and practically, gives an unequal distribution, the maximum intensity being at forty-five degrees off of the plane of the filament, or thereabouts. So that looking at it in any way we like we find that when we are speaking of a sixteen candle power lamp we may, or may not, mean the same thing. With the arc lamp we unfortunately know that the case is even worse, for instead of having an approximately equal intensity throughout a reasonable range around the lamp, we have a maximum intensity in a zone perhaps twenty degrees wide and deflected forty-five degrees below the horizontal plane of the arc.

Furthermore, we know only too well that the nominal candle powers of arc lamps are quite different from the real. The whole subject is in a tangle which at first seems almost hopeless. Heretofore it has not been specially important in the early stages of electric lighting, because people did not look so closely then into the exact conditions under which the light which they purchased shall be given; but as the electric lighting business comes more and more down to close competition and hard commercial lines it becomes more and more necessary to look after these things, and to define just what we mean by the lights which we contract to furnish, and to arrange some way by which there shall be general consent as to the meaning of the terms which we use.

I am happy to say that, as most of you know, the practice abroad tends towards something quite different from the candle power measurement; it tends toward the selling of electric energy by watts even when it is furnished as light—the kilo-watt hour being the British Board of Trade unit; and it is a question which I think we should take up, whether it is not perhaps advisable to classify by watts, a quantity which can be measured with the greatest ease, instead of by candle power, a quantity which is only measured with extreme difficulty. I pass over for the time being the difficulties in actual photometric measurement depending upon the difference in color, as they are subsidiary; but the great question seems to be to find some one definite thing which we can all agree to call a lamp of a certain size, whether it be sixteen candle power, or sixteen watts, or whatever you please to call it. Of course certain objections to the watt classification instantly arise, and among them is the possibility that it may tend to develop a type of lamp which will not be quite as efficient as those which are now generally used. That, of course, is simply a possibility, but it is one of the things that we want to bear in mind, for objectionable as candle power measurement may be, it is not well for us to be blind to the difficulties that come up with any other form of measurement. I desire to bring this subject prominently before the National Electric Light Association, because it is one in which I have felt a great deal of interest, and which I have had occasion to study somewhat, although perhaps more from the scientific side, in the matter of photometry. I believe it is a subject which calls for action on the part of the Association as a body, because I think the time is coming, and is in fact now here, when some such definite standard of measurement is needed and should be had; and this is the only body that has the power to make and to enforce any classification of light which may seem desirable after a consideration of the whole subject. I think that it is a case for action by the Association, and that it should take measures that shall lift us out of the very puzzling difficulty into which we have fallen simply through negligence, and through no fault or intent to deceive, but simply because the whole matter has been allowed to slide, and everybody has gone on in his own particular way instead of having, as we must soon have, something definite, something exact, something perhaps not scientific, but something which shall be at least empirically definite. (Applause).

Mr. A. V. Garratt, of New York—It must be a matter of pleasure to all of us to have this subject brought before this convention. There certainly is no one thing which has caused so much aggravation to the soul of the average electrician as the effort to find some basis on which you can talk about the candle-power of lamps. The trouble with trying to establish in America a practice similar to that of the Board of Trade in London is the fact, which we might as well recognize, that the National Electric Light Association cannot enforce anything. Some years ago I made no less than five hundred thousand figures for this Association to enable it (I was requested so to do) to measure wires. I made enough figures to reach from the city of Boston to the city of Providence. But, after having made those figures, and after they had met the approval of a majority of the members, we found that we were totally incapable of making anybody use them. Now, there certainly can be nothing better—or at least it is the opinion in England, and I think it is of the majority of the men in America—there is certainly nothing better for the unit of incandescent lamps than the kilo watt hour, provided there is proper precaution taken that the makers be not led to turn out a lamp which may possibly not be as efficient as the customer ought to have. Taking the kilo watt hour as the unit of energy for each lamp, and fixing the length of the life of the lamp, would seem to tie up our friends, the lamp makers, pretty tight with regard to what we should call a ten, a sixteen, or a twenty candle power lamp. It is quite impossible to make the purchaser of the lamp, the householder, ever talk about kilo watt hours. They will purchase what they know as a candle power lamp. But this Association might very properly suggest to the manufacturers of the lamps that a sixteen candle-power lamp, or a twenty candle-power lamp should absorb so many watts; and the unit of charge to the customer might be based upon watts as against hours. That might perhaps be best brought before us in proper form by the action of a small committee who could bring the subject before the next meeting of this Association in a paper, and if it is satisfactory to the body it might then be recommended to the lamp manufacturers. It is a thing which I do not think the general public will do very much with; and I do not see that it is a thing which the National Association can very well enforce. But I am positive that the kilo-watt hour would meet the approval of all the electric light fraternity in the country.

Mr. Alexander—The efficiency of the lamp to the consumer is of the greatest value only in some cases. If I have a water-power to run my central station, as the power does not amount to anything, I do not want an efficient lamp, but I want a long-lived lamp; but when I use coal at five dollars per ton I want a very efficient lamp. It is a fact that I have had from one railroad company a letter in which they ask me for a very inefficient lamp, because it costs them more to move their storage battery in and out of the car than the breakage of the lamps amounts to. They have by figures furnished by their electrician shown that a very short-lived lamp, say a lamp that lasts them but one-hundred hours, is cheaper than one which lasts them six hundred hours but needs a great deal of current.

Dr. Bell—The question of arc lamps I felt tempted not to touch upon for the reason that we have not been in the habit of measuring those anywhere in the world by the watt. The incandescent lamp is supplied frequently by meter, and that is what brings the matter of classification into special importance. We all know very well that the arc lamp is a great sinner in the matter of the distribution of light, and in the difference between theoretical and practical efficiency; but at the same time we ordinarily do not measure the power supplied to arc lamps in watts, as is getting to be somewhat the custom as to incandescent lamps. I should certainly be in favor of including the arc lamp in any action which the Association might take on this question.

The President—In making a test of the lamps of six different makers, I found that the variation in sixteen candle-power incandescent lamps is much more extreme than would be called a fair ordinary commercial average. I found that in two lamps the variation was from 17.25 candles to as low as 6.42 candles; and the watts per candle varied from 3.18 to 8.2. They were all new lamps.

Mr. Alexander—That is a subject that I am interested in; and I want to say that a lamp that will measure at the start twelve or thirteen candle power, after two hundred hours will likely give more light than a lamp which measures seventeen candle power at the start. All these matters have to be considered. If I desired to measure and to make an actual test I would measure the lamp after 50 hours burning, and then I would get a good result.

The President—We are now going through with tests and measuring every twenty-five hours. I will say, however, that a lamp which gave 17.25 candles was the lamp which at the end of 1,000 hours showed the least blackening of any lamp we had, but unfortunately it was not as efficient as I would like to have them.

Mr. Garratt then moved that the President be instructed to appoint a committee who shall report at the next meeting of the Convention on the proper classification of the lighting power of incandescent lamps. The motion was carried.

After a few announcements regarding social events the meeting adjourned.

THIRD SESSION, WEDNESDAY, AUG. 20.

The Association met pursuant to adjournment, Wednesday, August 20th, 1890, at 10 A. M.

The President—The first matter to be considered this morning in the order of business is the report of the Committee on Patent Legislation, of which Mr. Arthur Steuart is chairman.

Mr. Wilmerding—There does not seem to be any member of the committee here, and I move that the committee be discharged. They have not made a report for two or three meetings, as I understand, and I think we might as well give it up.

The motion was carried.

The President—Next is the report of the Committee on Legislation, Mr. C. H. Wilmerding, chairman.

Mr. Wilmerding read the following report:—

REPORT OF THE NATIONAL COMMITTEE ON LEGISLATION, TWELFTH CONVENTION.

Members of the Committee. Allen R. Foote, Chairman.

1.	Alabama	
2.	Arkansas	
3.	California	George H. Roe.
4.	Colorado	C. H. Smith.
5.	Connecticut	John C. English.
6.	Delaware	
7.	District of Columbia	George C. Maynard.
8.	Florida	
9.	Georgia	H. E. W. Palmer.
10.	Illinois	C. H. Wilmerding.
11.	Indiana	John Caven.
12.	Iowa	
13.	Kansas	L. A. Beebe.
14.	Kentucky	A. H. Barret.
15.	Louisiana	
16.	Maine	William R. Wood.
17.	Maryland	J. F. Morrison.

18. Massachussets............F. A. Gilbert.
19. Michigan.................J. E. Lockwood.
20. Minnesota...............
21. Mississippi...............
22. Missouri.................Joseph A. Corby.
23. Montana................
24. Nebraska...............
25. Nevada..................
26. New Hampshire............Alonzo Elliott.
27. New Jersey...............Henry W. Pope.
28. New York.................E. A. Maher.
29. North Carolina............D. A. Tompkins.
30. North Dakota ....Vincent S. Stone.
31. Ohio.....................Charles R. Faben, Jr.
32. Oregon...................P. F. Morey.
33. Pennsylvania..............A. J. DeCamp.
34. Rhode Island..............Marsden J. Perry.
35. South Carolina............George B. Edwards.
36. South Dakota.............
37. Tennessee ....
38. Texas....................
39. Vermont..................M. J. Francisco.
40. Virginia.................
41. West Virginia ....John B. Carden.
42. Wisconsin.................S. S. Badger.
43. Washington...............

1. At the Eleventh Convention this committee was instructed to "report for the action of the next convention, such changes in the Constitution as will in its opinion best provide for the membership and representation of State Associations in the National Association. (Volume VIII., page 249.)

After this action had been taken, the convention raised a special committee charged with the duty of making a general revision of the Constitution of this Association. In view of this, this committee has considered itself discharged from further consideration of the subject.

2. By action of the Eleventh Convention, this committee was instructed "to co-operate with the New York State Association in securing such an amendment to the Execution Law of that State as to require a special apparatus to be devised for the purpose, that shall generate a current of not less than 10,000 volts." (Volume VIII., page 248.)

No request has been received from the New York State Association for such co-operation, and so far as this committee is informed, no effort was made during the last session of the Legislature of that State to so amend the law. In the light of the reports made regarding the experimental execution that has since taken place in that State, it is now probably as clear to the public as it has been to this committee, that if executions are to be made by the use of electric currents, the amendment to the execution law recommended by this Association at its Eleventh Convention is demanded by every humane and equitable consideration.

(*a*) To give practical effect to the "Memorial and Statement," presented to Congress in the name of this Association by its president, which was presented in the United States Senate by Senator Hale, on August 5th, and was referred to the Committee on the Census, and ordered printed:—A Member of this Committee has prepared a bill which was introduced in the Senate of the United States, August 15th, by Senator Hale. It was read twice and referred to the Committee on the Census.

Your Committee recommend that the Association endorse this bill and urge its enactment, and that a resolution of thanks be tendered Senator Hale for his courteous and prompt actions regarding this subject.

This bill is as follows:—

51st Congress.
1st Session. S. 4,329.

In the Senate of the United States.

August 15, 1890.

Mr. Hale (by request) introduced the following bill, which was read twice and referred to the Committee on Census.

A Bill

To amend an act entitled "An act to provide for taking the eleventh and subsequent censuses" approved March first, eighteen hundred and eighty-nine.

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled, That, for the purpose of rendering the investigation of the electrical industries by the eleventh census thorough and complete in every detail, the Superintendent of Census, under the direction of the Secretary of the Interior, is hereby authorized and directed to make such subdivisions of the subject as may seem to him advisable, and to associate with the special agent now commissioned to investigate the manufacture of electrical apparatus and supplies and their uses, as special expert, the ablest person whose services can be secured to write the statement for each subdivision so made, subject to the supervision of said special agent; and the sum of fifty thousand dollars, or so much thereof as may be necessary, is hereby appropriated, out of any money in the Treasury not otherwise appropriated.

3. During the legislative season of 1889-1890, comparatively few State Legislatures were in session. During the coming legislative season, 1890-1891, a large number of State Legislatures will be in session.

If legislation touching electrical interests proves as attractive to the coming legislatures as it was to those that have recently been in session, there will exist an exciting cause sufficiently urgent to fuse all central station companies in every state into a compact organization for the protection of their mutual interests.

That ill-advised legislation will be met with in every state admits of no doubt. So long as would-be law-creators think it a factor of popularity to show in their legislative records that they introduce bills or advocated measures that are intended to be, or are in fact, antagonistic to the practical development of the electrical industries, such things will be done; or, so long as persons interested in patented apparatus and systems think they can gain a commercial advantage for such interests through legislative enactments, they will seek to secure such enactments regardless of their effect on electrical interests in general.

4. That those interested in the electrical industries in each State will be thoroughly organized and equipped to meet the emergencies that will be thrust upon them is very much in doubt. There is no sense of security equal to ignorance of danger. For those who are ignorant of a danger it has no existence. This, we fear, is the condition of most central station companies in this country regarding impending dangers from legislation. In view of this, the greatest service that may now be performed is to so state the threatening dangers that they can no longer remain in ignorance of them. To do this there is no need to speak of unreal things that are but creations of imagination. Sufficient material for the purpose is found in the record of things that are.

5. To show the tendency and animus of thought of those intrusted with the responsibility of legislating for the good of the people, a critical analysis is asked for the following brief reports on the work done by the legislatures of a number of States during the last season:

6. Connecticut.

(Senate Bill No. 4.) Chapter IX.

An Act relating to Attachments and Judgment Liens.

7. Massachusetts.

No better presentation can be made of the subject for the State of Massachusetts than to present in full the Report of the Counsel of Massachusetts Electric Lighting Association, made at its first annual meeting under date of July 8, 1890.

(Report was appended.)

8. New Jersey.

February 12, 1890, a substitute for "Assembly 113" was introduced "by Committee on Municipal Corporations." "An Act relating to electric telephone and telegraph wires and creating boards of electrical control in cities of the first and second class."

February 14, 1890, Assembly No. 6. Introduced by Mr. Smith and referred to Committee on Corporations:

"An Act in relation to telegraph, telephonic and electric companies in cities of this State."

Copies of these bills were in appendix.

9. New York.

January 21, 1890. In Assembly No. 160. Introduced by Mr. Whipple, read once and referred to the Committee on Ways and Means:

"An Act to create a board of electrical commissioners and to define and regulate its powers and duties."

February 20, 1890. In Assembly No. 598. Introduced by Mr. J. H. Stevens (by request), read once and referred to the Committee on Electricity, Gas and Water Supply:

"An Act authorizing water companies to manufacture and use electricity for the lighting of streets, public places and private buildings in cities, villages and towns within this State."

February 21, 1890. In Assembly No. 629. Introduced by Mr. Whipple, read once and referred to the Committee on Electricity, Gas and Water Supply:

"An Act to protect life and prevent accidents in the use of high tension electric currents."

April 4, 1890. In Assembly No. 1387. Introduced by Mr. Molan, read once and referred to the Committee on Electricity, Gas and Water Supply:

"An Act to create a State board of commissioners of electrical control and to define and regulate its powers and duties."

April 18, 1890. In Senate No. 618. Introduced by Mr. Erwin, read twice and by unanimous consent ordered printed, and when printed committed to the Committee on General Laws:

"An Act to create a board of electrical commissioners and to define and regulate its powers and duties."

April 18, 1890. In Senate No. 634. Introduced by Mr. Erwin, read twice and by unanimous consent ordered printed, and when printed to be committed to the Committee on General Laws; report favorably from said Committee, with amendments, and committed to the Committee of the Whole:

"An Act to create a State board of electrical control and to define and regulate its powers and duties."

(For copies of these bills see appendix.)

In transmitting copies of these bills to the Chairman of this Committee, J. W. Eaton, Jr., attorney, of Albany, N. Y., writes as follows:

"None of these bills have become laws. I am of the opinion that an attempt will be made next year to rush through the legislature a bill combining most of the principal features of those sent you unless some determined opposition develops in the meantime. I believe there is also a movement in favor of adding an electrical expert to the present railroad commission and putting the matter under their charge. There was no law of general interest affecting electrical lighting passed this session."

10. Ohio.

The legislature of this State was urged to action by the following highly electrified paragraph in the Inaugural Address of Governor Campbell: (See reports in daily press, January 13, 1890.)

"The application of electricity is rapidly opening up new fields of legislation. Unless something be done to prevent the sacrifice of life daily resulting from the effect of electrical wires, the companies which put up and control them will have grown so rich and powerful that the passage and enforcement of proper laws will be difficult. Municipalities have attempted to enforce regulations for protection from such dangers, but without satisfactory results. The duty of investigating the generation and distribution of electrical currents is one which presses upon you. The investigation should be prompt and thorough; the result thereof made public; and such action taken as may, in your judgment, throttle this evil in its infancy."

The following bills were introduced into the Ohio legislature at the last session:

"A Bill concerning electric wires and circuits dangerous to life and property."

"A Bill to authorize the construction of subways and underground conduits in which to place electric wire cables and other electrical conductors in cities, towns and villages of this State."

"A Bill to regulate electric light companies so as to protect the public from accident and damage from the same."

"A Bill relating to electrical conductors for electric lighting in cities of the first grade of the first class, and the removal of overhead wires."

11. Virginia.

Senate Bill No. 238. A Bill for the prevention of danger from electric currents. Patron—Mr. Lovenstein. Referred to the Committee on General Laws.

12. While this report does not completely cover the ground, owing to difficulty experienced by this Committee in obtaining copies of bills and definite information regarding action taken on them, the showing is sufficient to demand attention from every one interested in the electrical industries, and will enable them to form some idea of the legislative work that is near at hand during the season of 1890-1891, when the legislatures of some thirty-seven States will be in session.

13. This Committee desires to call attention to the fact that all legislation is directed to the regulation of the use of electrical apparatus, not to its manufacture and sale. This use includes all forms of apparatus, the telegraph and telephone, as well as the generation and transmission of electric currents for light and power. Such legislation affects primarily the interests of those who have their capital invested in plants for furnishing such service and thus establishes a community of interest between them. The interests of manufacturing companies and supply houses in such legislation is secondary, as they are only affected through the effect on operating companies. For these reasons, and in view of the fact that legislation is confined to State legislatures, there is a real necessity for the operating companies in every State to form themselves into associations for the development and protection of their mutual interests.

14. In analyzing the subjects of legislation, this Committee would be untrue to the interests it represents should it fail to bring to notice the fact that most of the so-called antagonistic legislation is not the result of a popular demand, but issues from those interests that seek a commercial advantage by legislation that, either directly or by implication, would create conditions favorable to their particular apparatus or systems. A diminution of efforts of this kind may be reasonably expected, as the art of generating, distributing and using electric currents becomes more and more a matter of common information and electrical systems approach more nearly to the zenith of their development.

The President—The Committee on Legislation have in their possession, and it will be transferred to the secretary to be incorporated in the volume of proceedings of the convention, all of the bills, in full, referred to in that paper, and of course they will be at the service of the central station men; and I have no doubt they will prove very valuable indeed as showing the general trend of the legislatures throughout the country.

I learned with much pleasure this morning of the presence here among us of the first man who ever occupied the chair of the National Electric Light Association; and, without consulting the convention, I shall venture to appoint two gentlemen to escort him to the platform; and I think we shall all be very glad indeed to hear a few remarks from him. The chair will appoint Vice-President Edgar and Mr. DeCamp as such Committee.

(Mr. Edgar and Mr. DeCamp escorted Mr. George S. Bowen to the platform.)

The President—Gentlemen, I have great pleasure in introducing to you Mr. Bowen, one of the early fathers, who has now come to take a look at his child. (Applause.)

Mr. Bowen—Mr. President and Gentlemen of the Electric Light Association: You certainly have placed me under great obligation by the graceful compliment which you have conferred upon me in asking me to stand before you and look at the child that was born some six years ago. It is true, as the chairman has stated, that I called a convention to order in Chicago, and I did it after some weeks of labor in sending out circulars, etc., inviting the men who were engaged in the electric lighting business to get together, to become acquainted, to rub together slightly and see what the effect might be. My own opinion was that it would be useful to us all, and to that end we created a little committee in Chicago, and I was made the chairman of it, and I had the honor of sending out those circulars, and in responding to the circulars there were about one hundred and fifty gentlemen who came from all quarters of the Union to Chicago. I mention, as I stand before you, an incident which occurred, which often has come to my mind, and it was this: Mr. Morrison, of Baltimore, said to me, on being acquainted, "What are your plans?" I said, "Well, we have no underground plans or overhead plans. My plan has been simply this, to invite the electric light men to come together, to become acquainted with each other, and after I have called the convention to order and you are all in the room which has been provided for you, my duty is done. I have no plan at all, because I have the utmost confidence in the capacity of the men that have taken hold of this great business, the lighting of the world, to take care of themselves, and so I have made no plan whatever." (Applause.) And so you see, gentlemen, that it gives me the greatest pleasure in seeing the growth and the activity and the real benefits that have come to the country from this organization of the electric light fraternity. I cannot go anywhere scarcely, it may be the most remote town—and I have been all over this country and a good deal over Europe during the last year, and I say to you that America to my mind seems to be ahead of Europe in the electric lighting business; and so what shall we finally come to? I do not make any prediction, but I say to you, gentlemen, you have only opened the first page. I expect to live to see the day when all these little towns all over the country shall be illuminated with electric light, and we shall have not to grope about in darkness as much as we have heretofore; because some of you gentlemen are going to develop plans by which all the world may have the light at an expense so nominal that they cannot afford to be in darkness; and so the world will be indebted to the electric light men for all of that.

Mr. Weeks—Mr. President, on behalf of the Executive Committee, I would report to the Convention their recommendation that Mr. George S. Bowen, who has just addressed the convention, and to whom more than to any one else this Association owes its existence, be elected an honorary member of this Association.

The motion was duly seconded and carried.

Mr. Bowen—Mr. President and gentlemen, you have placed me under still renewed and lasting obligation. I assure you that I appreciate this delicate and beautiful compliment to me in all its best phases, and so I only wish you the very best that God Almighty can give to you all through your lives. (Applause).

The President—We will now resume the regular order of business and proceed to the consideration of the report of the National Committee on Legislation.

Mr. Mason—Mr. President, I notice that this report now under consideration, and recently read by Mr. Wilmerding, refers to a bill that is now in the Committee on the Census, the Committee of the Senate. I beg to offer the following preamble and resolutions:

Whereas, On the 15th of August, 1890, the honorable Senator Eugene Hale, introduced in the Senate of the United States a bill to amend an act entitled an Act to Provide for the Taking of the Eleventh and Subsequent Censuses, approved March 1, 1889, and

Whereas, The said bill was read twice and referred to the Committee on the Census, and

Whereas, In the opinion of the National Electric Light Association, the passage of this bill is essential to render the investigation of the electrical industries by the Eleventh Census thorough and complete; therefore,

Resolved, That the President of this Association be requested to express this, our opinion, to the Committee on the Census and urge the Committee to favorably report to the Senate the bill referred to.

Resolved, That the thanks of this Association be tendered to Senator Hale for his services in the matter of the bill above referred to.

The President—Gentlemen, you have heard the preambles and resolutions offered by Mr. Mason. What is your pleasure?

MR. DECAMP—I move they be adopted.

The motion was duly seconded and carried.

THE PRESIDENT—Are there any remarks on the same question? If not we will now listen to the paper on Municipal Lighting, by M. J. Francisco, of Rutland, Vermont.

Mr. Francisco read the paper. See page 210.

THE PRESIDENT—The Chair will announce the appointment of the Committee of three on the proper classification of the lighting power of incandescent lamps: A. V. Garratt, Louis Bell, P. H. Alexander.

The paper which has just been read is now open for discussion. Are there any remarks on the paper just presented by Mr. Francisco?

MR. WILMERDING—I move a vote of thanks to Mr. Francisco for the able way in which he has set forth this matter. I hope that the paper will have a circulation all over the country, and do some good; and I think that the Association ought to thank Mr. Francisco for the labor and care that he has taken in preparing this valuable paper.

MR. DECAMP—I think that the most lasting compliment which can be paid to the author of that paper will be for this Association to authorize its printing for general distribution among the members, so that they may all have an opportunity of making direct use of it. I do not think that a paper of that kind should pass without very general remark by this Convention upon it. Personally, I do not feel competent to do it, because I have not been touched as yet in that direction. I would probably be a little more lively at the present time if I had been. But, in listening to the paper these things struck me. It is known to every man on the floor of this convention who is engaged in the business of electric lighting, that municipal ownership of electric light plants has its origin among a few politicians who wish to add another plum to the public pudding that they may pluck it. There is no question about that. There is no sentiment in it; it is a simple matter of fact. The public who have to pay for this know nothing else, excepting, perhaps, the two or three points which the public know fully as well as their servants in these matters; and one of them is the fact that there are certain things in connection with municipal management that are always notably extravagant. There is one point that might well go forth in some shape, and which would wake the people up a little who have the final decision of these matters. I suppose that it is pretty nearly a correct statement that from fifty to sixty per cent. of the total cost of producing electric light is in the labor account alone. It is one of the most difficult problems that electric light companies have to contend with. It is something that is the hardest to control. Now, if there is anything under God's Heaven in which there is extravagance practiced by municipal governments it is the matter of labor. For a municipal government it invariably takes two men to do one man's work. They are as a rule extraordinarily extravagant in the matter of labor, to say nothing of the other elements of political patronage which enter into it. But I would like to see this report printed, and I would like to have copies for free distribution among the members. I will pay for it if it cannot be done in any other way.

JUDGE ARMSTRONG—I feel myself very much obliged to Mr. Francisco for this paper. The instances he cites were used as against our company about a month ago when we made our annual bid for lighting our city. It so happened that our general manager had the answer ready to the most of these criticisms, and yet a new member of the City Council, flushed with his victory at the polls, and believing that the eyes of the whole community were upon him, and that upon his shoulders rested the protection of the tax payers against a grasping monopoly that had the lighting of the streets, went into the City Council and claimed that our bid for lighting the city was entirely too high, and that Bay City, Bangor, Dunkirk, and all the rest were having the lighting done at so much less. The answer to all those criticisms was made in such a manner that nothing further could be said. But how much better we could have answered it had we just this paper to hand to every member of the City Council, so that we could say to them, there is the author's name; there are the facts; now say what you please concerning it. There was one thing further—and possibly an opportunity will come to speak of that later—which we cannot so well answer. There were parties who desire to sell one or two dynamos to other companies that inspired other bids. We may be able to speak of that after a while under another subject. I want to endorse very heartily Mr. De Camp's suggestion that we have this printed by the Association for distribution throughout all of the cities where electric light is furnished by private corporations; and the facts contained in this paper will do much in the creation of a proper feeling, a kindly feeling from the taxpayers and citizens towards our companies; and when we shall have accomplished that, I think we shall have done a great good in the way of making popular our work, and in the way of enlightening the people, and where we expect to get our returns, and what we furnish for it, and how we furnish it.

MR. BARRETT—I notice, in looking over the account here, that I am asked, or the city electrician is asked, some very pertinent questions. I do not advocate the absorption of a commercial business by any municipality. I never did. The city of Chicago's electrician has simply performed the orders which he received. This statement strikes me as rather a singular thing. I find here that the cost of municipal lighting is set forth very clearly, very extensively and very expensively; but I have never, in all my experience with this Association, seen a tabulated statement of what it costs to light a commercial plant, per light—never in all my life. Now, this is what strikes me as being rather singular: Why cannot a city light its streets as cheaply as a commercial company can? Isn't the market open to the city to purchase its material? Can't it hire its laborers as cheaply as anybody else? Has it not an officer, and is he not compelled to report expenditures just as clearly and distinctly as does the head of any private concern? Why should it cost the city more than it does anybody else? I have charge of the municipal electrical service of police, fire, board of health, and the city lighting. I get economy as to materials. I do not claim that I can light a lamp any cheaper than anybody else. I do not claim that it costs me any more than it does anybody else to light a lamp, except in labor alone. We do have to pay more for labor than anybody else. If I could get this lighting from corporations for what it costs us to maintain our own lights I assure you, gentlemen, that I would recommend it.

MR. GARRATT—It seems to me that the simplest reply which can be made to the question why, or why shall not, a city do its own lighting, will be found right in the words of President Cleveland on the tariff question, when he said: "In this matter we are dealing with a condition of things and not with a theory." If we were dealing with a theory, there is absolutely no reason why a municipality cannot do any business that any citizens are engaged in more profitably than the individual citizens can do it themselves. We are dealing with a condition of things which, in the United States, under our form of government, is this: That the government shall not in any way interfere with the rights and privileges, the pursuit of happiness and the success of its citizens; that the citizens themselves shall do the industries of the country; that the government shall be as small and as insignificant as is possible to hold people together in a civilized community. That is the simple question. Theoretically speaking, I see no reason why a municipality cannot bake the bread for the people, or why it cannot butcher the beeves. There is no reason why, except that in the condition of things under which we are living it is entirely unfeasible.

MR. DE CAMP—I think Mr. Barrett put the true question when he said, "Why can't it be done?" Well, there ought not to be anybody more competent to answer that question than Prof. Barrett himself, because he is right in the business; but he don't do it. Now, in reply to the other point, in which he says that no commercial plant has come forth to say what their lights have cost them. There is a plain answer to that. That has not yet become necessary, and it is not customary, except by the lowest bidder. Now, the figures which Prof. Barrett has named and set forth and published broadcast over the world, have been so much lower than any commercial company has ever produced their lights for, under anything like similar circumstances, that that thing is not at all necessary. A commercial company who have stockholders to serve, and who are under certain confidential obligations, which are generally recognized, are not in the habit of publishing that sort of statement. So that I presume when the commercial lighting comes down to a point where they can produce the lights at a less cost than the municipal plants are now costing, we shall hear just what they cost; and they can very well afford to wait until that time.

MR. DUNCAN—Judge Armstrong has hit the case fairly well when he stated the case of the representative of the municipal body who lacked information. I am not here to defend municipal bodies. I know something about the manner in which municipalities are conducted. While my friend De Camp thinks that every man who has ever had any connection with a municipal body must naturally become dishonest, I differ with him. (Laughter.) I believe that the same percentage of honesty will prevail in municipalities as in the Electric Light Association. But, sir, the information that the gentleman from New Jersey had to put before his man was meagre. What we want to do at the present time is to place the statistical information, which has been prepared by Mr. Francisco with a great deal of labor and care, in such shape that members of this Association can use it when this question arises in their cities or towns. I do not blame that man in the New Jersey town as much as I do the Judge. I think it was his duty, as he was the most interested party of the two, to obtain this information at any cost. We are to day all on the same platform and we are going to use this information where it will do some good. I hope the resolution will pass.

MR. DE CAMP—Mr. Chairman, I have got a question here for Prof. Barrett, but he seems to have left the room. The question is, whether, in the published statement that the Chicago lamps cost sixteen cents per light, he includes interest on investment, his salary and depreciation.

MR. FRANCISCO—I can answer that for Mr. Barrett. I have a letter from Prof. Barrett in which he states point blank that he does not include it.

THE PRESIDENT—I think the question is answered.

MR. HAMMER—I have a suggestion which I think is very pertinent to this subject, which comes from across the water. I lived in the city of Paris last year and I became acquainted with some of the gentlemen connected with the municipal government there, and among them the chief engineer of the city, who had charge of the municipal lighting affairs, and I learned some things which have considerable interest as bearing directly on this subject. The city of Paris some time ago offered a prize for the best electric meter that was brought to their attention. Tests were conducted, and there is to be, I believe, a second series of tests. It may also be known by many of the gentlemen here that the city of Paris, at a very considerable expense, has placed in one of the sections of Paris a large plant on the direct current system, and also a large plant on the alternating system. The city of Paris, a great many people have supposed, was going into municipal lighting, and that these experiments were intended as leading up to the city of Paris putting in enormous central stations for doing the general lighting of the city. I asked the engineer if he would give me an expression of his opinion of just the status of the government in regard to this matter, and he said it was this: That the municipality of Paris appreciated that electric lighting had come to stay, and it was an enormous industry, one of great importance to them, and one in which the French people were backward in taking hold and pushing forward; and that they desired, as has always been characteristic of the French people, to encourage the arts and sciences, and in this particular case they wanted to encourage this industry. With that end in view they took a representative direct current system and a representative alternating current system and placed them in one of the sections of the city and said: "Now when we are through with the test, the system which has given us the greatest satisfaction, and which we can endorse as being the best for the city of Paris, will be applied, and the municipal lighting will be done by that system." And I asked him about the relation of the meter tests, and he said they were very similar; he said the meters were to be tested, prizes awarded, and the city of Paris would retain the privilege of utilizing any meter which they decided upon as being the best, but that that utilization would be only very limited, to be used in these experimental stations, and that the city of Paris did not propose to go into the manufacture of electric light any more than they were going into the manufacture of any other commodity; that they did it entirely to foster the industry. (Applause.)

THE PRESIDENT—Mr. De Camp, Prof. Barrett has now returned to the room, and you will now have an opportunity to ask him the question.

MR. DE CAMP—Mr. Francisco answered the question that I asked, whether the published statement of the cost of sixteen cents per night per lamp included interest, his own salary and depreciation.

MR. BARRETT—It don't include interest; it don't include water taxes, rent—or, yes, it includes depreciation. We don't have any depreciation. (Laughter.) We buy a class of goods that will last. I will say that sixty-two miles of wire last year cost me $16 for maintenance—underground.

MR. DE CAMP—How many lamps did you have on?

MR. BARRETT—I don't know.

MR. DE CAMP—That is a very important factor.

MR. BARRETT—I will not attempt to answer it; I don't know. I don't know the amount of wire that we have in that district. But there is another consideration that I want to mention and that is this: That by the action of the council the gas and the oil and the electric light is one fund, and the electrician has charge of all, and of course it would cost less. I have endeavored to be honest with you, gentlemen, and I have endeavored to get an honest expression. (Applause.)

MR. ALEXANDER—Mr. President, it seems to me Prof. Barrett is right in so far that when the municipality makes an appropriation and comes within that appropriation, or goes outside of it, the proper office states, "We have expended in this department so much money." Now in the Fire Department you are never asked whether you are to have the apparatus capitalized, or the buildings capitalized, but you say, "Our Fire Department cost us this year $7,445." Why should you make a difference as a municipal officer in that particular branch? These are reports that are published. Central station men want naturally to give the stockholders of their companies a complete statement, not as to what the lights cost, but as to how much money they have made or lost during the year, while the municipality from year to year have new appropriations made, and old apparatus is replaced by new appropriations.

MR. BARRETT—The only report that I make is the gas and oil. I show the comparative cost between gas and electric light and oil—always in favor of electric light.

MR. T. C. SMITH—There is one point on this question that I think we should look at fairly. There is no doubt that a municipality under certain conditions can, and under all conditions ought to be able to, run its plant cheaper than any corporation. On the other hand, I think there is very little doubt that it very seldom does. The remark that Mr. Garratt made about dealing with conditions and not theories I think is a very pertinent one; and I think if you will examine into the administration of a good many of the larger European cities you will find that a good many of those cities do own their own gas works and water works and do furnish gas and water as cheaply as a corporation would; but on the other hand, you will find a very large number of cities, and especially the very large ones, who do not own the gas works or water works, and yet water and gas are supplied at a far less rate than when the cities do own them. Another thing you have to take into consideration is what is meant when you speak of the cost of running gas works in the city, or an electric light plant. In Philadelphia they have a good chance to supply gas as cheap as anybody. Their gas plant lies by the water; they can get cheap transportation for coal; they have an excellent market for coke and all waste products, and they charge $1.50 for about the meanest gas I ever saw. Not only that, but the city pays $150,000 for gasoline lamps. I think that $150,000 should be charged right into the gas works, for the city is supposed to do its lighting and yet it pays an outside corporation that money. I think there are a good many things that we want to look at very carefully, and the more this thing is probed the more baseless you will find the claim to be that the city does run the lights cheaper; and I think Mr. Francisco's paper ought to be published as widely as possible, because when you go into any average Council Chamber and listen to the talk you will find very soon that it is not facts that are taken into consideration but talk; and if you have good solid facts that you can put to these people that can not be controverted, it will have more weight with the public than anything else. I have seen these statements of the cost of lights in the various cities, that have been sent around, and some of them are very wonderful, as Mr. Francisco has shown them to be.

MR. DECAMP—Mr. President, I wish to make a statement of fact. The city of Philadelphia has owned its gas works for a great many years. In the annual statement of the Board of Gas Trustees they always showed an enormous profit; but under the new charter it was taken out of the hands of the Board of Trustees, and for all moral purposes it is generally conceded for the better. It is a matter of history that the gas trust in Philadelphia was one of the greatest sinks of corruption in the whole city, and on moral grounds, if on no other, it was taken from the Board of Trustees and placed in the Department of Public Works, which in point of honesty has the confidence of the whole community, unpopular as it may be personally. They found that the capacity of the present established plant was not sufficient to supply the needs of the city for public purposes, and for private purposes too —because they furnish light to private parties. There was no money to build additional plant. The next thing was to contract with a new company for the furnishing of three million feet of gas a day to make up the deficiency. They contract for that at 37½ cents per thousand feet delivered in the holder. They sell it for $1.50 a thousand, and according to the official report published for last year, show a profit—I don't know just what the amount is, but if they had not had the profit on these three million feet a day of the difference between 37½ cents and $1.50 which they sold it for, with all the increased effort and with the prestige of an honest, business-like administration of those affairs, the gas department of the city of Philadelphia would have shown a very heavy loss for the year 1889, even with gas at $1.50 a thousand.

MR. ALEXANDER—I do not believe in municipal plants, but I hope the statements that are made here to go out as printed will be fair to all parties. 37½ cents is the price of gas in the holder —the gentleman did not say that is not including the cost of distribution and leakage in the pipes, which will diminish the profits of the city of Philadelphia on that three million feet considerably.

MR. DUNCAN—He said in the holder.

MR. DECAMP—Mr. Alexander calls attention to the fact that there is the cost of distribution.

MR. ALEXANDER—Distribution and leakage in pipes.

MR. DECAMP—I know that. I will call that part of the statement back. I am not certain about it.

MR. T. C. SMITH—The city pays for delivery into the holder, but the gas is distributed in exactly the same service; there is no additional service laid down. You have the cost of distribution in the same pipes.

MR. FABEN—An analysis of the statements that they made shows that if their business was self-sustaining before this three million was added, the buying of this three million feet at 37½ cents and selling it at $1.50 ought to give them a profit of the difference between those two prices; but they did not realize the difference between the cost of three million feet at 37½ cents and the sale at $1.50, which would show that their business before they bought this three million feet at 37½ cents was not self-sustaining.

MR. ALEXANDER—That is exactly what I am getting at, that the difference between 37½ cents and $1.50, is not the profit, but they realized a profit beyond the cost of distribution.

MR. DUNCAN—I should like to ask one question of this committee. While this is a very gratifying report, it does not seem exactly fair that we should make a statement in regard to a company which is furnishing lights to a city, on a bid, unless we ask whether they take into account or not their other business in connection with it; whether they make a separate item of that alone, as run as a separate business, which the municipality does. You

have got to get them on the same basis to make a fair statement. Did the Committee on Data get any information of that kind?

THE PRESIDENT—This is not the report of the Committee on Data that is under consideration.

MR. DUNCAN—The committee need not answer it now.

MR. DE CAMP—It is a pertinent question to come in here. I have always felt perfectly safe in making these statements, because whatever doubt there was in it was on the other side. I do not, as far as I am concerned—nor am I able, and I do not see how I could do it—eliminate it and get the fixed cost of the special city service as distinct from our general service; but if you take it on the hour basis you can make a very safe approximation. The city lighting in the city of Philadelphia, I think, averages about eleven hours and some few minutes, ten to twelve minutes. Now the general average of the whole business, including commercial, is practically the same thing, eleven hours. But a large portion of the commercial business, if you took the commercial business by itself, would not average probably more than six hours. Now if you eliminate that you have got the advantage of the short hour service in commercial business, and if you were to eliminate all commercial business and take city business, whatever difference there is would be against the city, because you would have nothing to offset in the way of short hours. I am perfectly safe in saying that our general average is a fair one when you are discussing the matter of municipal lighting.

THE PRESIDENT—Unless there are some further remarks, Mr. Bowen will close the discussion.

MR. BOWEN—I have listened to the discussion with a great deal of interest, having had something to do with city lighting myself, and I rise especially for the purpose of approving and commending the suggestion of our friend from Philadelphia, Mr. DeCamp, who advises the publication of this paper for general free distribution. I know of nothing that will dispel so much darkness as light; and this paper throws a good deal of light upon this subject; and I should recommend and should be quite willing to pay my proportion for the publication of ten or twenty thousand copies of that paper, that it might be distributed very generally all over the country; and I am quite sure that if that paper were sent to a great many towns in the United States, to aldermen perhaps, or the mayor, or some of the principal persons there, it would create a disposition to look into the subject of electric lighting and see if they could not improve and benefit the town by a better system of illumination; and I am quite sure that that would be one of the very best advertising documents that electric light men could send out. Although I am out of the electric lighting field now, I extend my cordial sympathy to all of the gentlemen who are in the electric lighting business who are furnishing cities with light and have to deal with city councils. Criticisms are frequently made; I have been the subject myself of newspaper criticism to such an extent and to such a degree that I have been almost immortalized in my own locality as the great coupon clipper of an electric lighting company that made its lights without any cost. In fact, I have been charged with producing electric light without the consumption of any coal. The information which is conveyed in this paper will be very useful and will produce a great deal of excellent thought, and you will get good results from it. In this statement regarding the lighting of the city of Dunkirk, it is said that after using their machinery for a year and eight months their lines are in a better and more perfect condition than when they first started. That differs from what my experience was, because about the first year after I put in my plant I had to build it all over again, and I have heard of others that had to do the same thing; and that is why I suggest to you that whenever you do a thing do it well. On that point I want to say one thing. Prof. Barrett enjoys the confidence of every man in Chicago, whether he is a democrat or a republican. They all refer to him as an absolute authority, and he has full power to carry on the electric light business and his bills are paid. There is the great advantage that he possesses. I happen to know of a city where a while ago they wanted a few brushes, and they sent the city clerk to the nearest seaport town, and that happened to be Chicago, to buy a couple of pair of brushes. That cost the city some fares, etc., and gave the man a chance to go to Chicago. There cannot be a thing done unless a committee passes upon it. If a man wants to sell a few carbons they call the committee together; and all of you know who have had anything to do with selling carbons, what you have to do when you meet a committee. (Laughter.) All those things can be avoided by having absolute authority, as Mr. Barrett has. I congratulate him, and I congratulate the city because he is a man of great capacity as an electrician, and is an honest and square man.

THE PRESIDENT—The question is upon the resolution. Shall we print a certain number of copies to be left with the Executive Committee for general distribution?

The motion was carried.

THE PRESIDENT—Next in order is the report of the Committee on Resolutions, A. F. Mason, Chairman.

MR. MASON—To your Committee on Resolutions have been referred only two. I will read the first:

"That a Committee of five be appointed, of which number the President of the Association shall be ex-officio one, the other four members to be appointed by the President, who shall offer their services to the authorities of the Columbian Exposition with a view to securing suitable facilities for the proper exhibition of electrical manufactures and appliances, and in general to work for the advancement of electrical interests and to offer the authorities of the Columbian Exposition the co-operation of the National Electric Light Association to aid in making the Exposition a success."

Your Committee recommend that this resolution be passed.

The second resolution which came to our hands is the following:

"That the Committee request the selection by the authorities of the Columbian Exposition of Mr. John P. Barrett to have practical charge and control of the electrical department of the World's Columbian Exposition."

Your Committee, recognizing the fact that, while before the present gathering, probably the larger part of the members of this Association had personally recommended the appointment of Mr. John P. Barrett by the authorities of the Columbian Exposition to the charge of the electrical department of the World's Columbian Exposition, yet that, on the floor of the Convention, members have expressed the opinion that it is outside the province of this Association to offer such recommendation, your Committee, therefore, return this resolution to the Association, suggesting that it act upon the same without suggestion from its Committee. (Signed by the Committee.)

THE PRESIDENT—Gentlemen, you have heard the first resolution reported back by the Committee, that a Committee be appointed, of which the President shall be ex-officio one, and four other members who will volunteer to offer their services to the authorities of the Columbian Exposition and co-operate with them in securing an exhibit of electrical apparatus, I suppose. What action will you take upon it?

MR. BROWN—Mr. President, I move that the report of the Committee as to that resolution be adopted. Seconded by Mr. Alexander.

THE PRESIDENT—The second is a resolution that the Committee request the selection by the authorities of the Columbian Exposition of Mr. John P. Barrett to have practical charge and control of the electrical department of the World's Columbian Exposition. The Committee return it without recommendation.

MR. ALEXANDER—I move that that resolution be laid on the table. Seconded by Judge Armstrong.

SECRETARY FOOTE—The vote as corrected, eliminating two votes that were challenged, stands 26 yes and 17 no.

THE PRESIDENT—The motion to lay on the table has prevailed.

On motion of Mr. De Camp, properly seconded, the Convention adjourned until 4 p. m.

WEDNESDAY, AUGUST 20.—AFTERNOON SESSION.

The session was opened by Mr. A. J. De Camp, of Philadelphia, who delivered an address on "The Value of Detail in the Care and Labor of Electric Light Stations." (See page 212).

During the discussion which followed the reading of the paper Mr. De Camp said that if a person wanted to give a contract for a light to burn six months in the summer, that man would be entitled to a very low price, because he was going to rent when the station wanted all the load it could get. But such conditions did not exist to any extent. The highest that he had ever had since he had been in the business was not over eighteen or twenty exclusively summer lights. It was not followed up because it was not considered a paying business.

MR. DE CAMP also stated that the price for a twelve month's contract for half night lights is 65 cents; for eleven months, 62½ cents; for ten months, 70 cents; for nine months, 75 cents; for eight months, 80 cents; for seven months, 85 cents; and for six months, 95 cents. For all-night lights he adds fifteen cents to each one of the above prices; that is, he charges fifteen cents more for all night lights than for half night lights.

In reply to a query from Mr. Wilmerding, Mr. De Camp said that there was a discount of ten per cent. if bills were paid before the 10th of the month, but that contracts were made without reference to the ten per cent. deduction. He also stated that in the effort to establish the new rules he lost about five lights on the six months basis.

MR. C. H. WILMERDING, of Chicago—In Chicago, on the twelve months' contracts, we charge 65 cents, with 15 cents discount, per lamp per night. But I am speaking of the arc light only. Where the wire is paid for by the customer it lets us out on the short contracts. If a customer does not want it for more than three months we have got to have some rule established by which we can give it to him; and they are willing to pay for what time they use the lamp. In that case it is the same to us whether the customer uses the lamp for three months or for a year. So long as he pays for the actual cost of construction, and we are getting our regular rates out of him, we will get out whole.

If a man wants the service, and wants us to charge for only the summer, then we have got to let him have it or else he will use something else. I think that we have got to accomodate ourselves more or less to the public demand.

MR. DECAMP—As for competing with gas I may say that I do not think that we have an arc light in service to-day that is burned with any reference to the cost of gas. I have never been asked to make a contract in that way.

MR. WILMERDING—My experience has been just the reverse. I find that they will figure exactly just what their gas is costing and then see whether they can get the electric light at a sufficiently small advance over the cost of gas to warrant them in paying for it. Six or seven hundred of our arc lamps are day lamps, which are burned in large dry goods stores where they have got to use artificial lights; and they would use gas if they could not get the electric light for what they consider a reasonable price.

MR. S. J. HART, of New Orleans—It seems to me that this is a question which can only be regulated by the managers of the different companies, for the reason that the conditions are different with different companies. Furthermore, the legislature of our State, at its last session, which adjourned thirty days ago, in one house passed an enactment regulating the price of gas and of the electric light, but it failed to become a law for the reason that the legislature adjourned before the bill reached the House of Representatives.

MR. A. M. RENSHAW, of Washington, D. C.—I will state that our experience in Washington has been substantially the same as it has been in Philadelphia. We found that we had a large demand for lighting in the fall months, commencing along in October, November or December, and generally ceasing about the first of the year. We found that it would be impossible to supply that demand without doubling, or perhaps even trebling, our capacity. We found, furthermore, that we could not charge a price that would warrant us in doing that kind of a business. The result was that for several years we have had to have two terms for the electric light, one for six months and one for twelve months. We rent no lights for a less term than six months under any condition whatever, and we have very few lights rented for six months.

The next paper, by Mr. H. L. Lufkin, of New York, on "The Proper Basis for Determining Electric Motor Rates,"[1] was then read by Mr. Jos. Wetzler.

In the discussion which followed the reading of Mr. Lufkin's paper, Mr. Ch. Wirt, of Chicago, remarked that it was a little bit too fair to the gas engine. He was not very familiar with those figures at present—not as familiar with them as he was at one time. He thought it would be a very large gas engine, and a very good one at that, which would give a horse power hour for twenty cubic feet. He was informed that with one kind of gas it would burn as high as fifty feet, that is, fuel gas. He quoted the result of a test where twenty-two feet was used per horse power per hour, but he would not expect to get that result with commercial work and small engines.

MR. FABEN, of Toledo, stated that the Otto gas engine people, of Philadelphia, will warrant that the engine will not consume to exceed twenty-two and a half feet per hour per horse power with an average commercial illuminating gas.

DR. LOUIS BELL, of New York, said that he had had occasion to handle in the last year and a half a large number of tests, both in this country and in Europe, and very few of them showed less than 23 or 24 feet of gas, although this figure was sometimes slightly better. Then, further, it was interesting to raise the question as to whether this so-called 20 feet per horse power hour is brake-horse power hour or indicated horse power hour. As a rule the friction comes in to play an important part, and, further, the amount of oil used in gas engines is very considerable, so that in one prominent test in England a short time since an allowance of some five feet of gas per horse power hour was made to cover the extra consumption of oil. A very considerable number of tests of small engines had been made, and although the lowest possible figures approximate somewhat nearly to those given, the average was very much higher, frequently nearer 30 feet than 20.

MR. WIRT also called attention to the fact that the gas engine uses water in considerable quantity. In some cases this expense would be well worth taking into account. Another matter in connection with the gas engine is providing for the exhaust; there must be a large free exhaust, and this exhaust can be led to a point which makes it dangerous in regard to fire, and which makes it necessary to protect it thoroughly.

MR. E. R. WEEKS—I would call on Vice-President Edgar. He has had a very large experience in this matter of motors.

MR. C. L. EDGAR, of Boston, stated that his efforts in the last year and a half to two years had been to sell motor current entirely by meter, that is, selling it by the absolute horse power hour; and of the last 400 horse power which had been used in Boston, 250 are now paying for their current entirely by meter at so much a horse power hour. A nominal charge of 10 cents an hour per horse power is made in making discounts from this down to 40 per cent., so that the minimum rate is 6 cents per hour, the average being between 7 and 8. This is irrespective of the size of the motor. It depends entirely on the number of horse power hours per day as compared with the maximum which that motor can generate. In other words, a one horse power motor might get just as good a rate as a 80 horse power motor, provided it used as much as its maximum, as if it were a larger motor. A man could put in any motor he pleased; he would simply be charged, when he was charged by contract, according to the maximum power which that motor used at any time, as measured by the ampere meter. If a person was going to use 5 horse power and he was inclined to put in a 10 horse power motor, they were very glad to have him do so, and would only charge for the 5 horse power if he used only 5 horse power. He had never heard of a case where a person was charged for 10 horse power merely because he happened to put in a 10 rather than a 5 horse power.

MR. H. M. SWETLAND, of New York, then read a paper entitled, "Standards of Economy in the Generation of Power,"[1] which was followed by an address by Mr. E. F. Williams,[2] of Beloit, Wis., on "Triple Expansion High Speed Engines for Central Station Work."

MR. A. V. GARRATT, of New York, moved, at the conclusion of Mr. Williams' paper, that the subject of Mr. Swetland's paper be referred to the Committee on Data, with the suggestion that if they are not going to make a specific report upon that subject that either a sub committee or a new committee be appointed to report at the next convention on the point touched upon in Mr. Swetland's paper. This was carried.

The report of the Committee on Revision of the Constitution was then called up, and Mr. M. J. Francisco, the chairman, read the proposed new constitution as follows:

CONSTITUTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

Article I.—Name.

This Association shall be entitled the National Electric Light Association.

Article II.—Object.

The object of this Association shall be to foster and protect the interests of those engaged in the commercial production of electricity, for conversion into light, heat or power.

Article III.—Membership.

Section 1.—Members shall be divided into three classes—Active, Associate and Honorary. Active members only shall be entitled to vote and take part in the deliberations of the Convention, and shall be corporations or individuals engaged in the business of producing and supplying electricity for light, heat or power, for commercial or public use.

Sec. 2.—In the case of a corporation, the membership may stand in the name of the company, and such company shall have the right to be represented at any meeting of the Association by any of its officers or directors, or by its regularly employed manager or superintendent.

Sec. 3.—Associate members shall be Electricians, Electrical or Mechanical Engineers, Manufacturers and individuals who are otherwise directly or indirectly interested in advancing the use of electricity, and shall have the right of attending all meetings of the Association except executive sessions.

Sec. 4.—Honorary members shall include those already elected as such, and such other persons as may be elected upon the unanimous recommendation of the Executive Committee and approved by a two-thirds vote of the Association.

Article IV.—Officers and Executive Committee.

Sec. 1.—The officers of the Association shall be a President, two Vice-Presidents, an Executive Committee of nine members, and a Secretary and a Treasurer, who shall be elected as specified in this Constitution.

Sec. 2.—The President and Vice-Presidents shall be elected to serve one year from the first of the month following the date of their election, and shall be active members. The President shall act as Chairman of the Executive Committee during his term of office. He shall not be eligible to re-election for two years after his first term has expired.

Sec. 3.—The Executive Committee shall be chosen from among the active members. The first Executive Committee elected after the adoption of this Constitution shall be divided into three classes. Class one shall serve for the period covered by three Conventions; class two for two Conventions; and class three for one Convention from the first of the month following their election, after which three members of the Committee shall be elected at each Convention to serve for three succeeding Conventions from the first of the month following their election.

1. See page 214.

1. See page 217.
2. See page 222.

Sec. 4.—The offices of Secretary and Treasurer may be filled by the same person. He shall not serve as a member of any committee; shall be eligible for re-appointment and election without limit; shall give a security bond in such sum and with such qualifications as the Executive Committee may determine from time to time, and shall perform such duties as said Committee may direct, subject to their approval.

Sec. 5.—The Secretary and Treasurer shall be nominated by the President and ratified by the Executive Committee. He shall serve for one year from the first of the month following the date of the President's election. He may be an active or associate member.

Sec. 6.—The Executive Committee shall be the governing body of the Association, and shall manage its affairs, pass upon all applications for membership, subject to this Constitution and such special rules or regulations as may be adopted by the Association from time to time, and five members of the Committee shall constitute a quorum.

Article V.—Meetings.

The annual meeting of this Association shall be held in February, and a semi-annual meeting may be held in August of each year, at such places as the Association shall determine, and on such dates as may be determined by the Executive Committee.

Article VI.—Quorum.

Fifteen active members of the Association shall constitute a quorum for the transaction of business.

Article VII.—Dues.

The annual dues of active members shall be twenty-five dollars and associate members twenty dollars, payable in advance, and shall cover the calendar year. Members in arrears for dues shall not exercise the privileges of membership. Any member in arrears for one year's dues shall be dropped from the rolls, and if he is reinstated he will be required to pay his dues for the year in which his membership lapsed.

Article VIII.—Election of Officers.

All officers shall be elected by ballot at the annual meeting of the Association. Vacancies in office may be filled by the Executive Committee to cover the term until the next annual meeting of the Association.

Article IX.—Permanent Office.

A permanent office of the Association shall be established in the city of New York, and shall be located, furnished and governed in such a manner as the Executive Committee may from time to time determine.

Article X.—Parliamentary Rules.

Roberts' Rules of Order shall be the governing parliamentary law of the Association in all cases not definitely provided for by this Constitution.

Article XI.—Voting and Proxies.

Sec. 1.—The roll call shall be ordered on the demand of ten members on any question before the Association. Unless ordered otherwise as specified in this Constitution, all voting shall be by voice.

Sec. 2.—Voting by proxy shall not be allowed at any meeting of the Association or any of its Committees.

Article XII.—Amendments.

Sec. 1.—Amendments to this Constitution shall be presented in writing, and shall be referred to a Committee to be elected by the Association before being acted upon. A two-thirds vote of all members present, entitled to vote, shall be necessary for their adoption.

Sec. 2.—No amendment shall be voted upon by the Convention at which it is introduced.

Mr. M. J. Francisco then moved the following resolution:

Resolved, That the report of the Committee on the Revision of the Constitution be accepted and adopted, and the new Constitution to take effect January 1, 1891.

On motion of Mr. S. A. Duncan, of Pittsburgh, the discussion of the resolution was made the special order of 11 a.m. Thursday. The meeting then adjourned.

THURSDAY, AUG. 21.—MORNING SESSION.

The Association met pursuant to adjournment at 11 a.m.

The proceedings were opened by Prof. J. P. Barrett, of Chicago, who inquired how Mr. M. J. Francisco obtained the figures on the Chicago municipal electric lighting plant, which were contained in his paper on "Municipal Lighting." The question was ruled out of order, as the special business for the hour was the consideration of the report of the Committee on the Revision of the Constitution, which was accordingly taken up. Articles I. and II. were adopted without dissent.

The Secretary then read Article III., to which Mr. A. F. Mason offered the following amendment, so that the section might read:

"Members shall be divided into two classes—Active and Honorary. Active members only shall be entitled to vote, and shall be corporations or individuals engaged in the business of producing and supplying electricity for light, heat or power for commercial or public use."

Mr. Seely—I second it.

The President—The motion has been made and seconded. I presume the gentleman understands the amendment as offered by Mr. Mason; and he will now proceed with his remarks.

Mr. Seely—I call for the reading of that again.

Mr. Mason—Will it be satisfactory if I again read the Article as it would read if it were amended?

The President—Yes; just read it as it would read if the proposed amendment prevails.

Mr. Mason—If my amendment prevails it will leave this section read as follows:

"Members shall be divided into two classes—Active and Honorary. Active members only shall be entitled to vote, and shall be corporations or individuals engaged in the business of producing and supplying electricity for light, heat or power for commercial or public use."

The President—Do the gentlemen all understand it?

Mr. Mason, in explaining the reasons for his amendment, stated that he was compelled in the Committee to say that he could not sign the report, and he had never signed it. He stated to the Committee that it seemed to him that this was, if not a deliberate and intentional, nevertheless a real, insult to every associate member; that it asked him to take a position here which no man could take and maintain his self respect; that it asked him to become a so-called associate member, but with absolutely no rights or privileges excepting those of sitting during the open-door sessions, but not when executive business was being considered—giving him not even the privilege of sitting during those times.

Things had been developed which seemed to render it necessary for the self-protection of the central station members, so that they should have just such a closed door association. He was not one of those who thought so, however.

Mr. T. C. Smith remarked that the associate members were a very valuable part of the Association, and he thought that nothing brought that out more strongly than the fact that in the first place the Association was founded for the benefit of central station men, that they might get information and help from it. In the present state of the industry in this country the central station is absolutely dependent upon the associate member in the manufacturer. There was not, he believed, a single central station in this country that manufactures its own apparatus, wires or its own supplies, except in such minor details as brushes and things of that kind, and there again he was dependent upon the copper men. The time might come when central stations may do, as some of them are now doing in Europe, make their own machinery; but, he thought, that time was pretty far off in this country. Now, when a central station man wished to get information about the merits or demerits of an apparatus or supplies, which he wished to purchase, if he went to another central station man to get his information, the chances would be that he would get an opinion, and that would be all; the material supplied by that man might not be used under the proper conditions, and the conditions intended by the manufacturer, and consequently it was not tried under fair conditions. But if they had associate members at the meetings, and a paper was presented by one of those associate members, or if they got up and made statements, which were not correct, there was sure to be some other associate member in the same line of business who would point out the defects, and the question would be discussed; and the best time for central station men to get the best knowledge, was when the associate members were quarrelling among themselves. (Laughter.) He was of the opinion that at present, the manufacturers were some of the best men in the conventien, men who are not simply salesmen, but who discussed things intelligently and who could meet the central station man on his own ground and make an effort to provide material and devices that should meet his wants; but if the supply men are only to have an opportunity to sell their goods, they would send around a salesman with a big sample case, and that would be the end of it.

He thought that when papers like that of Mr. H. L. Lufkin were received from the associate members, it showed the value of the associate members. A glance through the past proceedings of the Association would show that a great many of such papers have come from such men. He hoped that Mr. Mason's amendment would be voted down. (Applause).

In the ballot for the amendment, the votes of Prof. Barrett, and Messrs. Weeks and Hegeman, were challenged, but on motion admitted.

The amendment was lost by a unanimous vote.

Mr. Alexander then moved to amend Sec. 1 of Art. III to read as follows:

"Section I—Members shall be divided into three classes—Active, Associate and Honorary. Active members only shall be entitled to vote, and shall be corporations or individuals engaged

in the business of producing and supplying electricity for light, heat or power for commercial or public use."

The amendment was adopted.

On motion, Section III of Art. III was made Sec. II.

On motion of Mr. Alexander, the following was accepted by the Committee:

"Section II—Associate members shall be Electricians, Electrical or Mechanical Engineers, Manufacturers, and Corporations and Individuals who are otherwise directly or indirectly interested in advancing the use of electricity, and shall have the right of attending all meetings of the Association except executive sessions, and shall have the right to discuss papers read before the Convention."

MR. WHIPPLE moved the following amendment:

"Section II—Associate members shall be Corporations and Individuals, who are directly or indirectly interested in advancing the use of electricity, and shall have all the rights of active members except the right to vote." This was tabled.

MR. A. C. BROWN—I move to amend Section II. as it now stands, by striking it out and substituting another, which has been suggested to me by Mr. T. C. Martin, of THE ELECTRICAL ENGINEER, and which I now offer. The gist of the change is that, "Members shall be divided into two classes—active and honorary. Active members only shall be entitled to vote and take part in the deliberations of the convention; and shall be corporations or individuals engaged in the business of producing and supplying electricity for light, heat or power for commercial or public use, and electricians, electrical or mechanical engineers, manufacturers and individuals who are otherwise directly or indirectly interested in advancing the use of electricity." Later on, in defining the duty of the President and of the Vice-Presidents, the constitution would be amended to read:

"The President and Vice-Presidents shall be elected to serve one year from the first of the month following the date of their election, and shall be active members. The President shall act as Chairman of the Executive Committee during his term of office. He shall not be eligible to re-election for two years after his first term has expired. The President and Vice-Presidents shall be individuals or officers of corporations actively engaged in the business of producing and supplying electricity for light, heat and power for commercial or public use."

And a new article, as follows:

"*Article XIII. Section I.*—No vote, resolution or declaration of the Association shall stand, or form part of the record, until it has received the signature of the President, who is vested with the power of veto.

Section II.—Any vote may be called up for consideration at the convention succeeding that at which the vetoed measure was introduced, by a two-thirds vote of the members present, and said measure shall only become a valid act of the Association, without the signature of the President, upon then and there receiving an absolute two-thirds vote of the whole membership of the Association."

The amendment was tabled.

Section II. of Article III., as amended above by Mr. Alexander, and accepted by the committee, was then formally adopted, reading as follows:

"Section II.—Associate members shall be electricians, electrical or mechanical engineers, manufacturers, corporations and individuals, who are otherwise directly or indirectly interested in advancing the use of electricity, and shall have the right of attending all meetings of the Association, except executive sessions, and shall have the right to discuss papers before the convention."

On motion of Mr. Wilmerding, Section III, as reported by the Committee, was adopted, as follows:

"Section III.—In the case of a corporation the membership may stand in the name of the company, and such company shall have the right to be represented at any meeting of the Association by any of its officers or directors, or by its regularly employed managers or superintendent."

MR. GARRATT then moved that the following be added to Section IV. (which is Section II. as printed on page 233):

"No individual actively associated with a corporation holding an active membership shall become individually an active member."

MR. E. A. ARMSTRONG pointed out that if this amendment were adopted it would prevent any individual owning a plant supplying electricity for commercial or public use from becoming a member of the Association.

The amendment was lost.

MR. WHIPPLE offered the following amendment:

"Section III—In the case of a corporation the membership shall stand in the name of the company, and such company shall have the right to be represented at any meeting of the Association by any of its officers or directors, or by its regularly employed manager or superintendent, or by a properly accredited representative."

MR. ARMSTRONG—If Mr. Whipple will divide the amendments I will accept the first on behalf of the committee, but not the second. My reason for not accepting the second is this—and I think that he will see the force of the point: That exactly this one thing as suggested by Mr. Mason and by other speakers here can be accomplished by having plants send representatives who are engaged in other business, and not actively engaged in central station business. What we want is not to have the companies send their proxies, but what we want is the men who are actively interested in central station business.

MR. ALEXANDER—There is another reason why that ought not to be adopted. Only yesterday a gentleman told me that he was going to force a certain measure through, and he said that it was merely a question of money. He meant that he could go around to a hundred central stations that have no membership, and say to them, "I will pay your dues, and you can give me your membership." He can do that and then he can come here and rule the whole Association.

MR. WHIPPLE'S amendment was finally tabled.

Sections I, II, III, IV and V of Article IV were then approved.

MR. DECAMP—I would like to offer an amendment to Section VI so that it shall read as follows:

"Section VI—The Executive Committee shall be the governing body of the Association, and shall manage its affairs, pass upon all applications for membership subject to this constitution, and such special rules or regulations as may be adopted by the Association from time to time, and five members of the committee shall constitute a quorum."

He moved to amend by adding, after "membership," the words "and the eligibility of their representatives." Carried.

Articles VI, VII were then adopted.

MR. WHIPPLE—If you will examine Section V of Article IV you will notice a discrepancy between that and Article VIII. Section V of Article IV provides that the Secretary and the Treasurer shall be nominated by the President and ratified by the Executive Committee; whereas, Article VIII provides that all officers shall be elected by ballot. I move to amend Article VIII by inserting after the word "officers" the words "except the Secretary and the Treasurer." This was adopted as amended.

Articles IX, X, XI and XII were adopted.

MR. GARRATT—I would like to present a new article, to be known as Article V., and the subsequent articles to be set ahead one number, so that Article VI. would become Article VII., and so on.

"Article V.—No individual actively associated with a corporation holding active membership shall become an active member individually unless he shall own or operate a central station plant individually." This was adopted.

MR. ARMSTRONG then offered the following resolution:

Resolved, That the report of the Committee on the Revision of the Constitution be accepted and adopted, and that the new Constitution take effect January 1st, 1891. Carried unanimously.

MR. BARRETT—I want to ask Mr. Francisco where he secured the figures with regard to the expenditures in Chicago.

MR. FRANCISCO—In answer to Mr. Barrett's question, I will say that Mr. Barrett is too good a politician, and understands the working of these matters too well to expect that I would disclose the name of the party in Chicago who gave that information. He is inside of that combination, or whatever you call it. The information was given to me from parties who are perfectly reliable; and of course Mr. Barrett knows perfectly well that when such things are given in confidence they are not to be disclosed.

MR. BARRETT—Is not the matter of expenditures in any department of the city government a matter of public record?

MR. FRANCISCO—If Mr. Barrett can read the English language he can see exactly what my paper shows. It gives the wages paid the different men, and the amount charged up for depreciation; and that depreciation I figured myself. The other figures are actual figures as given me as paid for those items. There they are in plain language. There is no chance for misconstruing or evading them. There they are; and I am here to sustain them.

MR. BARRETT—I want to say for the benefit of the Association that there are but two items throughout that statement which are correct; one is the salary of the engineer, and the second is the number of lights. As to the total expenditure as charged by you, there is the slight difference between that and the actual expenditure and what you credit as expenditure, of $35,190. I do not believe that you want to do the City of Chicago, or any one else, an injustice.

MR. FRANCISCO—I did not intend to reflect in any way upon the City of Chicago or upon Mr. Barrett; but it has gone broadcast over the country that it only cost nineteen cents per lamp to furnish light in Chicago.

MR. BARRETT—I just want to say this: That if the balance of that document is in accordance with the statements made for Chicago, then it is the biggest tissue of falsehood that I ever saw published in my life—with all due respect to the Association. I want to ask if you desire to send broadcast the truth about municipal lighting, and if you do, that you will appoint a committee—of whom you will please except this gentleman here, and except him only—and I will pledge you my word of honor that they shall see every document in Chicago, from the date of its inception to the present time; and if it sustains that statement I will

pay the expenses of this committee. I appeal to you, gentlemen, if there is anything more honest or square than that, I want to make it.

MR. ARMSTRONG—Such a statement we would be glad to receive; it will be just the information that we want; and if he would send it to the secretary I have no doubt that the president, or the executive committee, will order it sent to each member of the Association. I move the adoption of the resolution:

After hearing the statement made by Prof. John P. Barrett in relation to the municipal lighting of Chicago,

Resolved, That Professor Barrett be requested to communicate to this Association a statement showing the cost of producing and maintaining electric lights in the city of Chicago.

MR. BARRETT—Let me suggest that it include the cost of construction also.

I want to say with regard to the items of expense that I have to buy the same material as others, and the market is as open to me as it is to others. I am sorry to feel the way I do about this. I have to be as careful of my expenditures as any of you. The people of Chicago are careful of their funds, and we have been short, and we have tried to make a dollar go as far as anybody can do. The market is as open to us as it is to you for the same class of apparatus; and I do not pay any more than the rest of you do.

MR. FRANCISCO—Do you not pay more for labor; and do your men not work eight hours, at $2.00 per day?

MR. BARRETT—The labor only costs more. I do pay $2.00 per day and the men only work eight hours per day.

The resolution of Mr. Armstrong was adopted and Mr. Barrett said he would have the paper ready inside of one month.

Convention then took a recess.

THURSDAY, AUG. 21.—AFTERNOON SESSION.

THE PRESIDENT appointed on the Committee on the Columbian Exposition, P. H. Alexander, Oldtown Electric Light Co., Oldtown, Maine; George H. Roe, San Francisco Electric Light Co., San Francisco; S. J. Hart, Louisiana Electric Light Co., New Orleans, and Mr. Edwards, of the Charleston Electric Light and Power Co., Charleston, S. C.

SECRETARY FOOTE then read the report of the Secretary and Treasurer, as follows:

REPORT OF SECRETARY.

Membership.

Active members, dues paid	79	
Active members, dues unpaid	28	
Total active members		107
Associate members, dues paid	128	
Associate members, dues unpaid	34	
Total associate members		162
Total membership July 1, 1890		269
Total membership January 1, 1890		259
Gain in membership for the six months.		10

REPORT OF TREASURER.

Balance January 1, 1890	$ 610.17	
Received from January 1 to July 1.	3,020.00	
Total to be accounted for		$3,630.17
Expended from January 1 to July 1 per approved vouchers on file	$2,396.57	
Balance in bank July 1, 1890	1,233.60	
Total accounted for		$3,630.17

The report was received and ordered spread upon the minutes.

MR. A. V. GARRATT then read the resolutions of regret relative to the deceased members, Messrs. M. W. Goodyear and Ch. McIntire, which were adopted by a rising vote.

MR. C. R. HUNTLEY then made a short verbal report of the work of the Executive Committee.

THE CHAIR then announced as a Committee on Nominations for Executive Committee, Messrs. T. C. Smith, De Camp, Armstrong, Long and Alexander.

MR. J. A. SEELY, Chairman of the Committee, read the report of that Committee, as follows:

Balance December 31, 1889	$ 610.17
Receipts	3,020.00
Disbursements	2,396.57
Balance June 30, 1890	$1,233.60

The committee recommended that hereafter, whenever a committee is appointed, the executive committee shall fix the maximum amount it will allow for the expenses of such committee and notify its chairman that vouchers for the expenses of his committee will be allowed within the limit specified and no more.

MR. BURLEIGH moved that the report be received and filed and the recommendations carried into effect. Carried.

MR. C. H. WILMERDING then read the report of the Committee on Underground Conduits and Conductors, Joseph E. Lockwood, Chairman.

REPORT OF THE COMMITTEE ON UNDERGROUND CONDUITS AND CONDUCTORS.

At the Kansas City convention, held last February, the following members were appointed a Committee on Underground Conduits and Conductors, viz.:

J. E. Lockwood, of Detroit, Mich.
C. H. Wilmerding, of Chicago, Ill.
S. S. Wheeler, of New York.
T. C. Smith, of Philadelphia, Pa.
D. E. Evans, of Baltimore, Md.

Your committee now desire to report that they have perfected a plan of work, but before carrying out the same desire the opinion of the Association and any suggestion that members especially interested may desire to make.

The plan of work adopted is, first to secure from each electric light or power company operating any high tension, underground conductors a full description of the conduit and conductors in use, the character of the current used, and how long the same has been in use, which information, when classified and tabulated, will indicate plainly the condition of the subject at the present date, and will give us a starting point to work from. We then intend to secure the co-operation of these companies as our next step, which will be to have each company keep account of the cost of maintenance and repairs, to the conduits and conductors, and of all changes or additions thereto; also of the average hours per day the system is operated. This information, when classified and tabulated, will show the cost of operating underground conductors, and, if regularly reported to the committee, will show whether or not progress is being made in this direction, and whether the systems in use are likely to prove permanently successful or to finally fail. It is also designed to include in these reports a list of all grounds, burn outs, etc., and their causes, with suggestions looking to the removing of said causes.

The committee would, of course, keep private the names of all companies furnishing such information, simply reporting the same in tabulated form. These reports would be invaluable to companies operating such conductors, as they would have not only their own experience to improve upon, but also that of all other companies operating underground conductors.

In regard to the details of the plan of work proposed, we have decided on first obtaining the following information, viz.:

Conduits.

1. A full description of the conduit used, kind of man or hand holes, provision for taking off service, etc.
2. Mileage of conduits laid and in use.
3. Mileage of duct laid and in use.
4. Number of man holes.
5. Number of hand holes.
6. Length of time in use.

Conductors.

1. Description of the conductor in use, stating size of conductor, kind and thickness of insulation, and, if insulation is covered, in what manner.
2. How long same has been laid and in use.
3. Mileage of conductors laid and in use.
4. Average hours per diem same is operated.
5. Electro-motive force and character of current used.

The above information would give us a good basis to work on; we would then endeavor to have each company operating high tension underground conductors keep the following records, and report the same regularly to the committee, just before each convention, so that it could be properly classified, tabulated and reported.

Conduits.

Mileage of conduit laid and in use.
Mileage of duct laid and in use.
Number of man holes.
Number of hand holes.
Number of services taken direct from conduit.
Cost of maintenance per month.
Cost of repairs per month.
Description of any new work done since last report.
Troubles with conduit, man or hand holes and suggestions as to how same can be remedied.

Conductors.

Mileage of conductors laid and in use, number of circuits and mileage of each.
Cost of maintenance per month.
Cost of repairs per month.

Number of burn-outs, and causes.
Troubles of other kinds and causes.
Suggestions as to how troubles can be remedied.
Average hours per diem circuits are operated.
Voltage and character of current used.

Changes or New Work.

Mileage of conduit or conductors abandoned.
Mileage of conduit or conductors added since last report.

The above reports would, of course, be separately classified for different kinds of conduits, conductors and currents.

Your committee think that these records should be kept continuously and reported regularly, until the question of operating high tension underground conductors is solved or effectually disposed of, and to do this we recommend that the committee be made permanent, and that members be elected annually at the February conventions.

The committee should report at each convention:

The number of companies operating high tension underground conductors.

The mileage of conduits, ducts and conductors in use.

The cost per mile per month of conduit maintenance and repairs.

The cost per mile per month of conductor maintenance and repairs.

The average number of burnouts and grounds per mile of conductors used and the causes. It should also report all conduits, conductors, etc., that had proved failures and were abandoned.

In this manner the Association would keep thoroughly posted regarding the progress of the subject, and would be supplied with the actual records made by the different systems; the members of the Association could then judge for themselves of the success of the different systems, and thus be able to act intelligently in case they desired to do any work in this line.

As this plan is intended to extend beyond the time for which this committee was selected, we have recommended that the same be adopted by the Association and that provision be made for the annual appointment of members to the committee. If this meets the approval of the convention, we would appreciate any suggestion from members who are especially interested in this subject, looking to the perfecting of the plan of work.

MR. WILMERDING added that in his opinion one point had been omitted in regard to the cost of the conduit that is down. That cut a very important figure in the estimate of what it really means to operate underground conductors, and thought the Committee ought to have the privilege of adding any such questions to their catechism which they will submit to the companies using underground work, which they thought might be necessary.

The report was adopted.

The report of the Committee on Relations between Manufacturing and Central Station Companies was then read by Judge E. A. Armstrong, a member of the Committee.

REPORT ON THE RELATIONS BETWEEN MANUFACTURING AND CENTRAL STATION COMPANIES.

The vast sums of money now invested as capital in the United States in the various electric light and power companies make the subject with which this Committee has to deal more than ordinarily important.

From every point of view the policy that has been more or less surreptitiously pursued by parent companies in *permitting* their agencies, for the sake of a present sale of apparatus, to foster and encourage improper and hurtful competition with present central station companies, cannot in our judgment be too strongly condemned by this Association.

Capital has been induced, in spite of its proverbial timidity, to invest in what has been an unexplored field. Often this investment has been brought about by the parent companies themselves. Then when it has seemed as if the stormy days of doubtful experiment were about over, and there was some little possibility that this investment might begin to make returns, along comes the agent of some parent company and by specious representations induces other citizens of the same place to start a new plant, always forgetting to tell of the weary journey of the pioneer company, and pointing always to present position. The only province of this new plant is to damage and destroy what did give some promise of life and fruit; and incidentally to make a market for a little new apparatus, effectually closing, however, a profitable avenue of steady continuing business in sales to the original companies.

It is rumored very strongly, and indeed stated as a fact, strange as it may seem, that parent companies, not satisfied with permitting, have gone so far as to actually organize, central station companies in competition with others which are abundantly able to supply all demand, strengthening, supporting and sustaining them in their unholy warfare against legitimate enterprise.

Such being the case, your Committee would earnestly recommend either its continuance or the appointment of a new Committee with power to confer and advise with any companies against whom such warfare is waged, and that through such committee the members of this Association as central station companies, pledge sympathy, assistance and protection to any company so being fought; and that such committee be instructed to represent to the various parent companies that the conduct we have above deprecated is something so fatally injurious to us and to our stock holders as to make our investments uncertain and undesirable, and that, therefore, we will as one Association feel not only justified in, but required to take the strongest possible means of remedy and prevention within our power, whenever we find a parent company engaging in, or permitting, such a course of conduct. When it has already been started, any such company so minded can readily stop it.

The report of the Committee was received and the Committee continued.

The Committee on Data, A. J. De Camp, Chairman, reported progress.

THE PRESIDENT then announced the topic, "How the National Electric Light Association can Best Serve the Interests of Central Station Companies?" by Mr. C. R. Huntley.

MR. HUNTLEY—I think that this topic might be discussed upon another heading, and better still, viz., How can the Central Station Men Best Serve the National Electric Light Association? As we look about us to-day here we see perhaps thirty-five or forty central station people; in fact they are in the minority. We find a great many supply men here taking an active part in it; but conspicuously the central station men are not as active in their membership or in respect to their pocket book to aid the National Electric Light Association as they might be. I think, to put the whole matter in a nut-shell, that the National Electric Light Association should be purely a business association, and in being that they will best serve the central station men.

THE REPORT of the committee to nominate an Executive Committee for the ensuing six months and to name a place of meeting was then read, unanimously recommending as the next place of meeting, Providence, R. I., the time to be announced hereafter by the Executive Committee. The committee also unanimously concluded that it is only due to the Executive Committee, and to the work which they have so thoroughly done, to continue that committee, the only change made being the substitution of Mr. A. J. DeCamp for Mr. Thurber, by request. The report was adopted.

SECRETARY FOOTE cast the ballot for the Executive Committee as follows: C. R. Huntley, Chairman; E. R. Weeks, C. H. Wilmerding, J. J. Burleigh, M. J. Francisco, J. A. Seely, James English, A. F. Mason, A. J. DeCamp.

On motion, Providence, R. I., was made the next meeting place of the Association.

The convention then adjourned *sine die*.

THE ELECTRICAL EXHIBITS AT CAPE MAY.

FOLLOWING the example of past years the various electrical supply houses took to Cape May this year most interesting exhibits of all the novelties which have been introduced to the trade this year. Every available parlor on the ground floor, and space in the large hall of the Hotel Stockton, was utilized for the purpose of showing exhibits, and though there was no power available, the showing was a very good one.

CROCKER-WHEELER MOTOR CO.

Entering at the main entrance of the hotel, the first exhibit that attracted notice was that of the Crocker-Wheeler Motor Company, of New York, represented by Messrs. F. B. Crocker, S. S. Wheeler, and T. McCoubray. On one end of their table, which was well decorated with a frame and canopy, and their name in large letters, was a 1-6th horse power motor, belted to a pump manufactured by the Gould's Manufacturing Company, of Seneca Falls, N. Y. This motor is capable of furnishing sufficient power to enable the pump to lift 100 gallons of water per hour 80 feet, equal to a pressure of about 40 pounds. On the other end of the table was a 1-2 horse power motor, geared direct, and sitting on the same cast-iron frame with another form of Gould pump. In the centre of the table was a 1 horse power motor of the slow speed type, making only 1,030 revolutions per minute. There were also a number of small motors for fan and other purposes, and the method which they adopt of fixing on the guard frame of the fan is worthy of mention, as being peculiarly substantial, and it is easily put on and taken off. There was also exhibited an arc motor and one of the pulleys which are used on this motor, showing the centrifugal governor contained inside, by means of which the armature is moved in and out of the field. The rheostat for controlling the motor was also shown. It is so arranged that the field is cut in before the armature, in starting up the motor, and is cut out last in stopping, so that there is no violent motion in starting or stopping. The pulleys on the small motors are also worthy of mention, being exactly like ordinary iron dynamo pulleys, with flanges, though very small. We present herewith a fine chromo-lithographic print of the motor. (See supplemental inset.)

ELECTRICAL SUPPLY CO., OF CHICAGO.

Adjoining the exhibit of the Crocker-Wheeler Company was a table occupied by the Electrical Supply Company, of Chicago, and Ansonia. They did not make any exhibit this season, but had a large supply of interesting catalogues and circulars. Suspended over the table they showed the latest specialty, the Bradner Adjustable Lamp Hanger, by which lamps can be suspended at any desired height by merely moving the hanger up or down, the slack of the cord being all taken up inside the hanger, which is spherical in form to contain the lamp cord. The Electrical Supply Company, was ably represented by Mr. Charles Wirt, of Chicago, and Mr. F. B. Platt, of Ansonia.

UNITED ELECTRIC EQUIPMENT CO.

Continuing along the main hall, the only other exhibit in this part of the building was that of the United Electrical Equipment Company, 706 Walnut street, Philadelphia, who are agents for the Wenstrom Consolidated Dynamo and Motor Co., the George M. Stevens system of town and city fire alarm, and the American Fire Alarm Company, of No. 71 Kilby street, Boston. They exhibited one of their well known Wenstrom dynamos, of 32 light capacity, and had the armature out, so as to show the peculiar construction. The armature is composed of laminated iron discs, but the wire, instead of passing around the outside of the cylindrical mass of iron plates, is threaded through holes in the rims of the discs. The whole armature is then turned down, and there being no wires on the surface, the armature can be made to fit very snugly in the field. They exhibited also samples of the special gears of Chadbourne, Hazleton & Company, recently illustrated in the columns of THE ELECTRICAL ENGINEER. These gears are composed of metal frames with wooden teeth, which can readily be replaced when worn out. A very neat exhibit shown by this company, and one which attracted a good deal of attention, was the model of a complete electric elevator plant, driven by a small Wenstrom motor. The carriage carrying the grooved pulleys is operated by a screw shaft, cut with a right and left hand thread. When hoisting, the pulleys are thus separated from one another and thus pull in the rope which goes to the elevator. When lowering, the pulleys are brought closer together, by the screw shaft revolving in the opposite direction, the motor operating the shaft being reversible. This company also exhibited a very complete set of instruments of the automatic fire alarm system of the American Fire Alarm Company, and had the instruments connected by auxiliary boxes of the George M. Stevens city fire alarm system, which were temporarily connected to the fire department of Cape May. A fire alarm bell had been erected in the pagoda in front of the hotel, and the guests of the hotel were treated to an exhibition of the automatic fire alarm, by which the fire department turned out to extinguish a supposed fire in the Stockton Hotel. The experiment was successful in a very striking manner. Mr. Chas. Russell, of Philadelphia, and Mr. E. F. Woodman, of Boston, were in charge of the exhibit. They had a very complete set of blue prints, illustrating their motors as applied to elevators, street car work, mining machinery and various other purposes.

INTERIOR CONDUIT AND INSULATION CO.

Passing down through the ladies' parlor towards the dining room, the Interior Conduit and Insulation Company, of New York, occupied a very commodious parlor and showed up their specialties in conduits both for house and underground work. Samples of their tubes and junction boxes were exhibited on a very handsome polished mahogany board, extending all the way across the room. The tubes are generally made black for ordinary concealed work, but they can be enameled in any color to correspond with any style of decoration for exposed work. The junction boxes can now be made of any material and decorated beautifully, and really form an ornamentation to the most elegantly furnished room. Some of the samples shown were particularly attractive in design, bearing medallion portraits of Morse, Edison, Faraday and Faure. A sample of their underground conduit was also shown, models being exhibited, one of the conduit complete and the other made to open up, exposing the tubes resting on insulating rings before the compound is poured in. There were also hung on the walls a most interesting collection of blue prints, showing the design of the manholes for the underground system, which have some novel features. The conduit, instead of entering the manhole horizontally in the ordinary way, enters in an upward slope, the top of the conduit coming near the top of the manhole, enabling the cables to be easily drawn in without using any winch or other apparatus in the manhole. Joints can also be more conveniently made, and the cables can then be covered up by an insulating sleeve. The Interior Conduit Company distributed a very handsome pamphlet of testimonials, containing letters of endorsement from all of the leading electricians of the day. The exhibit was in charge of Mr. E. H. Johnson, the president of the company, ably assisted by Mr. E. W. Little and Mr. Edwin T. Greenfield.

THE JORDAN TROLLEY WIRE SUPPORT.

IN erecting trolley wires for electric railways the custom is generally followed of soldering the wire to a metallic support. This operation is attended with considerable inconvenience. At the same time the span wires supporting the trolley wire are usually made with joints at the centre over the trolley wire, instead of in one piece, and hence introduce a source of weakness at that point. To remove both these inconveniences, Messrs. L. F. Jordan & Co., of Boston, Mass., have recently brought out the trolley wire support illustrated in the accompanying engraving.

THE JORDAN TROLLEY WIRE SUPPORT.

The hanger or support consists of two pieces or jaws, each provided with lugs, which extend under and support the trolley-wire when the jaws are screwed together. The jaw is provided at its opposite ends with lugs, between which and the ear of the jaw the trolley-wire is extended, the lugs preventing the trolley-wire from being lifted upward.

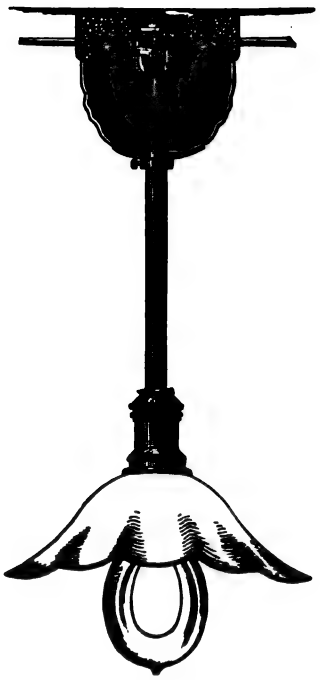
The support is provided, as shown, with an upright arm, having at its end a hook, which is fitted upon the hub of an insulating disc, both being provided with a slot by which the disc can be placed upon the span-wire. The hub of the disc, as shown, has also mounted upon it a like slotted disc, these discs being provided on their outer side with extended hubs, which are fastened to the span-wire by clamps.

In erecting, the set-screws are unscrewed, so as to permit the discs to be turned so that the slots will register with the slot of the hook, so that the hanger may be readily slipped upon the span-wire; then the discs are turned so as to bring their slots out of line with the slot of the hook, and secured in that position by the clamps. It will thus be seen that the hanger is insulated from the span-wire and has a pivotal movement upon the same.

The trolley-wire is thus firmly clamped between the jaws of the hanger, and is secured positively without the use of solder, and is prevented from falling at the points of suspension. The guy-wire is also endless, so that there is no weak spot in it. The device was exhibited at the Cape May Convention.

THE BRYANT ELECTRIC COMPANY.

In the same hall was an exhibit tastefully designed by the Bryant Electric Company, of Bridgeport, Conn., displaying the famous Bryant switches, rosettes, lamp sockets, Orford pendant rosette and other specialties. The Bryant Company have now got thoroughly reorganized and are in the market for a large business, and have a large number of men at work in their new factory at Bridgeport. They were ably represented by Mr. W. C. Bryant and Mr. J. M. Orford. The Bryant switch was illustrated in THE ELECTRICAL ENGINEER last week. The Orford pendant is shown herewith. It is a neat and handy contrivance, allowing the pendant play and swing on the hook in such a manner as to prevent all possibility of disconnection or dislocation, and preventing the occurrence of fires by abrasion of insulation or loose contacts.



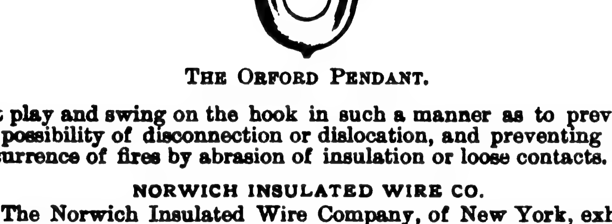
THE ORFORD PENDANT.

NORWICH INSULATED WIRE CO.

The Norwich Insulated Wire Company, of New York, exhibited a large and varied assortment of samples of their insulated wires and cables, and were represented by Mr. L. D. Beck, president of the company, and Mr. J. A. Wetmore. These wires are insulated with manilla paper wound spirally on, and then treated with a heavy gummy oil, which parchmentizes the paper, and is then lead covered. Paper when dry offers an extremely high insulation resistance. As a sample of the high value of this insulation, two samples were shown, each cut from a 1,300 foot length, one covered with the paper and lead covered, without being treated with the compound, which took 9,120 volts alternating current to break down the insulation. The other, a thoroughly finished cable, successfully withstood 9,440 volts alternating current, and could not be broken down. It is interesting to note that Ferranti, in London, is now experimenting with these cables for his 10,000 volt circuits, and up to the present time is thoroughly satisfied with them.

STAR ELECTRIX CO.

The Star Electrix Company, of 1320 Wallace street, Philadelphia, represented by Mr. Norman Marshall, president and manager of the company, showed some samples of single and double pole switches, insulating joints for coupling and insulating gas fixtures, and an insulating attachment for fixing incandescent lamps to ordinary gas fixtures, which can be made in brass or any other colored metal, as desired. The attachment is illustrated on this page.



STAR ELECTRIX INSULATING ATTACHMENTS.

EUREKA TEMPERED COPPER CO.

In the same hall with the Sawyer-Man Co., the Eureka Tempered Copper Co., of North East, Pa., had an interesting exhibit of copper castings made out of absolutely pure copper, and tempered by their patent process to any desired gauge. In their exhibit were shown samples of commutator segments, dynamo brushes, rolled copper for brushes, spring rolled copper, journal bearings, and copper castings of various kinds. The Eureka Company claim that they can now temper copper to a razor edge, if necessary, and yet at the same time it can be welded perfectly, and Mr. A. L. Daniels, their representative at the convention, distributed a number of pamphlets, setting forth their many claims for the use of tempered copper for all electrical work.

WARNER ELECTRIC LIGHT GAUGE.

IN electric light stations operating arc lights it is of considerable importance to keep the current on the circuits constant, and notwithstanding the regulating apparatus, some indicator is required to allow the attendant to watch the condition of the circuit. To accomplish this the Warner electric light gauge has been designed by the Standard Time Co., of New Haven, Conn., and which is illustrated in the accompanying engraving. The electric gauge resembles the ordinary steam gauge and has a large dial about 6 inches in diameter, which can be easily seen at a distance.

The arrangement is such that when the current at which the circuit is designed to operate is normal, the pointer stands at zero. The figures "above" and "below" represent the variations in amperes above or below the normal strength. Thus, if the pointer stands at 1 above, the current flowing would be 11 amperes, and if at 1 below, 9 amperes.

THE WARNER ELECTRIC LIGHT GAUGE.

The small pointer shown through the opening in the dial will point in the direction that the current is flowing, which indicates the negative binding post.

The gauge is furnished with an alarm attachment which may be set to ring when the pointer is at any point desired, above or below the normal, thus calling the engineer's attention when anything is wrong.

This gauge was exhibited by Mr. Warner at the Cape May Convention, where he also showed the ingenious pocket and office gauges for testing the condition of batteries. For secondary battery work the pocket size ranges from 1 to 3 volts and indicates $\frac{1}{10}$ volt with accuracy. The office gauge is intended as a fixture in the battery room with leading wires that can be applied to the terminals of any cell, so that its condition can be readily determined.

Mr. Warner also exhibited his fire alarm gauge, intended to be placed in fire alarm circuits to indicate continuously the condition of the line current.

CONNECTICUT MOTOR CO.

The Connecticut Motor Company, of Plantsville, Conn., exhibited a very handsome ½ horse power motor, which attracted much attention, and received universal praise for its high finish and neat appearance This company is now furnishing a number of motors for ventilating fans in government boats, and is just preparing for a very heavy business in the fall. Mr. J. R. Stagg and Mr. Roberts had charge of the exhibit.

EVANS FRICTION CONE CO.

The Evans Friction Cone Company, of Boston, were represented by Mr. H. J. Conant, and had no special exhibit, but distributed large numbers of catalogues, and blue prints showing in detail their system of driving dynamos by the Evans friction pulleys. The company are now engaged on a number of central station plants, and their system is being widely adopted, on account of its economy, compactness and durability.

SAWYER-MAN ELECTRIC CO.

Coming back to the side-hall on the left of the entrance the Sawyer-Man Electric Company, of New York, had an interesting display of their various electric specialties. On the wall was a large case containing samples of their different varieties of lamps for straight incandescent and series incandescent lighting. The series lamp is mounted on a socket containing an automatic cut-out with resistance to replace the lamp should the filament break or burn out. All the exposed parts are made of insulating material. On the table in the centre of the room were exhibited the new branch cut-outs made of porcelain, their regular form of single and double pole switches, cut-outs, rosettes, sockets, detachable plugs, Field's mercury cut-out and other specialties. Probably the most interesting feature of their exhibit was the new insulating material which the Sawyer-Man Company are introducing, and which they have named "Alexite." This material is fire-proof, water-proof and acid-proof, not fragile, highly durable, and can be moulded into any desired shape; but the most marvellous quality it possesses is the infinite variety of shades and colors it can be made to assume. A neat manner of showing how closely different colors of wood and marble could be imitated was adopted by having samples of all the known woods generally used in decorating rooms, on the table, with sample of marble and other polished stones, and on top of each sample was placed a sample of "Alexite," so closely imitating it, that the difference could hardly be noticed. For the manufacture of cut-outs, fuse boxes, rosettes, etc., this material lends itself naturally, and its property of being able to take on any desired finish must commend itself to electrical contractors, especially for exposed work in houses where something better and more ornamental than ordinary is required. Mr. P. H. Alexander and Mr. Morris, of New York, had care of this exhibit.

JORDAN TRAIN LIGHTING CO.

The Jordan Train Lighting Company exhibited samples of their electric light coupling for joining cars together, so that the current from one car can pass conveniently into the other. The coupling has only to be pushed closely together to form the connection, and it can be pulled out at any moment. The whole coupling and connecting wires are thoroughly water-proof. They also exhibited samples of their new trolley line suspender, which does away with any necessity for soldering, and which is meeting with well merited success.

INDURATED FIBRE CO.

The Indurated Fibre Company, with headquarters at 40 Wall street, exhibited samples of their indurated fibre pipe for underground conduits, showing straight pipe, joints, and junction boxes. A sample of the pipe was also shown, made out of the fibre before being treated with the compound, displaying the close nature of the fibre. They also exhibited samples of pails and other goods, specially a keg which they have designed especially for containing powder. The lid is screwed on, making a hermetically sealed keg. The conflict on the patents of this material is now settled; this company have control of all the patents, and have capitalized two companies at $1,000,000 to push their goods, one for electrical purposes, and the other for all mechanical purposes. The material weighs only one-fifth of iron pipe, has a tensile strength of 1,100 pounds to the square inch, resists about 250 degrees of heat, and is perfectly water and gas tight. The exhibit was in charge of Mr. G. S. Bowen.

WASHBURN & MOEN MANUFACTURING CO.

Washburn & Moen Manufacturing Company, of Worcester, represented by Mr. H. M. Smith, exhibited a handsome case containing a complete line of samples of bare and insulated copper wires, soft and hard drawn, solid and stranded. They also showed a sample of 2¾ inch stranded bridge cable, and Mr. Smith distributed a little pamphlet, entitled "Electrical Memoranda," which was in great demand, giving a historical account of electrical events, showing the close connection with the great and ever increasing demand for copper, and containing a variety of useful data.

AMERICAN WALTHAM WATCH CO.

The American Waltham Watch Company were ably represented by Mr. H. E. Duncan, of Boston, who exhibited no samples, but spent his time largely in the exchange of social courtesies with a host of friends.

R. T. WHITE.

Mr. R. T. White, of 12 Pearl street, Boston, exhibited a number of his patent chairs for supporting railroad metals for electric railroads, and which are being largely adopted all over the country for first-class electric railways.

EDDY ELECTRIC MOTOR CO.

The Eddy Electric Motor Company, of Windsor, Conn., was ably represented by our popular friends, Mr. A. D. Newton and Mr. M. E. Baird, but exhibited no samples, their motor being so well known now that they evidently required no representation, other than personal.

SEELY'S FLEXIBLE WIRED MOULDING.

It is safe to say that few of the exhibits attracted so much attention as Mr. J. A. Seely's new "flexible wired moulding." As our readers are aware, the whole subject of interior wiring has of late been most vigorously and thoroughly stirred up, and departures revolutionary and radical in their nature have been made, to such a remarkable extent that we have really entered upon a new era in this important field of work. Mr. Seely's ingenuity and versatility have long been tried and proved in the whole round of electrical application, and hence it is not surprising that he should come forward with a means of his own for meeting the obvious and serious difficulties of wiring work. The device or appliance is not exactly new, as we had the pleasure of being shown it by its inventor some months ago, but it is now to be actively pushed, and its novelty at once appeals to the electrical public. Mr. Seely has hit upon the ingenious idea of making his moulding out of rubber, and in this moulding at the same time he imbeds his wire. In other words, he wires his moulding before he puts it up, or, to state it another way, he insulates his wire with rubber moulding and then puts it up. This flexible wired moulding is made in all the various sizes of wire ranging from No. 16 to No. 0, and comes in any length required. It shows under test the high insulation of 500 megohms between the positive and negative conductor sides. The moulding corresponds, of course, to ordinary wooden moulding and answers exactly the same conditions, as well as having a number of advantages distinctively its own. It can be placed on ornamental ceilings and walls without defacing them, and will take any decorative finish required. It is also peculiarly applicable in old houses and buildings where it is impossible to get behind the walls or to bury the wires in the plaster. It can be handled in rolls of several yards, cut to any needed length, and carried right to the spot, with the consequent avoidance of expensive carting, and the cutting, sawing, etc. Not a few customers for the light object very emphatically to the sawing and cutting on their premises. The Seely & Taylor Manufacturing Co., who are introducing this specialty and exhibited it at Cape May, have worked out also a full line of branch blocks, tees, etc., together with a special form for the purposes of turning right angles and taking off branch circuits. It is claimed that a saving of not less than 40 per cent. is made over the old methods, and this alone is enough to ensure an enormous demand. A singular instance of appreciation was afforded a week or two ago when, the moulding having been used by one local company in a large city, another competing local company ordered a large quantity, saying it was an absolute necessity and it could not afford to try to do without it.

The moulding, it should be added, is also handled by the Okonite Co., who are its manufacturers for the Seely & Taylor Manufacturing Co., and who have lately put in a large plant for its production. Under such favorable circumstances, it is expected that the moulding will at once go into use everywhere.

THE OKONITE COMPANY, OF NEW YORK.

The Okonite Company occupied a comfortable parlor on the ground floor, and Capt. W. L. Candee and Mr. George T. Manson, of New York, looked after the interests of their numerous friends. Handsome photographs of different rooms in their new factory at Passaic, N. J., decorated the walls, and on the table were displayed a complete assortment of samples of their Okonite cables, tapes, wires and flexible cords. They also showed samples of the Seely flexible moulding, which they manufacture in large quantities.

SPERRY ELECTRIC CO.

The Sperry Electric Co., of Chicago, exhibited on one of the poles of the local lighting company, in front of the Hotel Stockton, probably the greatest novelty at the convention, namely, their new Triple Carbon Arc Lamp, specially designed to avoid the broad patent, held by the Brush Electric Company, on double carbon lamps. The triple carbon holders can be attached to any of their ordinary single or double carbon lamps. There are two upper cylindrical carbons, and a lower flat one, and it is stated that by this arrangement the lamp will burn for 16 to 18 hours. The exhibit was in charge of Mr. Charles E. Gregory, who also showed drawings of mining machinery.

NEW YORK INSULATED WIRE CO.

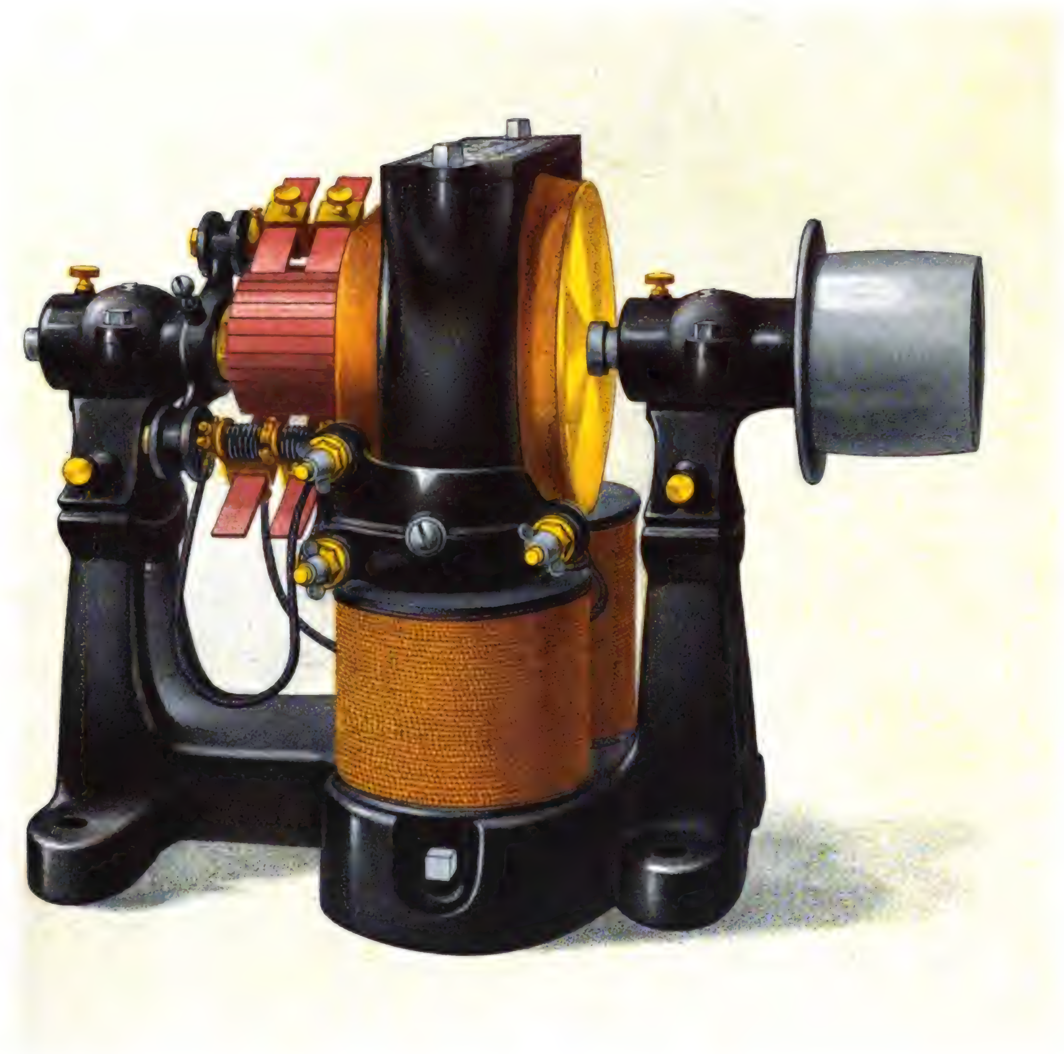
The New York Insulated Wire Company had a full line of samples of their excellent cables, tapes and wires, and were represented by Mr. C. A. Place, Mr. R. E. Gallaher, G. H. Meeker, and J. W. Godfrey, who took care of the delegates in their usual hospitable manner.

STANDARD UNDERGROUND CABLE CO.

The Standard Underground Cable Company, of Pittsburgh, were well represented by Mr. J. W. Marsh, of Pittsburgh, Mr. George L. Wiley, of New York, and Mr. F. E. Degenhart, of Chicago. Such a trio of good fellows could not fail to impress the members, even though they made no attempt to exhibit their cables and wires.

JOHN A. ROEBLING'S SONS.

John A. Roebling's Sons, of Trenton, N. J., did not make any exhibit, but were well represented in the persons of Mr. W. L. Shippey, Mr. W. E. Frick, and Mr. F. A. C. Perrine, who managed to make themselves seen and heard on all sides.



THE CROCKER-WHEELER
PERFECTED ELECTRIC MOTOR.

CONSOLIDATED ELECTRIC STORAGE CO.

The Consolidated Electric Storage Company had an attractive exhibit of their improved storage batteries in a neat oaken case, containing twelve cells. The case was mounted on an oaken table, on which were set a volt meter, ammeter and switch for measuring and manipulating the current. The cells were shown in operation, furnishing current for three 24-volt incandescent lamps, and a small motor. The Chamberlain connector, recently illustrated in the columns of THE ELECTRICAL ENGINEER, was exhibited in use, and the cells were not re-charged throughout the three days, though in constant service. Mr. Wm. Bracken, Mr. P. G. Salom, and Mr. F. H. Deacon represented the Consolidated Company at Cape May.

SIMPLEX ELECTRICAL CO.

The Simplex Electrical Company, of Boston, showed no samples of their wires, but were represented well in the person of Dr. A. F. Mason, the popular general manager of the company; also by Mr. W. H. Gordon, of W. H. Gordon & Co., and Mr. George Cutter, of the Great Western Electric Supply Company.

NEW HAVEN ELECTRIC WIRE CO.

The New Haven Electric Wire Company, of New Haven, Conn., were represented by Mr. C. I. Hague, who did nobly to keep up the reputation of his house, though he made no particular exhibit, saving a few samples of their Helmet Brand wire, which is sold largely through the Empire City Electric Company, of New York.

A. G. DAY'S KERITE.

The old standard insulation, "Kerite," was ably represented at the convention, by Mr. Geo. B. Prescott, Jr., who did not make a large display, but contented himself with the exhibition of a few samples of wires and cables, and the distribution of their new illustrated catalogue and price list.

EDISON GENERAL ELECTRIC CO.

The Edison General Electric Company, of New York, had no exhibit, but were represented by Mr. H. Ward Leonard, Mr. W. H. Fleming, and Mr. J. F. Kelly, the former looking after the general lighting interests, while the latter paid attention to wires and cables.

LEWISOHN BROS.

Lewissohn Brothers, of New York, dealers in copper wire and all kinds of copper goods, were ably represented by our genial and popular friend, Mr. Sam Rosenstamm, of New York, who always contrives to look cool and happy, and shed a cheery ray around him.

THE PERRET MOTORS.

The Elektron Manufacturing Company, of Brooklyn, exhibited one of their well-known and widely used Perret motors, which attracted much attention by its excellence of design and high finish of workmanship. The company also distributed their new pamphlet, in which they discuss the question of low speed, showing how desirable low speed is in dynamos and motors, and illustrating the principles by their own successful practice.

THE NATIONAL CARBON CO.

IN accordance with their excellent custom, the National Carbon Co., of Cleveland, O., represented by Messrs. Crouse, Miles and Smith, distributed copies of their "Directory of Electric Arc Lighting Plants." The new issue, brought down to date of August 1, s a publication of over 100 pages, and in spite of the many difficulties attendant on the task, exhibits every sign of care, completeness and accuracy. The Directory goes by States, and each town and city is given, with its local company or companies, and the name of the system used. The lights are divided into commercial and street lamps, and the total is also given. The list of private or isolated plants is also thorough, and thus one is able to see at a glance just how many arc lights are in use in any one town and to figure on the demand for supplies or the prospects of increasing the local capacity. The National Carbon Co. are well known throughout North and South America as makers of carbons, and are supplying Brush, Thomson-Houston, Western Electric, American, Ball, Reliance, Schuyler, Sperry, Wood, Excelsior, United States, Fort Wayne and other plants with their molded and forced carbons. They are now also developing a large trade in carbon brushes for dynamos and motors, and in carbon plates and shapes for every class of electrical work.

JEWELL BELTING COMPANY.

Mr. C. L. Tolles, on behalf of the Jewell Belting Co., of Hartford, Conn., exhibited in his rooms a number of fine specimens of their belting, of the kind in use in a number of electric light plants.

PASS & SEYMOUR.

The above concern were represented by Mr. Seymour, himself a central station man and familiar with the requirements of the work. They have gone into the production of electrical chinaware at Syracuse, N. Y., and the productions shown are certainly such as to secure for them a large share of business. Their goods show the signs of thorough vitrification, and are of great strength, fine color and exquisite finish. Their plant is specially designed for this class of work, and their machine shop is fully equipped for die making, so that in these and other electrical novelties, a line of which they are now getting together, they bid fair to build up a large trade.

THE WESTERN POWER CONSTRUCTION CO.

One of the leading Western visitors to the convention was Mr. W. P. Adams, the general manager of the Western Power Construction Co., of the Rookery, Chicago, which has lately been cutting such a wide swathe in the equipment of electric light and power plants. The company represent the McIntosh & Seymour engines in a large territory, and since their recent organization have done an enormous business.

ABENDROTH & ROOT MANUFACTURING CO.

The above company, of 28 Cliff street, this city, were admirably represented by their very handsome pamphlet, in which are set forth the various features of their well-known water tube Root boilers. This pamphlet, replete with illustrations and descriptive text, was accompanied by two others on the same subject, one giving the sizes and dimensions and the other giving a partial list of some of the firms using the boilers.

CONVENTION NOTES.

JAMES W. QUEEN & COMPANY made an interesting exhibit of their high class instruments, including galvanometers, resistance boxes, testing sets. A portable photometer and a resistance box of one megohm attracted considerable attention.

THE BRADY MAST ARM COMPANY, of New Britain, Conn, were represented by Mr. T. W. Brady, who is well known as a reliable manufacturer of mast arms, lamp hoods, etc.

THE NATIONAL CONDUIT MANUFACTURING COMPANY had Mr. J. P. McQuade, of New York, looking after their interests.

THE D. M. STEWARD MANUFACTURING COMPANY, of Chattanooga, Tenn., manufacturers of lava electric insulators, and insulating material for all electric purposes, were represented by Mr. D. M. Steward, the president of the company. The business of this company is increasing very rapidly, and they are making large additions to their productive facilities.

THE EASTERN ELECTRIC CABLE COMPANY, of Boston, were represented by Mr. H. H. Eustis, of Boston. No exhibit was made.

PETTINGELL, ANDREWS COMPANY, Boston, were represented by Mr. F. E. Pettingill, who is just as energetic as ever, and as well informed on every new development of the business.

THE ELECTRIC GAS LIGHTING COMPANY, of Boston, had no exhibit but had their indefatigable general manager, Col. Louis W. Burnham, on the ground to meet his friends, whose name is legion. Col. Burnham has always a "battery" of good humor at his disposal, as inexhaustible as the "Samson," and manages to enjoy himself and make others enjoy themselves wherever he goes.

THE E. S. GREELEY COMPANY did not make any exhibit, but sent Mr. Frank A. Magee to look after their interests, which he did with his usual good nature and thoroughness.

CHAS. A. SCHIEREN & COMPANY were represented by Mr. G. H. Fisher and Mr. E. P. Atkinson, who discussed the merits of Schieren belting.

THE MOORE & WHITE COMPANY, of Philadelphia, Pa., manufacturers of Friction Clutch Pulleys, Cut-off Couplings, etc., were represented by W. H. Shoemaker, who also looked after the interests of the Main Belting Company, of Philadelphia, manufacturers of the Leviathan Belting.

THE CROSBY ELECTRIC CO. made an exhibit of the new dry battery they control, recently brought out by Mr. J. H. Van Gestel, who was himself present to describe its features and merits.

THE STANDARD PAINT CO. made an exhibit in a quiet way of their P. & B. paints, insulating compounds, varnish for armatures, etc., insulating papers and other specialties. They were represented by President Ralph Shainwald and Mr. W. W. Castle.

THE CONSOLIDATED FRUIT JAR CO. was represented by Mr. F. P. Wisner. The company is making a specialty of fuse wire, and a number of metallic parts required in electrical work.

THE PUMPELLY STORAGE BATTERY CO. distributed a neat little pamphlet, giving information as to their storage batteries, now being used quite extensively in electric light work.

THE WALSH GASOLINE TORCH CO., of Chicago, distributed a quantity of reading matter in regard to their torch for linemen, the features of which were described in a recent number of THE ELECTRICAY ENGINEER.

WM. BARAGWANATH & SON, the well-known builders of steam apparatus at Chicago, distributed illustrations of their feedwater heaters, purifiers, boilers, &c.

THE CHICAGO FIRE-PROOFING CO. exhibited samples of its mineral wool insulation for covering steam pipes and boilers, and the data in regard to same was set forth in print for general circulation.

THE NUBIAN IRON ENAMEL CO. has found a market for its specialty in the electrical field, as a coating for arc lamps; and on this occasion it issued a fac simile of the letter from Supt. E. F. Peck, recommending its use.

THE SENSIBLE AUTOMATIC PACKING CO., of Chicago, had for circulation an extremely pretty little circular, the cover of which was as novel as the inside reading was pithy and pertinent. This specialty is a flax packing, with a pure Para rubber core and a wax lubricant, "made upon honor."

THE MUNSON BELTING CO. were out in force, despite the distance from Chicago, being represented by Vice-President Groetzinger, Col. J.H. Shay, who was also accompanied by his brother, Mr. J. W. Shay, and the New York agent, Mr. Gabel. They did not leave without doing some excellent business.

THE WESTERN ELECTRIC CO., of Chicago and New York, were represented by Mr. Chas. A. Brown, who, from his active participation in the affairs of the Association, and his interest in electric lighting generally, finds that conventions are times of but scant leisure.

THE CENTRAL ELECTRIC CO. were ably and adequately represented by Mr. Geo. A. McKinlock, who has availed himself of his visit East to carry on one or two business negotiations of magnitude and importance.

J. J. RYAN & CO., brass founders and finishers, of Chicago, issued a neat type-written circular calling attention to the facilities of their brass foundry for electrical work. They have 32 furnaces, a smelting capacity of 10,000 lbs. of brass per day, room for 40 moulders, and floor space of 20,000 square feet.

THE PARKER-RUSSELL CO., of St. Louis, makers of carbons, were represented very successfully by Mr. D. R. Russell, who rarely, if ever, misses a Convention.

THE FORT WAYNE ELECTRIC CO. were represented by Messrs. Slattery, Morrison and Wilbur.

THE BRIDGEPORT BRASS CO. was represented by Mr. H. D. Stanley.

MR. C. O. BAKER, JR., represented the platinum interests in the Convention halls.

THE CHALMERS-SPENCE CO. distributed pamphlets in regard to the asbestos manufactures.

THE C. & C. MOTOR CO. were represented by Messrs. Lufkin & Hall. The paper by the former, printed in this issue, was one of the most interesting and valuable ever brought before the Association.

THE GREAT WESTERN ELECTRIC SUPPLY CO. was ably represented by Mr. Geo. Cutter himself, who found so many interested in the new enterprise he is pushing forward into leadership so magnificently that he got little time for social occupations and relaxations. It is whispered that Mr. Cutter found opportunity to perfect some of his arrangements for the extension of his company's business, and that he has already made his arrangements with the Union Electric Co., of Pittsburgh, as an Eastern branch.

HOLMES, BOOTH & HAYDENS put their best foot forward in Mr. Theo. Larbig, who has charge of their electrical sales.

MR. L. W. SERRELL, JR., was present, not only in his own behalf as engineer and expert, but to represent the Milliken pole, of which he has already sold several thousand in the new field of railway electrical work.

THE E. P. GLEASON MANUFACTURING CO., who make so large a line of electrical fixture specialties, glassware, etc., were represented by Mr. W. F. Cullen, who has been present at so many meetings.

MR. C. S. VAN NUIS, the builder of heavy current switches, was on the ground to explain the peculiar felicity of their name. The article in THE ELECTRICAL ENGINEER of August 20 served him as an excellent basis for a talk on the merits of the "Ajax."

THE AMERICAN ELECTRICAL WORKS sent Mr. P. C. Ackerman to represent them.

MR. C. R. VINCENT was present to answer for his firm and for the Ball engine.

THE FIELD ENGINEERING CO. were represented by Mr. C. J. Field, who had snatched a day or two from his pressing engagements elsewhere in Jersey to take a brief spell of leisure at the Cape.

THE EMPIRE CITY ELECTRIC CO. sent to the front their president, Gen. O. E. Madden, who, it is needless to say, was a leader in all the festivities as well as business proceedings of the occasion.

THE THOMPSON-HOUSTON CO., while it was strangely and sadly without representatives from its Eastern end of the line, owing to the terrific rush of business, found a good spokesman in Mr. H. H. Small, from Chicago, and Mr. W. F. Davidson, from Michigan.

MR. A. F. MOORE was on hand to represent his well-known wires. He has just brought out a most admirable and complete catalogue of his manufactures.

H. A. CLEVERLY, of the Cleverly Electrical Works, found no difficulty in coming on from Philadelphia, and talking motors and kindred topics.

THE FOREST CITY ELECTRIC WORKS were represented by Mr. W. B. Cleveland, of switch and cut-out fame. Mr. Cleveland had a new lamp hanger to bring to notice.

THE BRUSH ELECTRIC CO. sent Mr. C. C. Curtis, of Cleveland, as their representative.

CLOWER & HARRIS were represented by Mr. D. M. Clower, a good type from Dallas, Tex., of the spirit that animates the New South.

THE SHULTZ BELTING CO. were represented by Mr. A. B. Laurence, who showed a full line of the Shultz belting and pulley covering specialties.

THE EDDY ELECTRIC MOTOR CO. were represented by Messrs. Baird, Newton and McIntire.

THE METROPOLITAN RUBBER CO. were represented by Mr. C. A. Place, president, and Mr. Geo. H. Meeker, showing their cheap hard rubber tube for insulating purposes. The company also make rubber gloves for linemen.

THE ILLINOIS ELECTRIC MATERIAL CO., of Chicago, who handle the Bishop wires and cables and other specialties, and are making a fine record as a new concern, were well represented by their energetic young president, Mr. H. S. Winston, who was unfortunately called away suddenly, to close up a large business deal.

LITTLE, MCDONALD & CO., the electrical engineers and supply agents of Buffalo, were represented by Mr. W. H. McDonald.

THE WM. POWELL CO., of Cincinnati, O.—Mr. James Powell, who represented this company at Cape May, showed a fine line of samples of lubricating devices for all purposes. Among these was the Powell patent improved signal oiler. In this device the flow of oil can be instantly stopped or started without changing the feed, as the operation of the signal lever is independent of the feed regulator. The filling hole on the top cap is covered by the Powell patent snap lever, which can be readily moved either side to expose the hole. Their triple and double dynamo sight feed oil cups embody the same principles and are admirably constructed.

FINANCIAL MARKET.

QUOTATIONS ON ELECTRICAL STOCKS.

Mr. F. Z. Maguire, Electrical Securities, of 18 Wall street, this city, reports the following quotations of August 23 from New York, Boston and Washington :—

ANNUAL CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS.

THE Saturday following the Summer Convention of the National Electric Light Association has for some years past been a "red letter" day with members of the national fraternity from all parts of the country. On that day the American Electrical Works, of Providence, have been accustomed to give their Annual Clambake, and all who can possibly attend have been wont to hie to the Vue de l'Eau Club, and bury the hatchet of business competition and join with Messrs. Phillips and Sawyer in having a royal good time. Last Saturday was no exception to the rule, and about 160 gentlemen enjoyed the hospitality of Mr. Phillips and talked over old times while they "wrestled" with the festive and succulent clam. A large number went down from New York on the Providence boat on Friday night, and quite a large contingent traveled over from Boston on the nine o'clock train. All joined forces on the eleven o'clock boat from Providence to the Vue de l'Eau Club, where the usual lunch and bowl of Phillips' punch was awaiting them. Tall white hats and silk hats received the usual careful attention, and the more inexperienced of the guests were warned at the outset by someone pointing out the tattered remains of Mr. Fred. Gilbert's hat of past years, which was still decorating the top of a sixty-foot telegraph pole, where it had been set with all honors by some daring and agile member.

The New York and Boston members soon engaged in a friendly game of baseball, in which Boston came out with flying colors, having defeated New York by 28 to 23, with 7 home runs. The weather, though a little unpropitious in the morning, brightened up wonderfully, and everyone had a good time. The usual foot-ball was there, which got in some excellent work on the hats and heads of the unsuspecting. Opportunities were also afforded for testing one's expertness with the rifle, or his strength with the sledge-hammer, or even one's lung capacity, by blowing into a recording machine. At 3 o'clock the dinner commenced, after a speech of welcome from Mr. Geo. S. Bowen, father of the National Electric Light Association, and as an interesting memento of the occasion, coupled with a desire, doubtless, on the part of Messrs. Phillips & Sawyer, to make Rome howl (speaking classically), every one was provided with the latest musical novelty unearthed by Stanley from the darkest and most uncivilized part of the dark Continent, appropriately termed a "Squawkophone." These instruments bear a strong resemblance to what in happy childhood's day we termed a "devil's fiddle;" anyhow, they did undoubtedly make that kind of noise. Valuable instructions, together with a complete history of the wonderful discovery of this instrument of torture in the backwoods of Africa (please do not confound these with the suburbs of Providence), were enclosed in each squawkophone. The menu, as usual, was excellent. After dinner Mr. O. E. Madden officiated as "toast master," and introduced the various speakers, who all spoke briefly and to the point. The toasts and speakers were as follows:

1. Eugene F. Phillips, President Americen Electrical Works; our host and everybody's friend. E. F. PHILLIPS.
2. The Rhode Island Clam, the juiciest of the juicy; evidently of ancient origin, being represented in the Vulgate by the sixteenth letter of the alphabet. J. M. ADDEMAN.
3. The Telegraph; the first practical application of electricity by a modest old timer. SUEL SMITH.
4. The Telephone; speechless, yet master of all languages; there is no discount on this or on the rates; will be responded to by one who got in early. H. L. STORKE.
5. Electric Light and Power; safe, reliable, economical and adapted to all uses except electrocution. MARSDEN J. PERRY.
6. The Electrical Press; to our faults a little blind; to our virtues ever kind. T. C. MARTIN.

Other gentlemen were also called upon.

Three cheers and a tiger were then given for Mr. Phillips, and the twelfth clam bake, of 1890 was at an end, most of the gentlemen returning by the 5:40 boat to Providence, where they separated for their various destinations.

THE GREAT WESTERN ELECTRIC SUPPLY CO.

The Great Western Electric Supply Co. have got in a large invoice of telegraph apparatus and their "learners' outfits" are already being rapidly disposed of. They have several other large lots on the way and expect to control a good part of the Western business in telegraph apparatus. They are also selling large quantities of the Samsom batteries, which have heretofore been better known in the East than in the West. Their catalogue is expected out this week. That so young a firm should put out a complete and well-rounded catalogue in so short a time is a practicable impossibility, hence the firm, with their keen foresight of the requisites and possibilities of a full-fledged price list, have called this forerunner its "sketch-catalogue." Still our readers will not find much of the sketchy about what it offers, as all the standard supplies and specialties mentioned in it have been carefully worked out.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

JAMES H. MASON'S PRIMARY BATTERIES.

It is not alone in this country but abroad that Mr. Mason's primary batteries have won their way to favor and popularity. He is now enlarging his factory to double its size, at 118 and 120 Park avenue, Brooklyn, in order to meet the demand, and has lately been running night and day. Among his recent orders are one from Jamaica, West Indies, and another from Bengal, East Indies.

WESTERN TRADE NOTES.

THE ELECTRIC MERCHANDISE COMPANY, 11 East Adams street, Chicago, have been appointed agents for the Calorific Ventilating Heater Company, of Mansfield, O., manufacturers of Calorific Ventilating Heaters for street cars. This method of heating, and at the same time ventilating, street cars has met with great success, and has been largely adopted by street railway men all over the country. Mr. Mason, the general manager of the company, reports business as rushing and orders coming in all the time. They devote their undivided attention exclusively to the manufacture and sale of electric street railway supplies and specialties for all systems, and the advent of a concern handling these lines of goods alone has received the hearty commendation and patronage of the various electric street railway companies.

"WHITE CORE."—The well-known Bishop gutta percha white core wire is being used by the United States Electric Lighting Company in wiring the building of the Domestic Sewing Machine Company on Wabash avenue and Jackson street. The Illinois Electric Material Company are the general Western agents for these wires and cables.

NEW ENGLAND TRADE NOTES.

THE NEW ENGLAND WIRING AND CONSTRUCTION CO. have received the contract to wire the Master Builders' Association building on Devonshire street, Boston, for about 600 lights. Interior conduit will be used.

THE ELECTRIC GAS LIGHTING CO. have in their store ready for shipment to a hotel in Concord, N. H., a very handsome Tirrell drop annunciator, 3 ft. 6 in. wide by 4 ft. 6 in. high, made of quartered oak, and finished in their best style. The annunciator will accomodate from 125 to 150 rooms, and reflects credit on the builders.

THE STANDARD ELECTRIC CO., OF VERMONT, have recently made the following sales of electric light apparatus: The National Needle Company, Springfield, Mass., 300 light plant; Ashley & Bayley, Patterson, N. J., 500 light plant; The Cordis Mills, Milbury, Mass., 300 light plant; and the Republican Press Association, Concord, N. H., 300 light plant. The Standard Company are gradually making a reputation for their dynamos as a reliable and slow speed machine of minimum weight.

THE WAINWRIGHT MANUFACTURING CO., OF MASSACHUSETTS, have sold a 700 horse power heater to the New Bedford Gas Light Company, New Bedford, Mass.; a 300 horse power heater to the Clinton Electric Light Company; a 75 horse power heater to the Westinghouse Electric Light Company at Ogden, O.; and an 80 and a 30 horse power heater to the Ball Engine Company, of New York.

THE RICE AUTOMATIC COMPOUND ENGINE.

WE illustrate herewith two of the newest types of tandem compound engines, built by the John T. Noye Manufacturing Company, Buffalo, N. Y., under the patents of Mr. F. B. Rice, the well-known engineer. Fig. 1 represents an engine for duties up to 100-horse power, and Fig. 2 a larger one, designed for heavy loads. In the former the frame is of the same form as that used for the standard simple Rice engines, and can be made self-contained or with outside bearing, to suit special local requirements. The governor is inside the crank disc, and operates automatically the high and the low pressure valve. Either of these valves can be set independently of the other, while the engine is in motion, and both are balanced for all pressure higher than the exhaust.

It has been demonstrated that, with a full head of steam on, both valves can be moved by the pressure of two fingers on the valve stem. The valves take steam from the inside, so that, if it is desired to ascertain whether they are tight, they can be operated with the chest-cover off. The patented pressure plate, of Mr. Rice's design, forms a valve for the escape of water and for relieving over-pressure in the cylinders. The lubrication has been made as nearly perfect as possible; every oil-cup is stationary, and provided with sight feed and adjustable cut-off.

The compactness, smooth running, and high economy of this engine have strongly commended it to electric light companies,

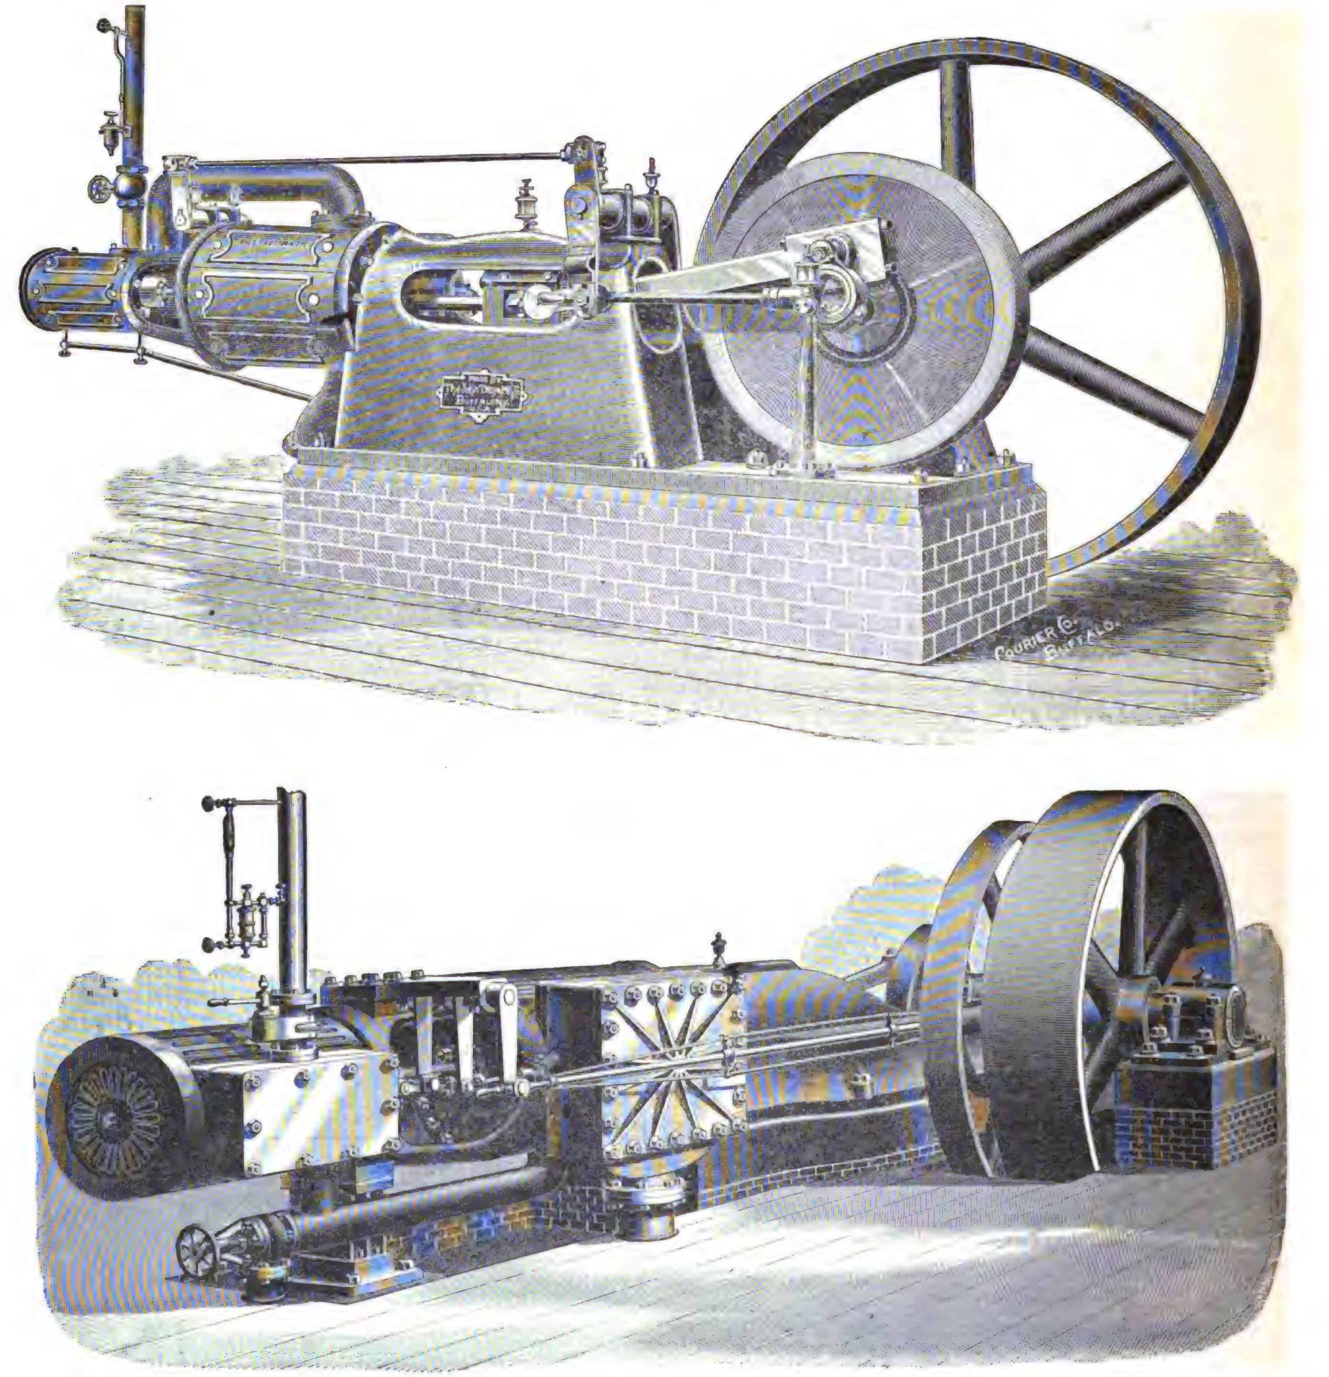
among whom it is already in extensive use. For mills and factories it has also proved to be highly desirable.

The heavy-duty Rice engine, represented in Fig. 2, as seen from the rear, shows clearly the valve motion and the governor, as well as the cylinders and frame.

The reader will note the low and unusually heavy frame, which is about twenty-five per cent. heavier than that of the standard engine. The increase in mass, however, has not been allowed to detract from the looks of the engine, but is distributed with such nice judgment so as to give it an appearance of graceful solidity to please the eye.

With two exceptions, frame and governor, this heavy-duty Rice engine is practically identical in construction with the standard tandem compound engine described above. The crank disc being too small for the governing mechanism required on so large an engine, it has been found best to place the governor in the fly-wheel, or, in some cases, in a wheel of its own. The valve is then driven from a separate eccentric on the shaft; both valves being driven automatically by the governor. The valve itself is of the well-known gridiron pattern, with four ports, and is so nicely balanced that it can easily be operated by hand, even when under full steam pressure.

The main bearing is provided with quarter boxes, in order that the wear may be taken up in any or all directions. These boxes are lined with genuine Babbitt metal, and then bored out to a perfect fit. The connecting-rod is of forged steel, with a loop to contain the brasses for the crank-pin. This construction is more costly than that in the standard engine, but is warranted by the additional safety and strength which it gives. The crosshead has a suitable take up for wear, and is so arranged that it cannot be tightened to the point of cutting. Engineers will particularly appreciate the fact that in this engine the low-pressure piston head can be removed without disconnecting the high-pressure, and of the arrangement by which steam may be used in either cylinder without employing the other. Thus, if the water supply becomes scant, making the condenser unavailable, the high-pressure cylinder may be used alone, giving three-fourths of the engine's full capacity.



FIGS. 1 AND 2.—THE RICE AUTOMATIC COMPOUND ENGINES.

Great weight and solidity, few and simple parts, high fuel economy, adaptability for long runs, large wearing surfaces, smallest safe clearance, and a regulation so sensitive as to keep at less than one per cent. the variation from full load to no load, are among the points which contribute to the success of this new type of engine.

EDITORIAL ANNOUNCEMENTS

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. X. NEW YORK, SEPTEMBER 3, 1890. No. 122

The laws of Nature are the thoughts of God.—Oersted.

ELECTRIC RAPID TRANSIT IN CITIES.

SOME very interesting information has just been issued by the Census Bureau, in a bulletin of which Prof. H. C. Adams is the author, giving statistics as to the rapid transit facilities in this country in cities of over 50,000 inhabitants. There are about fifty such cities. We append two tables containing the data :

Year.	Total mileage.	Increase. Miles.	Increase. Per ct.
1880	1,689.54		
1881	1,765.95	76.41	4.52
1882	1,875.10	109.15	6.18
1883	1,941.49	66.39	3.54
1884	2,051.84	90.35	4.65
1885	2,149.66	117.82	5.80
1886	2,289.91	140.25	6.52
1887	2,597.16	307.25	13.42
1888	2,854.94	257.78	9.93
1889	3,150.93	295.99	10.37
Total		1,461.39	86.50

The per cent. of total mileage of fifty-six principal cities operated by various kinds of motive power was :—

	Miles.	Per cent.
Animal power	2,351.10	74.62
Electricity	260.36	8.26
Cable	255.87	8.12
Steam (elevated roads)	61.79	1.96
Steam (surface roads)	221.81	7.04
Total	3,150.93	100.00

The length of line assigned to each of the five leading cities in 1889 was as follows :—Philadelphia, 283.47 miles ; Boston, 200.86 ; Chicago, 184.78 ; New York, 177.10 ; Brooklyn, 164.44. The number of miles assigned to each city is as follows :—New York, 368.62 ; Chicago, 365.50 ; Boston, 329.47 ; Brooklyn, 324.63 ; Philadelphia, 324.21.

The apparent preponderance of Brooklyn and Philadelphia is explained by the fact that in those cities the roads are often single track, going out on one street and returning by another. New York, for example, has 161 miles of double-track road and Philadelphia only 39.

But the main point of interest is the relation between electricity and the other motive powers. The figures above show that in 56 leading cities it is only 8.26 per cent. —a respectable figure, it is true, but still small. On the other hand, the figures for the whole country, as we had occasion to prove recently, are very different. They run thus:—

Miles of horse railway,	5,902½
" " electric "	1,753
" " dummy "	556
Cable,	441
Total mileage,	8,652½
Number of electric roads,	264
" " cable "	44

Here, it is seen, electricity is more than 25 per cent. already of the total mileage. It is also more than 25 per cent. of the total number of roads, there being nearly 1,000 in all, but only 807 in independent operation.

The question arises : How shall the proportion of electrical operation in the cities be brought up to that of the country as a whole? Will it be by means of the overhead system? We doubt very much if it will be through the latter agency. In some cities, such as Boston and Minneapolis, the prejudice has been overcome, but elsewhere it is still as invincible as ever. This leaves the field to the storage battery, unless an elevated track be erected ; or unless a good conduit system is forthcoming. But where shall we find a good conduit system to-day ?

NEW WORK IN THERMO-ELECTRICITY.

THOSE who study the signs of the times cannot fail to be impressed with the efforts which are now being put forth in many directions to bring within the range of commercial practicability the thermopile. Though known for more than half a century, this form of electric generator has not yet emerged from the laboratory of the experimenter, except in its application to a few special forms of work where its great convenience has put it before the voltaic cell, as a working apparatus. The acknowledged low efficiency of the thermopile must, no doubt, be looked to as the cause of the backward state in which it has up to recent times been allowed to remain ; but the energy with which the problem is now being attacked leads us to believe that the near future may place this form of electric generator in a position of considerable importance. The direction in which a number of inventors are working at the present hour is pointed out in an article appearing on another page, from which it will be evident that the combination of a few dozen elements heretofore employed is giving place to a series embodying thousands of elements and heated by furnaces of large dimensions. The special methods adopted are also worthy of notice. Thus, Mr. Edison seeks to obtain an increased effect by constantly renewing the surface of contact of the two elements, by transferring the heated portion of one element to a relatively cooler point. This he accomplishes by employing as one of the elements a revolving disc. Mr. Cox, on the

other hand, has introduced a novel principle of construction, effecting what he terms a fall in thermic potential.

The extent to which these and similar modifications improve the working capacity of the thermopile remains to be determined, but enough has been said to show that the interest in this old method of generating electricity has been remarkably renewed. Whether or not, the thermopile in its modifications will realize the expectations of those who look to the universal generation of current direct from coal, we will not undertake to say, but the subject is certainly of sufficient interest to warrant the most attentive study and most exhaustive experiment. The steam engine and the dynamo are a combination which it may take a long time to supersede but the victory of the dynamo over the voltaic battery was not accomplished in a day nor without the expenditure of many weary years of toil and thought and outlay.

FAN MOTORS FOR WINTER SERVICE.

As far as our observation goes, the tendency is pretty general among central station managers to regard the electric fan business as one that belongs peculiarly to the summer time and is killed off by the first frost. Such an idea seems to us to be without foundation. We believe that there is work, and plenty of it, for fan motors the year around. In fact, they who have enjoyed their cooling breezes during the dogdays are not likely to be ungrateful or of short memory when the wearisome months of stuffy heat and slow suffocation come again. If you make mankind happy now, said Sydney Smith, you make them happy twenty years hence by the recollection of it; but it is natural and human not to dwell simply in recollections, but to enjoy, if possible, a renewal of pleasurable sensations. Our many central station readers will confer new benefits on the public by pushing the fan motor industry as well during January as in July; and they can render many a meeting hall, ball room, school room or office fitter for occupancy and use. We do not see why the little motors could not also be attached to ozone generators and thus not only agitate the air but freshen and purify it directly.

A NEW CONSTRUCTION IN ELECTRIC GENERATORS.

While the number of methods of generating an electric current actually employed in practice is very limited, the number of possible ones is quite large. A most interesting addition to the latter is that which we describe in another column, and is due to Mr. Edison. He has taken up for investigation the irresistible force exerted by the expansion of bodies due to heating. As in his thermo-magnetic generator, Mr. Edison employs nickel as the metal subjected to the heat, on account of its non-corroding properties. While this is undoubtedly a most ingenious combination, it is hardly likely that the new generator will become commercially practicable. The effect obtainable by the rupture of the magnetic circuit to the extent described must obviously be of comparatively small amount, and to this must be added the fact that the rate at which the makes and breaks can be obtained is limited by the rate at which the expanding metal can be heated and cooled so as to give the desired expansion. Nevertheless, the method pointed out will prove of interest as showing another of the many ways in which heat can be applied to the generation of current.

Earth Polarization by Electric Railways.

The further investigations of Mr. Cuttriss into the nature of the disturbance which has affected the Commercial cable running parallel with the Coney Island Electric Railway has disclosed an interesting fact, demonstrating the action of the current on the earth in the vicinity of the rails. It is natural to expect that, with a ground return, the earth would be polarized, and under favorable conditions gas would be generated by electrolytic action, and would by preference be spread out over a large area of ground. As Mr. Cuttriss' experiments prove, the increase of the potential between New York and Coney Island, due to these independent and variable currents set up between the rails and the sheathing of the conductor, is sufficient to explain the phenomena observed. According to Mr. Cuttriss, therefore, we have here to deal with earth current phenomena rather than with direct dynamic induction, and hence the means to be adopted to avoid the disturbance at once assume a more troublesome aspect. As pointed out, relief might be obtained by a return cable identical in every respect with the main cable, a condition which, of course, is exceedingly difficult to fulfill.

A Novel Telephonic Reaction.

We have recently had our attention called to an interesting phenomenon in connection with the telephone, which might be looked upon with suspicion by the uninitiated. While Messrs. Hibbard and Pickernell were conversing recently over one of the lines of the Long Distance Telephone Co., the former, in order to shut out some conversation, placed the receiver with the diaphragm end over the mouth-piece of the long distance transmitter. The receivers at both ends at once began to give out a musical sound, which continued until the receiver was withdrawn from the mouthpiece of the transmitter. Investigation proved that the effect was due to an action quite similar to that employed in the well-known buzzer or vibrating bell. An original impulse imparted to the transmitter is conveyed electrically through the primary and secondary circuits to the receiver, which in turn throws it back upon the transmitter through the intervening air, thus constituting a complete electric and acoustic cycle. This battledore and shuttlecock action between receiver and transmitter is continuous as long as the receiver is held against the transmitter, and gives rise to a musical note of high pitch and great uniformity. Of course it requires a powerful transmitter to produce the phenomenon, the ordinary Blake instrument being incapable of demonstrating it. The effect produced is decidedly novel and the experiment is well worthy of repetition.

Arc Light Carbon Manufacture.

The news from Cleveland published in our columns this week, as to a consolidation of arc light carbon industries there, is interesting. It will be noted that the plan proposed will, according to these reports, place a large proportion of the carbon factories under one management. Efforts to do this have been made before, of one kind and another, but this is the first to look like definite success.

POLARIZATION OF THE EARTH BY HEAVY CURRENTS.

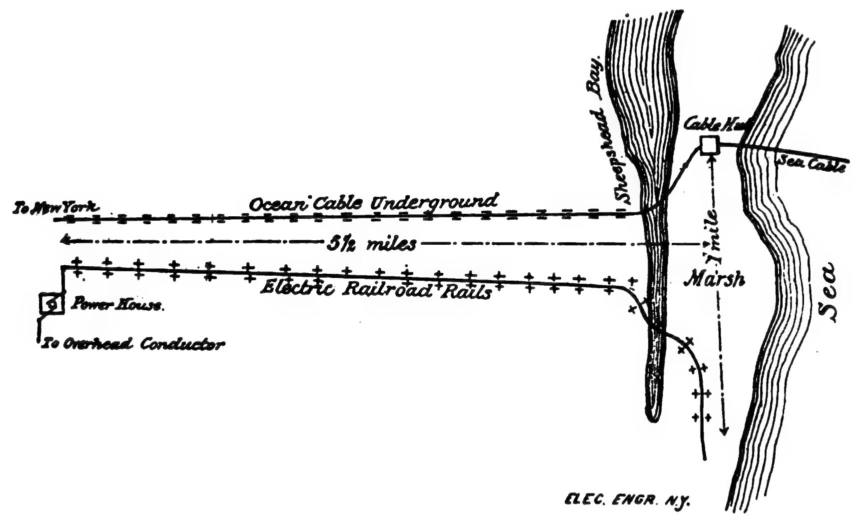
BY CHARLES CUTTRISS.

WHILE investigating further the causes of the disturbances experienced when testing the Commercial Cable Co.'s cable which lands at Coney Island, an account of which will be found in the THE ELECTRICAL ENGINEER of Aug. 6, certain phenomena have been noticed which may be interesting as showing the effect of heavy currents in polarizing the ground when it is used as a return circuit for an electric road, and also the great distance at which such effects are felt.

On Sunday, Aug. 17, an attempt was made from my office in the Drexel building, New York, to take the usual weekly test of the condition of the cable, but without success, as, owing to the violent and erratic movements of the mirror, it was impossible to get a reliable reading. It was then determined to measure, if possible, the differences of potential that caused such disturbances. In order to make the method of procedure clear, it will be well to state that the underground circuits of the company extend from Wall street in a northerly direction to the Bronx river, a distance of about 12 miles and in a southerly direction to Coney Island, also about 12 miles. As there is nothing to my knowlege in the vicinity of the Bronx river terminus to cause any electrical disturbance of the earth's potential, the grounding at that station and at Coney Island of one of their wires gives a very ready way of detecting in New York any variations of potential that may take place at either end.

The first series of experiments were made between the hours of 10:45 a. m., and noon of August 17, and showed that between Bronx river and New York there was a fairly steady difference of potential of from .8 to 1 volt; but between New York and Coney Island there was a difference of potential varying rapidly from .1 to 3.5 volts, the extreme fluctuations often occurring in 4 or 5 seconds. The potential difference between Bronx river and Coney Island was about the same as between New York and Coney Island, or perhaps a trifle higher, and also very unsteady.

It was useless to do anything more until the electric road closed down, so the experiments were abandoned till midnight. At 12:25 a. m. I found a very heavy current between Coney Island and New York, but could not detect the running of any cars. Measurements now showed a positive difference of potential of 4.5 volts; this remained fairly steady till about 1 a. m., when the potential commenced to fall slowly and steadily. At 1:15 a. m. the galvanometer denoted an equal potential at both ends of the line, but the movement of the mirror still continued, slowly crossing the zero and indicating an opposite, or negative, potential wave, which by 1:25 a. m. had reached 3.5 volts negative. It then began to drop, reaching zero at 1:40 a. m., and continued on until it showed a positive difference of .8 volt, where it remained steady, showing that the earth at Coney Island had become normal, as the difference of .8 volt corresponded with the reading between New York and Bronx river. I might state that the New York ground potential was checked off by the Bronx river circuit every five minutes in order to make sure that the variations were not due to local causes.



EARTH POLARIZATION DUE TO ELECTRIC RAILWAYS.

From the results obtained in the above experiments it is quite evident that there is an actual polarization of the ground for an unknown distance from the rails of the electric road. The accompanying diagram will make clear the relative positions of the electric road and the ocean cable. The first long, positive (+) current, I think, must be caused by a direct flow of current from the rails through the sea and across the marsh and Sheepshead Bay to the sheathing of the cable; consequently when the current is cut off from the rails this direct current gradually drops, and as the current due to the polarization asserts itself, for an instant the ground at the point of connection between the conductor and sheathing becomes neutral from the action of equal and opposite forces. But, as the negative current from the ground surrounding the cable discharges along the sheathing, that being the path of least resistance, it produces a negative potential at the end of the conduc-

tor, which rises to a maximum in a few minutes and then gradually dies away as the condition of the ground becomes normal. If the normal condition of the ground can thus be raised 4.3 volts by a disturbing force at a distance of ½ mile, the close proximity of these two systems would certainly render the practical working of the weaker one—the cable—almost an impossibility, even if, as suggested by Mr. T. D. Lockwood, a duplicate cable were to be laid, as it is mechanically impracticable to construct two cables in which the dielectric resistance, copper resistance, and capacity shall be identical. Consequently, a variation in either of these respects must make itself manifest when the cores are subjected for a considerable distance to violent and rapid electrical strains.

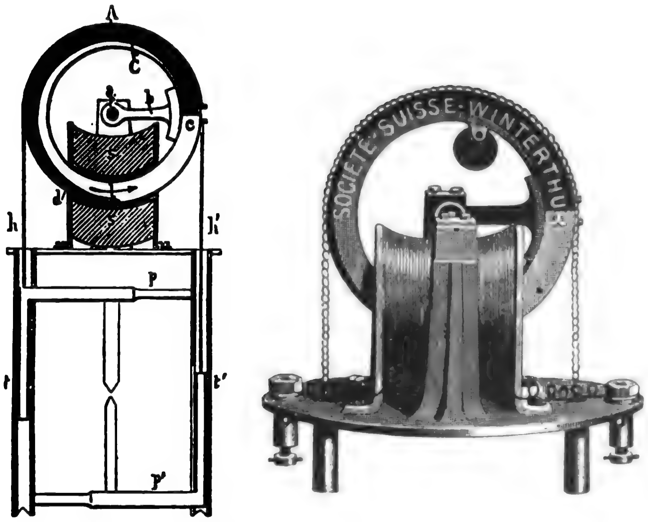
The great difference in this problem over that of equalizing telephone or telegraph circuits rests in the extreme delicacy of the receiving apparatus, and the enormous electro-static capacity of long lengths of submarine cable.

THE ZWEIFEL ARC LAMP.[1]

DURING late years such a variety of arc lamps have been described that it is very difficult to find any novelty in the designs that still rise to the surface every day.

Among the different apparatus exhibited last year in the Machinery Hall, at the Exhibition, a lamp was noticed, not lacking in originality, and which is certainly one of the most simple regulators yet devised.

A ring composed either of iron or copper, moving inside of a solenoid, and actuating the two carbon holders by means of two small chains, suffice to produce a shapely arc and to regulate its operation. The illustration, Fig. 1, shows



FIGS. 1 AND 2.—THE ZWEIFEL ARC LAMP.

the mechanism of the lamp diagrammatically, and Figs. 2 and 3 the working parts and lamp complete in perspective. The ring A consists essentially of one part of iron, cross hatched in Fig. 1, whose section increases from *d* to *e* and which is supported by an arm *b*; the iron portion is completed by the part *c c* of brass, in such a manner that the grouping of the iron, brass, and the arm *b* results in a perfect equilibrium about the axis *a*. To the ring are attached the ends of two small chains *h h'*, on which the carbon holders *p p'* are hung and which are guided within the tubes *t* and *t'*.

The lower carbon holder *p'* is heavier than the upper one *p*, and, therefore, tends to draw apart the holders and to draw the ring to one extremity of its arc of revolution, in which position it is shown.

When the solenoid *s* is traversed by an electric current its tendency is, on the contrary, through the current action upon the iron portion of the ring, to move in the direction of the arrow *l* and to bring together the two carbon holders. The solenoid is wound with fine wire and is placed in shunt to the two carbon holders. It consequently controls the difference of potential between the two carbons, or, in other words, the distance between them. It is important that this distance be maintained to obtain a regular light whose intensity may be adjusted at will by means of a suitable rheostat.

The operation of the lamp will now be readily understood. When no current traverses the lamp the unbalanced weight of the lower carbon holder *p'*, acting upon the little chain *h'*, causes the ring to turn from left to right

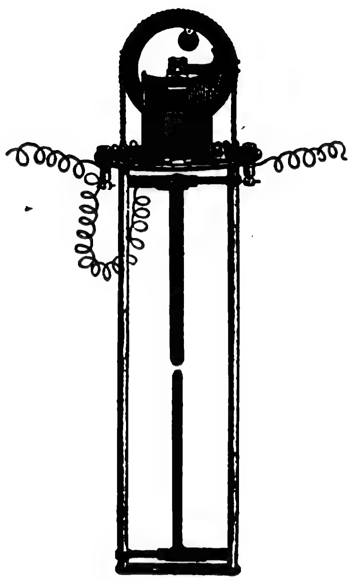


FIG. 3.—THE ZWEIFEL ARC LAMP.

with the result of putting it in the extreme position in which it is shown, and consequently drawing apart the carbons; but if the lamp is connected with a source of electricity the current will have no path across the carbons, but through the bobbin of the solenoid, which will act energetically upon the iron part of the ring, and moves it from right to left. The upper carbon then decends and the lower rises, until the two meet, when the whole current passes through them; the bobbin receiving no current, will have no influence upon the armature, and the overweight of *p'*, acting upon the ring in an opposite direction, the carbons separate and the arc forms.

As the arc lengthens, the current encounters more resistance across the carbons and a portion of it will again pass through the solenoid, which becomes more powerful as the arc lengthens.

THE ROVELLO ELECTROLYTIC PROCESS FOR EXTRACTING COPPER.[1]

THE cupriferous water obtained in the process of roasting copper pyrites in the manufacture of sulphuric acid is usually treated with iron filings, which precipitate the copper in the condition of an impure mass containing about 75 per cent. of copper, which it is necessary afterwards to compress, dry, melt, and refine. The object of M. Rovello's process is to electrolyze this cupriferous water in such a manner as to precipitate the copper in such a form as to render it immediately useful. His apparatus consists essentially of a large Daniell battery, the electro-negative elements of which are of sheet or cast-iron, instead of zinc, and are separated from the copper plates by porous partitions. The electromotive force of an element of this kind (iron-copper) being about .6 volt, a current of 200 amperes should be obtained with a battery of an internal

1. *L'Electricien.*

1. *La Lumière Electrique.*

resistance of .003 ohm, capable of precipitating (at the rate of 1.19 grammes per ampere hour) 6 kilogrammes (13 lbs.) of copper per hour. In order to lower the internal resistance to .003 ohm, it is necessary to use electrodes with large surfaces and diaphragms of very low specific resistance. The electrolytic batteries are built up of a series of wooden frames separating the cathodes from the anodes by membranes of parchment. The anodes and cathodes are respectively fastened together by bars of copper. The frames and parchments are pierced by four holes, in which are inserted four tubes. Two of these tubes communicate with the even elements and a funnel, and the other two with the odd elements and a second funnel. The cupriferous liquid is poured in in a narrow stream and passes through into the cathode compartments, and the solution of sulphate of iron is poured into the anode compartments. These liquids escape separately by the overflow pipes. The weakened solution of sulphate of copper may afterwards be completely exhausted in a second apparatus. The operation is carried on without help from any source of electricity other than the baths themselves, which are short-circuited.

RECENT ADVANCES IN THERMO-ELECTRIC GENERATORS.

Since the discovery of the thermo-electric principle of current generation by Seebeck, many devices and arrangements of metallic couples have been conceived with the object of increasing the effect obtainable; and though thermo-electric batteries have come into practical use to a limited extent for special purposes, the efforts of inventors have rightly been stimulated to test the principle in the construction of apparatus designed to give currents appli-

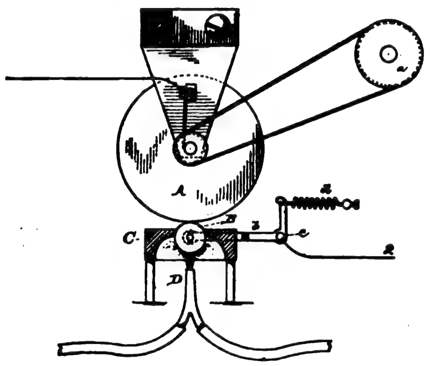

Fig. 1.—Edison's Thermo-Electric Generator.

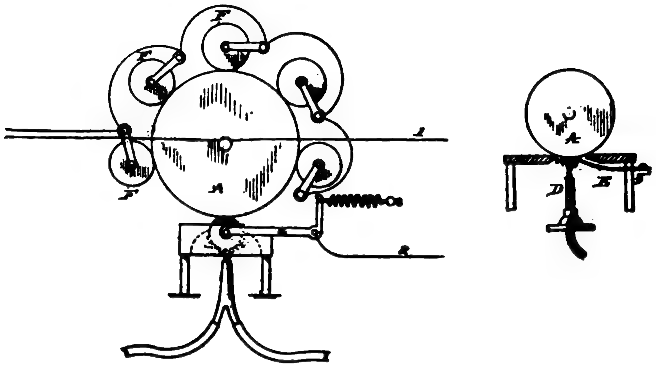
cable to a wider range of work such as electricity is applied to at the present day, and thus to realize to the full the dream of those who seek for the direct generation of electricity from coal.

In order to show the latest efforts in this direction, we desire to bring to the attention of our readers the work of a number of inventors, which embodies some new arrangements of an interesting character.

Among others, Mr. Edison has taken up the subject, and in seeking to increase the E. M. F., maintains the two thermo-electric metals at widely different temperatures at their points of contact. To do this, he rotates one or both of the metals so that they will have a traveling contact, one metal only being heated directly, and the other receiving heat by conduction at the point of contact. The moving of the cooler metal brings constantly new portions of the metal into contact with the heated metal, while other portions of the cooler metal are kept cool by the surrounding air, and thus a widely different temperature of the two metals is maintained, producing a more efficient couple.

This idea has been carried out in various ways by Mr. Edison, one of which is illustrated in the accompanying engraving, Fig. 1. Here A is a disc of iron which is kept in constant rotation. Bearing against one side of the disc A, is a smaller disc B, of copper. The latter is mounted upon an arm *b*, pivoted at the point *c*, and having attached to it a spring *d*, which acts to press the disc B constantly against the disc A. A shield C, of fire-brick, incloses the disc B, except on one side, where it projects through a slot in the shield to press against the disc A.

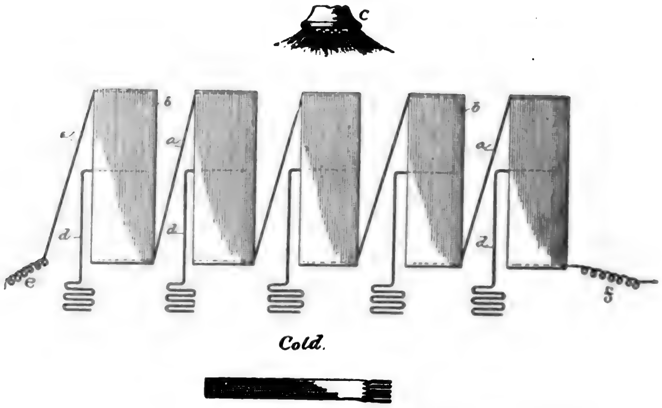
Heat is applied to the disc B within the shield. The lat-



Figs. 2 and 3.—Edison's Thermo-Electric Generator.

ter prevents the direct radiation of the heat from the burner to the disc A, so that the latter is heated only by conduction from the disc B. The disc A being rotated, its contact with B will be changed constantly to new points on the periphery of A, and hence the two metals will be maintained at widely different temperatures at their points of contact, the disc A being cooled by the surrounding air. Circuit-connections are maintained with the disc A by a spring bearing on its shaft, and with the disc B at the pivot of the arm *b*.

Instead of having the heated metal a rotating disc it may be a stationary plate E, as shown in Fig. 3. Again, one or more copper discs F, not directly heated, may bear upon the disc A, as shown in Fig. 2. These serve to assist the



Figs. 4 and 5.—The Cox Thermo-Electric Element.

cooling of the disc A, and produce an electromotive force which is much lower, of course, than that produced between the discs A and B; but it may be utilized through circuit-connections shown.

In seeking to increase the thermo-electric effect, Mr. Harry B. Cox, of New Haven, Conn., has struck out in another direction, and as a result of his experiments finds that the best results are obtained when the length of metal in circuit is as short as possible, and the fall in the "thermic potential" is as great as possible.

With these facts in view, Mr. Cox's object is to produce in a thermo-electric circuit as pronounced a fall in heat potential, and to produce as large a movement of heat within the circuit, as possible. This he accomplishes by the construction of his elements, one form of which is

shown in the accompanying engraving, Fig. 4. As will be seen, each thermo-couple consists of two elements *a*, *b*, composed of unlike metals joined together in the manner shown. The strips *a* extend from one end of one large element *b* to the opposite end of the next adjoining element, and heat is applied at *c*, to the junctions at corresponding ends of the elements. The opposite junctions are kept at as low a temperature as possible. A conducting or radiating strip *d*, of good conducting metal, is connected joined to the conducting or radiating strip *d*. The object of the strips *d* is to produce as great a fall in thermic potential between the junctions as possible.

It will be observed that the conductors or radiators, *d*, are connected between the junctions and extend out into the atmosphere. This prevents them from not only attaining the same temperature as the element, *b*, but in fact reduces the temperature of the element, and tends to very materially lower the temperature between the junctions, and thus produces the object sought for; that is, a pronounced fall in thermic potential.

In applying this form of thermo-element in practice Mr. Cox employs the arrangement illustrated in Fig. 6. The elements, it will be noted, are ranged in the form of a ring. A series of these rings is then piled one above the other and separated by insulating material. The interior surfaces are covered with fire-proof material, and the

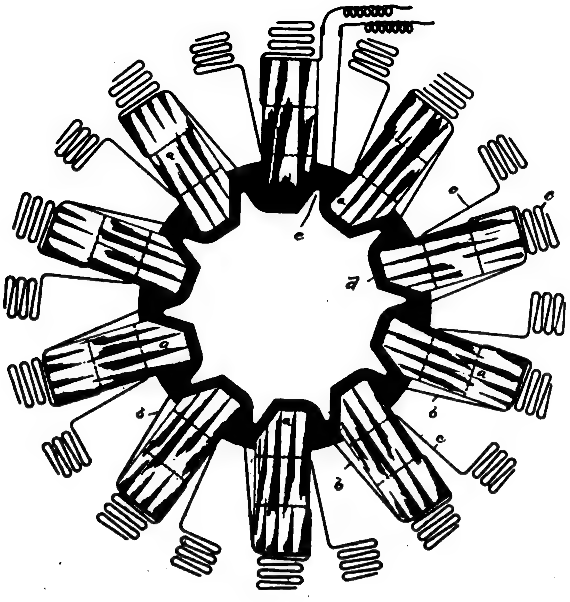


Fig. 6.

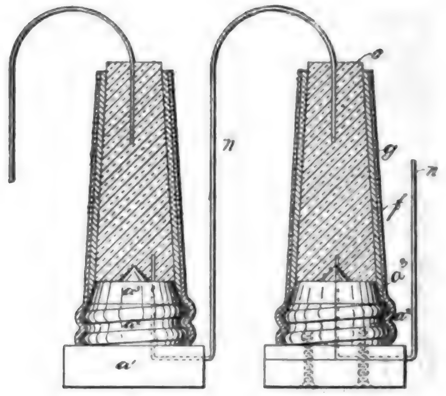

Fig. 8.

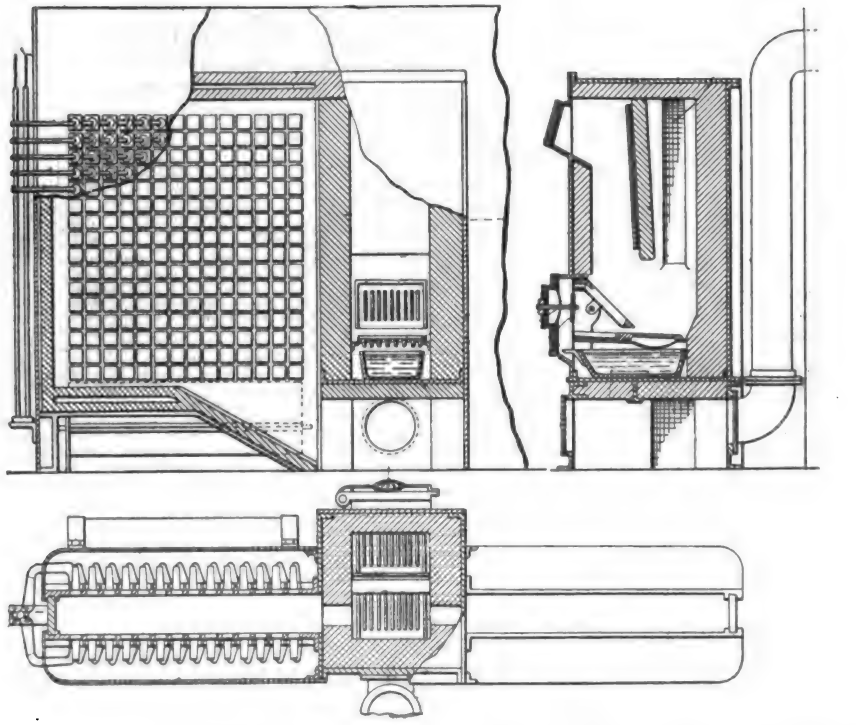

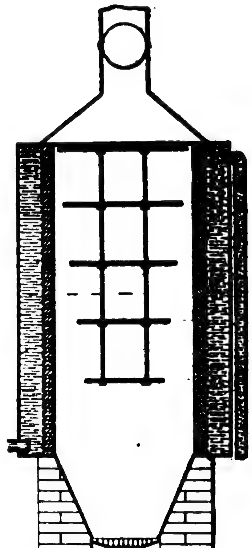

Fig. 7.

Figs. 6, 7, 8, 9, 10 and 11.—Recent Developments in Thermo-Electricity.

with and extends from the elements *b*, between the portions of the same exposed to heat and cold, toward the source of cold.

In connecting and constructing the parts the ends of the metal strips *a* and *d* are slit, as shown in Fig. 5, in such a manner that the metal composing the element *b* can be cast around and make a firm connection with it. The metal composing the element *b* is also cast around and thus whole constitutes a furnace arrangement such as shown in Fig. 7. In order to avoid unequal heating, a series of horizontal deflecting plates are placed on the interior of the furnace, so that the heated gases are evenly distributed to the exposed elements.

Finally, we would call the attention of our readers to a form of thermo-electric generator due to Mr. Hugo Mestern, in which the inventor has arranged his elements so

that one of the metals may be subjected with impunity to intense heat and still leave the other protected, though in close proximity to the former. The arrangement adopted is shown in the illustration, Fig. 8.

The negative electrode consists of a cast iron metal block composed of the square base a', with a screw-shaped part, a^2, above which is a circular end piece, a^3, terminating in a cone-point. In this metal block is placed the conducting-strip, *n*, which is cast in. A hollow asbestos covering sleeve, *f*, is cemented to the part, a^3, of each electrode, and the conical case, *g*, is screwed over a^2 and a^3. Through the screwing of the case the asbestos block has its lower end pressed firmly on the negative electrode, so that between the insulating-sleeve, *f*, and the parts a', a^2 and a^3 a complete junction is effected.

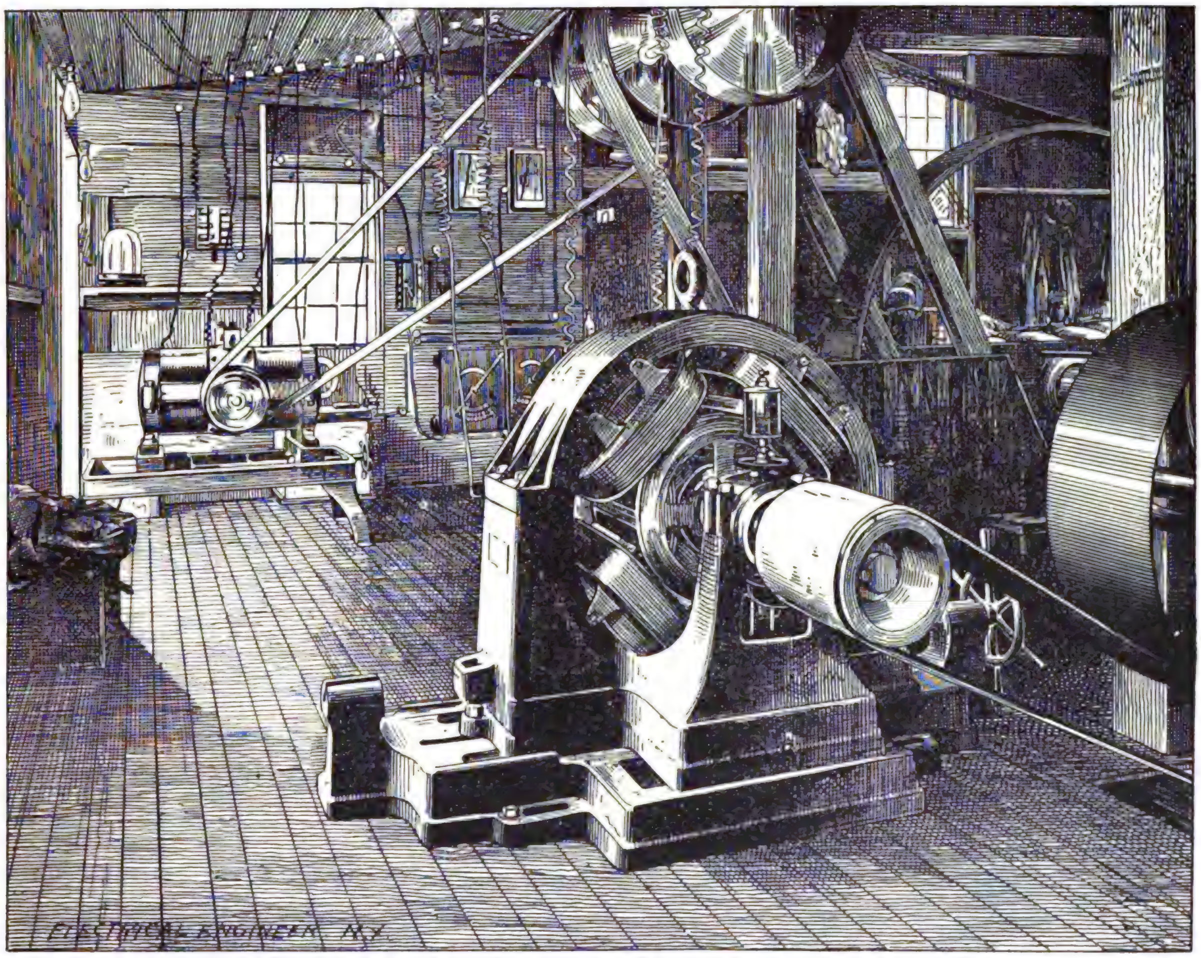
The conducting-strips, *n*, have their upper curved part terminating in the middle of the neighboring positive electrode. The fluid metal of the positive electrode, consisting of some easily-fusible metal, such as antimony, zinc, or an alloy, is then poured into the opening of the asbestos tube, *f*, and the row of elements is ready.

The elements constructed in the manner described are then arranged in a frame, two of which are placed in a furnace, the arrangement of which is shown in the engravings, Figs. 9, 10 and 11. The positive electrodes are kept as cool as possible, and for this purpose the battery is covered with a metal case, in which, through a regulator, cold air is admitted from the outside.

The construction of the elements has been so arranged that should the positive electrode, through the heating of the furnace-battery, be melted at its point of connection with the negative electrode, no escape of the melted metal or alloy can occur, owing to the construction of the asbestos sleeve and the protecting-mantle, so that any break down in the element is thus guarded against.

THE ELECTRIC GENERATING PLANT AT THE WILLOCK COAL MINE.

In our issue of August 20, we gave a detailed description of the underground electrical equipment installed at the First Pool Monongahela Coal Co.'s mines at Willock Station, Pa., by the Mill and Mine Electric Equipment Co., of Pittsburgh, Pa. This consisted of a number of the Hercules coal mining machines and a pump, driven by Tesla alternating motors built by the Westinghouse Company; and to complete the details we give in the accompanying engraving a view of the power installation. This consists of two 12 x 20 Carter engines and one 80 h. p. 3-wire alternating generator. As will be seen, the generator has four poles, and in order to obtain the quarter phase difference in the two branches of the 3-wire system, the armature is wound with two sets of four coils each which overlap each other. The field magnets are excited by a part of the armature current which is commutated, and the speed of the machine is such as to give 6,000 complete reversals per minute.



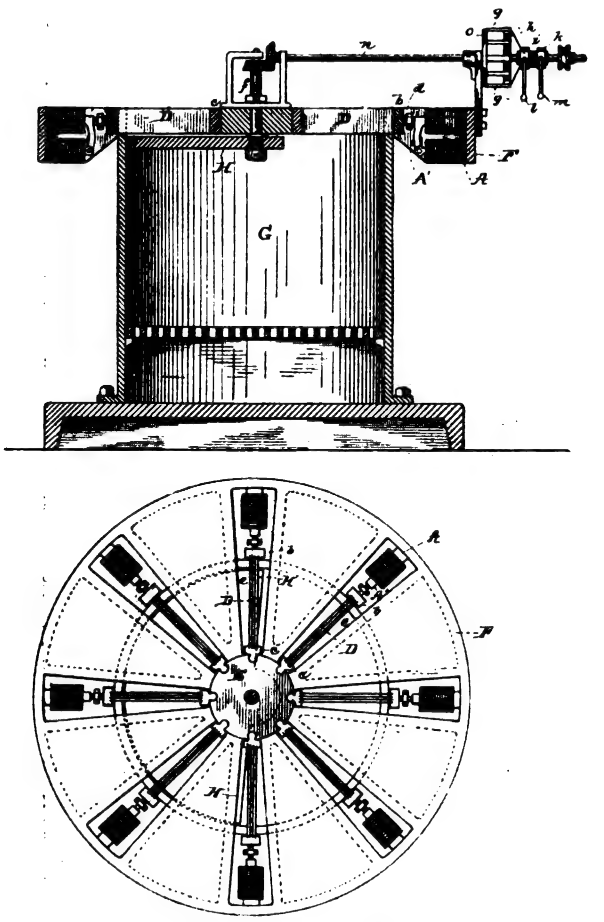
Electric Generating Plant at the Willock Coal Mine.

The Standard Electric Co., of Vermont, have received the contracts for a 300 light plant in the Sullaway Mills, Franklin Falls, N. H., and a 300 light plant for J. B. Van Sciver, Camden, N. J.

EDISON'S NOVEL ELECTRIC GENERATOR.

MANY attempts have been made heretofore to utilize in the operation of prime motors the expansion and contraction of solid matter; but the expansion and contraction between practicable limits is so small that no mechanical means has as yet been obtained which would utilize these small movements for practical purposes. The problem is to transform the exceedingly small movements, which can be obtained by the expansion and contraction of solid matter due to variations in temperature, into energy capable of practical use. Mr. Edison some time ago took up the study of this problem and has succeeded in designing an operative apparatus by applying the movements to the opening and closing of a magnetic circuit. The arrangement is based upon the well-known fact that the resistance of air to magnetic lines of force or stress is about twelve hundred times that of soft iron.

Now, if short stout magnets are divided into two parts, with their faces accurately ground to fit together like two



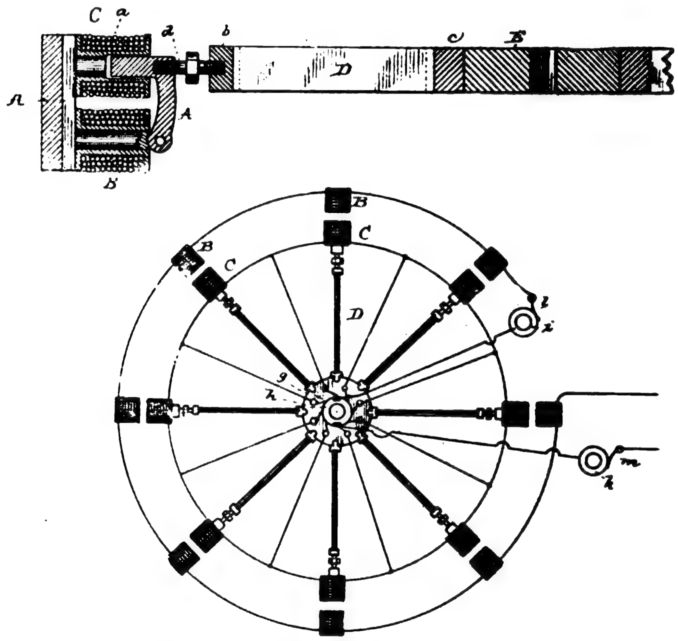
FIGS. 1 AND 2.—EDISON'S NEW ELECTRIC GENERATOR.

surface plates and are magnetized nearly to saturation, an enormous force is required to pull them apart and open the magnetic circuit; but if the faces are separated even to the slightest extent, say one two-hundredth part of an inch, the attraction is reduced enormously on account of the interposition in the magnetic circuit of a layer of air, whose specific resistance to magnetic stress is twelve hundred times greater than the iron. Mr. Edison has found that a large percentage of the force required to entirely open the magnetic circuit must be expended in producing this first slight separation of the surfaces, and hence the energy to be gained by a further separation of the surfaces is of much less importance.

If, now, the magnetic circuit be covered in part by wire through which a current is passed, it can be magnetized and, if it is also covered in part by other wire, particularly in the vicinity of the rupture of the circuit, induction waves will be produced in the latter coils when the magnetic circuit is opened or closed to the slight extent stated. This small movement being within the practical limits of the expansion and contraction of solid matter, Mr. Edison is thus enabled to obtain the full value of the almost irresistible force of expansion in solids for practical purposes.

The manner in which this has been carried out in practice is shown in the accompanying engravings, Figs. 1 and 2, which show the apparatus in section and in plan view, respectively. Fig. 3 shows one of the elements of the generator enlarged.

Each element of the generator is a magnetic circuit A, one portion A′ of which is pivoted upon the part A, the movements of the latter producing the opening and closing of the magnetic circuit at the point *a*, the surfaces being fitted accurately together. One side of the magnetic circuit is covered with energizing-coils B, while the other side, covering the point *a*, at which the magnetic circuit is opened and closed, is provided with the coils C in which current is induced. Thus it will be seen that the magnetic circuit is opened and closed directly within the coils C. The touching of the surfaces at *a* causes the lines of magnetic force to travel almost entirely through the iron forming the magnetic circuit, while the separation of these sur-



FIGS. 3 AND 4.—EDISON'S NEW ELECTRIC GENERATOR.

faces even to the slightest extent causes the lines of magnetic force to strike out through the surrounding coils C, and thus induce current in those coils. These lines of force are again withdrawn by the closing of the magnetic circuit, and thus a current of one direction is induced in the coils C when the magnetic circuit is opened, and a current of the other direction when the magnetic circuit is closed.

To move the pivoted part or keeper A′ of the magnetic circuit, there are attached to A′ a number of sheets D of nickel, which are secured to end pieces *b* *c*. Entering the end piece *b* and the keeper A′, and connecting them together, is a bolt *d*, by which the parts can be given the proper relative adjustment. The end piece *c* is set into the central hub E. A number of these elements are mounted in openings *e* in the top plate of the furnace, the top plate extending beyond the sides of the furnace, so as to keep the magnets away from the heat of the furnace and to permit them to be kept cool by the direct circulation of air around them.

The products of combustion from the furnace pass up through the openings in the nickel sheets D, and thus heat

them. When they are cold, or not subjected to the direct action of the heat, the magnetic circuits are opened, the sheets being maintained under stress by the magnetic attraction which tends to close the magnetic circuits.

A revolving shield, or director of the heat, H is mounted upon a shaft *f*, and carries the shield on its lower end within the furnace. This shield covers one-half of the openings *e* in the top plate, and, being revolved slowly, successively closes the openings on its advancing side and opens those on its retreating side. Thus one-half of the nickel sheets will be cooling while one-half will be heating, those that are cooling producing a current in one direction while those that are heating are producing a current in the other direction in the coils C.

For producing a continuous current, the coils, C, are connected together in a closed circuit, as shown in the diagram of the circuit connections, Fig. 4, while between the coils connections are made to commutator-springs, *g*, resting on a disc, *h*. This disc is of insulating material except at two opposite points in its periphery, where it is provided with plates of metal. These plates are connected with two rings, *i k*, upon which rest springs, *l m*. The springs, *g*, being stationary, and the disc, *h*, being rotated, the main circuit will be connected with the coils, C, through those springs, *g*, which rest upon the metal blocks in the disc, *h*, and thus the circuit-connections will be advanced with the movements of the shield, H, and a continuous current will be produced at the springs, *l m*. To take the commutator away from the influence of the heat, there is provided a horizontal shaft, *n*, which is connected by beveled gear with the vertical shaft, *f*, and has the same speed. A plate, *o*, carrying the stationary springs, *g*, is mounted upon the outer bearing of this shaft.

For energizing the coils, B, a separate source of energy may be used, or the coils may be supplied directly from the apparatus itself, as shown in Fig. 4, a galvanic battery being used to energize the coils in starting and being afterward removed from the circuit when the machine is started. It is evident that permanent magnets may be used in place of the electro-magnets, and that many forms of the expansible body can be utilized, but Mr. Edison prefers a divided body or one having thin walls, so that it can be quickly heated and cooled.

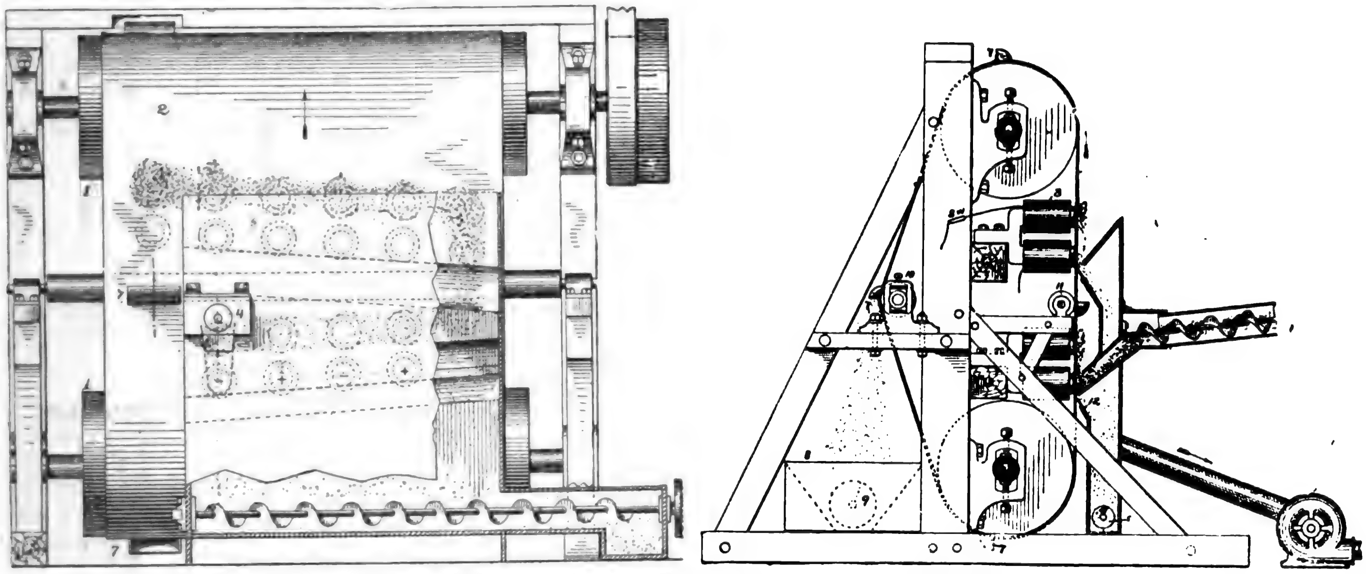
Instead of using solids for the expansible body, Mr. Edison has also employed liquids, the expansion being produced by hot water or steam passed through copper pipes coiled in a chamber or cylinder in which the liquid is placed. The expansion and contraction of the liquid produce movements of a piston which is connected by its piston-rod with the keepers of the magnets.

THE EDISON-DICKSON MAGNETIC IRON ORE SEPARATOR.

THE separation of the magnetic particles from the gangue in magnetic iron ore presents no great difficulties when the iron particles to be separated are in the shape of grains or in larger masses; but when the iron is present in the form of exceedingly fine particles, surrounded by a large proportion of gangue, the usual methods are inadequate to separate the iron, and special means have to be adopted.

To meet such cases, Mr. Edison, in connection with Mr. Wm. K. L. Dickson, has designed the ore-separator which is illustrated in two views in the accompanying engravings.

The ore, finely pulverized and either wet or dry, is fed in a continuous stream by the conveyer to the magnetic field adjacent to the lower pole of the first of the series of magnets shown, which are arranged with opposite poles adjacent. The iron particles are strongly attracted by the pole and tend to remain in the magnetic field. The heavy and loose non-magnetic material falls by gravity on the plate 12, and thence into the receptacle provided therefor. The continuous movement of the belt 2 tends to carry the iron particles away from the lower pole to the upper pole, and when the field of the first mentioned pole becomes overloaded the iron particles gradually work over to the upper pole, and in a short time the field adjacent to the upper pole also becomes loaded. The moving belt tends in the same way to raise the material away from this upper pole. At the same time the attraction of the magnet and the attraction of gravity force it back into the field.



FIGS. 1 AND 2.—EDISON-DICKSON MAGNETIC ORE SEPARATOR.

In this way the iron particles associated with and adhering to the gangue are beaten about and turned over and over and rubbed together in the magnetic field. This action allows the free foreign matter to drop, and at the same time loosens material which may adhere with considerable force to the iron particles. In a short time, in the operation of the machine, the field of the first magnet becomes loaded, and the magnetic material is slowly drawn by the adjacent pole of the next magnet to itself, thereby partially unloading the first magnet. The materials receive over this second magnet the same shaking and agitation as described in connection with the first magnet, and when the second magnet becomes overloaded it yields its load to the third magnet, where the operation is repeated, and so on through the series. The iron by the time it reaches the last magnet is practically free from the gangue, and is taken by means of the pockets shown, into receptacles provided for the purpose.

In the actual operation of the machine very little iron

gathers over the lower pole of the magnets, owing largely to the fact that the moving belt or cylinder tends to carry the material to the upper pole and away from the lower pole.

SCOTT'S FLASH SIGNALING LANTERN.

This lantern is the invention of Commander Percy Scott, R. N., and has been designed with a view to enable signals to be sent on the Morse system with greater rapidity than has heretofore been possible, and from a point where the present mechanical arrangement of shutter could not well be employed.

The lamp is surrounded by a number of vertical shutters pivoted above and below, and engaging by means of short arms or toothed wheels with a central wheel. The motion of the latter is produced by an electro-magnet acting against the force of springs; when the magnet is energized a rapid but short movement of the wheel takes place, opening the shutters for a longer or shorter period, as desired, and produces thereby longer or shorter flashes of light. The action of the springs carries the wheel back to its original position as soon as the current is broken in the electro-magnet. The electrical circuits are arranged in a special manner with the view of avoiding running the lamp at full incandescence during such time as the shutters are closed, and consequently the light is obscured. The magnet coils are, therefore, put in circuit with the lamp, the resistance of the former acting so as to dull the incandescence, but only to such a point as will allow the thick filament necessary for the 100 c. p. lamp employed to be raised to its full incandescence during the period of the shortest flash which may be found possible to use in practical working.

In order to further reduce the strain put upon the lamp by the heat developed during continuous running, a special switch is employed in connection with this lantern. The handle of the switch is hinged in such a way that under

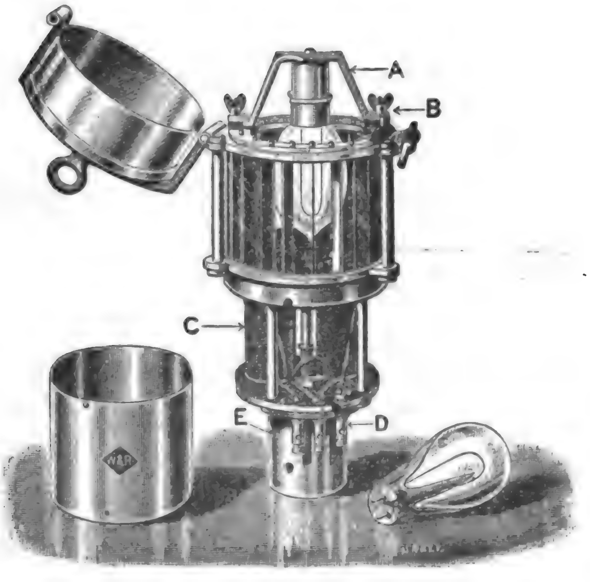


Fig. 1.—Scott Signaling Lantern.

normal conditions a strong string is pulled upon the end of it and breaks the main circuit to the lantern.

In order to commence signaling it is necessary to pull down the handle against the force of the spring; this completes the circuit to the lantern, and a further depression operates the telegraph key controlling the shutters. The contacts are so arranged that in the act of opening the shutters the lamp and magnet circuits are momentarily in shunt to one another, and as the E. M. F. absorbed by the magnet coils is only eight volts, the amount of sparking during signaling is very small. Extra contacts are attached to the switch to enable a Morse instrument to be added whereby the signals may be automatically recorded in the same way as in telegraphy. The action of the lantern is very satisfactory, and one of the original type has been in work for several months on board H. M. S. "Northumberland."

Our two illustrations show both the lantern with its shutters open, as is the case when no current is flowing, and also with its cover and tube removed to show the inner details. At A is shown the form of holder adopted, which, by unscrewing the fly nuts, B, enables the lamp to be at once removed for the substitution of a new one; at C are the two magnet coils, actuating the armature; and at D are three terminals respectively joined to the magnet

Fig. 2.—Scott Signaling Lantern.

coils, the lamp and one dynamo terminal. The framework supporting the shutters is complete in itself, so as to be removable in the case of any repairs being necessary to this very important part of the mechanism. E is a stout tube enabling the lantern to be fixed on the top of a mast, to which it is pinned through the hole seen in the side. It may equally well be suspended from the ring attached to the cover.

It is hoped that by means of this lantern it may be possible to attain to such speed in flash signaling that the two parties may be able to interpret each other's signals, which at present, owing to the different rates at which the signals are sent, is found to be very difficult.

The work in connection with this lantern has been entrusted to Woodhouse & Rawson, United, Limited, of London, the well known electrical engineers. This lantern can, of course, be used for signaling by the merchant marine, and on any ship fitted with the electric light.

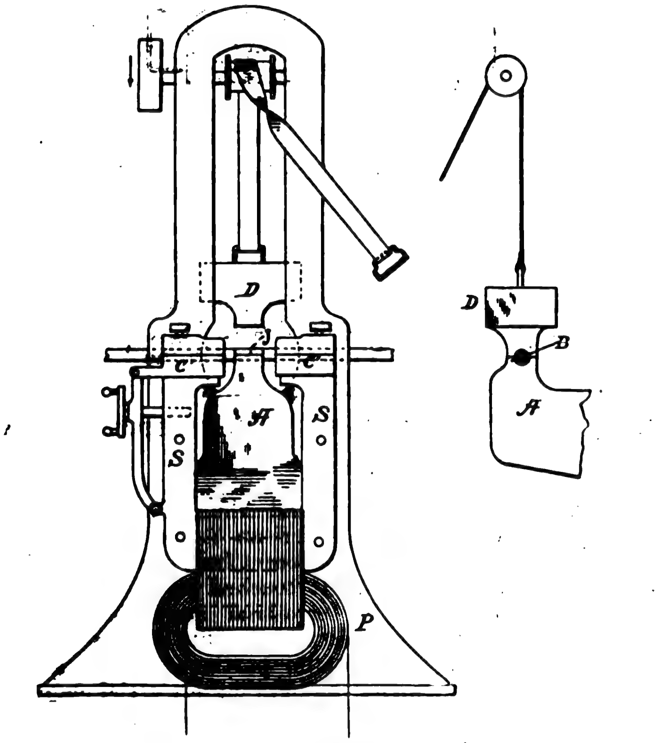
IN FAVOR OF ELECTRIC ROADS.

The *Boston Advertiser* presents interesting and important information as to the working of electricity in connection with street cars in several cities of the Union. The testimony thus obtained is almost invariably in its favor. The result is encouraging, of course, to the public of Boston, in which the system is established, and is likely to remain. There are special difficulties attending it here, from the fact that a portion of our streets in which it is used are narrower and more crossed than in most of the other places, yet in the severe test which overhead electric wires are undergoing this week there has been a gratifying success, as far as safety is concerned, and we have strong hopes that it may be continued. The *Advertiser's* survey comprehends cities in all quarters, and the uniformity of the intelligence that comes from them is remarkable.—*Boston Herald.*

ELECTRIC WELDING IN CONNECTION WITH THE DROP PRESS.

It is but a few weeks since that we drew attention to a variety of interesting developments in the application of electric welding to the working of metals, and now are again able to note a further application devised by Prof. Thomson. In this latest work Prof. Thomson has, as it were, combined his electric welding apparatus with a drop press in the ingenious manner illustrated in the accompanying engravings, Figs. 1 and 2, which are so clear as to need no further description.

The operation of the combination is exceedingly simple. When the pieces are to be welded under the drop, the drop D, is raised and sustained in an elevated position. The bars, B B′, are put into the clamps, slightly clearing the lower anvil, A, and abutted fairly well. The current is put on while the pieces are being pressed together at the joint, J, and gradually the joint attains a welding heat, as well as a section of the bars on each side of the joint. At this moment the drop is allowed to fall and completes the work,



Figs. 1 and 2.—Thomson's Combined Electric Welder and Drop Press.

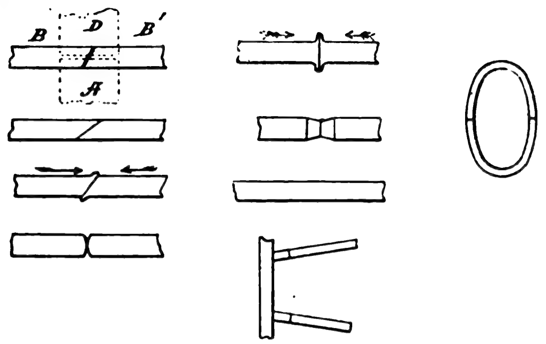
after which the welded piece is removed for the insertion of others.

One of the ways of preparing the ends of the pieces is shown in Fig. 3, the two ends being slightly scarfed or tapered before welding between the drop and the anvil. It is found that this preparation, which is shown in a still more exaggerated form in Fig. 4, produces a partial lap and a partial butt-weld of very great strength and uniformity.

Fig. 5 shows how the pieces are pressed together when they become plastic and before the descent of the drop. They tend to ride up a little one upon the other on account of the slanting surfaces. As soon as the welding heat is reached the descent of the drop welds and completes the joint.

For butt-welding the pieces are prepared with a rounded surface, as in Fig. 6, placed in contact and afterward pushed up to form a burr or expansion, Fig. 7, before dropping. It is advisable, however, in welding not to form too great an expansion of this kind, and it is also desirable that the clamps, C C′, one or the other, be movable toward the other when the drop comes down, so that the metal may spread endwise during the formation or shaping of the bar. This latter precaution may be entirely obviated by striking the pieces when they have attained, from the shapes shown in Fig. 6, a partial butt-weld, indicated in Fig. 8, a slight depression existing around the joint or metal section, which, when the drop descends, is completely filled up with the hot and plastic metal at the welding temperature, so as to give a finished and smooth surface, as in Fig. 9.

By making the surface of the drop and anvil more com-



Figs. 3 to 11.—Samples of Electric Welding and Drop Forgings.

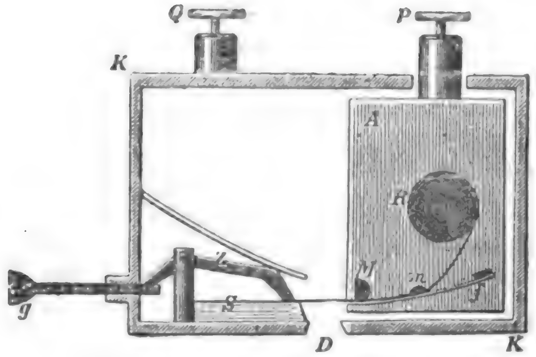
plicated in outline, almost any form of work may be accomplished. Thus two joints, Fig. 10, may be made and finished in one operation, and in making a chain-link of two of the pieces, Fig. 11, both joints may be struck at one operation into the desired form.

Although designed more particularly to effect the electric welding of separate pieces, it is also well adapted to the making of drop-forgings.

THE SIEMENS-VIOLLE STANDARD LAMP.[1]

BY DR. E. LIEBENTHAL.

The forms up to the present suggested for obtaining the unit of light passed by the Paris Congress have all of them many inconveniences, being both difficult to manage and most of them costly. That illustrated in the accompanying figure has been specially designed to overcome these difficulties. A stand some 4 in. high carries a box, K K, shown full size in the figure. On the bottom of the box is



The Siemens-Violle Standard Lamp.

an insulated metal plate, A, on which is a small drum of platinum strip, R, a movable half cylinder, *m*, a larger fixed one, M, and a terminal, P. The strip passes under M and *m*, against which it is pressed by the spring, *f*, and thence to the plate, S, where it is clamped by the claw, Z. The strip is now stretched by turning *m* backwards, and on passing a current through the instrument the platinum strip is melted, the light being observed through the aperture, D. The handle, *g*, is now pressed, pushing S and Z forward, and at the same time lifting Z. On pulling *g* back, Z falls again, clipping the end of the platinum, and drawing on a fresh piece for the next reading.

1. *Elektrotechnische Zeitschrift.*

The lamp does not absolutely fulfill the requirements of the Congress, as the source of light is platinum just melted, instead of melted platinum on the point of solidification; but, if it should be found necessary, a correction factor may be ascertained once for all. The cost is infinitesimal compared to that of the original standard, one gramme of platinum, costing about 65 cents, being sufficient for 50 readings. The metal is also obtained pure without difficulty, as there is, of course, no fouling due to the source of heat.

Preliminary trials with the lamp showed several small defects in the means of making contact on the right-hand side; these, however, were overcome by covering M with platinum, and abolishing *m* altogether, the strip being tightened by manipulating *g*. It was found also that more or less tension had but very slight effect on the results obtained. The current used varied from nine amperes to as much as double, due to variation in the gauge of platinum supplied. The strip used was about 5.5 mm. broad and .011 mm. (.44 mils.) thick. A very large number of comparisons were made against the amylacetate standard, the current being slowly augmented, and the grease-pot carrier slid along the photometer bar as the light increased, the point at which the carrier stood when the coil fused being taken as the reading. The results obtained do not agree perfectly among themselves, the mean error in 180 readings being 2.9 per cent., whereas the same observer made two amylacetate lamps agree within 0.95 per cent. The errors are attributed both to variation of the platinum standard itself, and also to the fact that just before

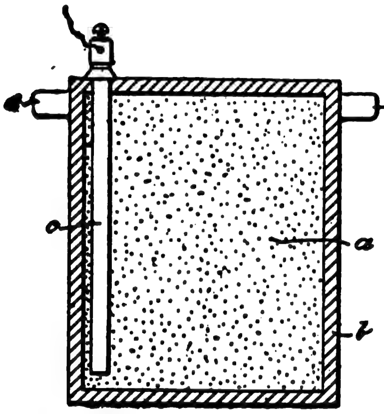


FIG. 1.—HOLLINGSHEAD'S SECONDARY BATTERY PLATE.

melting the light is considerably whiter than the amyl standard.

As the final result Dr. Liebenthal gives the value of the amylacetate standard as .569 Congress unit.

Herr v. Siemens originally gave the figure as 0.7 legal unit, but thought that this was probably too high, owing to impurities in the platinum.

From previous experiments the value of the English standard candle had been found to be 1.169 that of the amylacetate lamp, which makes the legal value of the candle .665 legal unit. On the other hand, M. Violle himself has made the value .54, a difference of over 20 per cent.

In conclusion Dr. Liebenthal says that owing to the color the platinum lamp is best suited for arc-light determinations, and recommends that the platinum should only be about .2 to .3 mils thick.

HOLLINGSHEAD'S SECONDARY BATTERY PLATE.

THE reduction in the weight of storage batteries has, for obvious reasons, been one of the chief aims of those engaged in their construction, and various methods have been employed to attain that end. Among others, we may note the construction in which all vestige of the usual grid has been removed, the active plate consisting merely of a compressed mass of lead oxide. This form, however, has been open to the objection that crumbling takes place in time as the battery is worked; and, hence, to avoid this, and still obviate the necessity of using a metal grid, Mr. W. B. Hollingshead, of Bronxville, N. Y., has designed the type of plate shown in the accompanying engravings. This plate, as shown in Figs. 1 and 2, consists of the active material, *a*, such as red lead or black oxide of manganese, inclosed in a crust, *b*, of porous material and having a car-

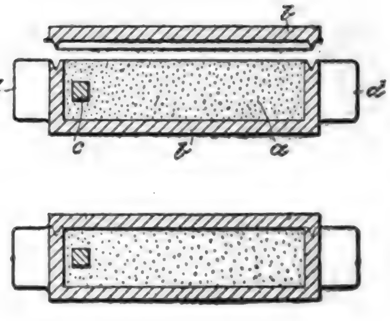

FIG. 2.—HOLLINGSHEAD'S SECONDARY BATTERY PLATE.

bon or other conductor, *c*, connecting with it through the crust.

Mr. Hollingshead makes the crust of plastic kaolin in two parts, and then incloses the material and joins the edges of the parts in the manner shown in Figs. 2 and 3, after which he bakes the crust and produces the porous condition. The crust is provided with lugs, *d*, projecting from the sides, for suspending the plate in the jar.

ELECTRICITY AT THE AMERICAN ASSOCIATION.

BY PROF. H. S. CARHART.

THE address of Prof. Cleveland Abbe, vice-president of the Physics section of the American Association for the Advancement of Science, at the recent Indianapolis meeting, was on Terrestrial Physics. It touched upon the obscure question of the origin of terrestrial magnetism. Prof. Abbe concludes from the low permeability of iron at high temperatures that the metallic portions of the earth's interior cannot be magnetized, and that terrestrial magnetization must be restricted to the earth's shell or crust. He therefore inclines to the theory of magnetism derived from terrestrial currents in planes at right angles to the axis of rotation. He reasons that the earth is immersed in a dielectric, and is placed in some kind of electrical field due to solar radiation. If this were the case it would require no inconsiderable currents round the globe as a solenoid to produce the known terrestrial magnetism, since the cause operating to prevent permanent magnetism in the earth's interior would also prevent such material from serving as the core of an electro-magnet.

In the physical section Prof. Mendenhall presented facts, derived from the magnetic observations of the Coast and Geodetic Survey, going to show that magnetographs often record earthquake disturbances, not as mechanical shocks, but as magnetic perturbations. These he conceives to be due to the sudden stresses to which the earth is subjected in earthquakes; and these stresses modify the earth's magnetism. In support of this view he showed, from an analysis of the photographic records of magnetographs, that two diurnal fluctuations in declination depend upon lunar action; and he ascribes these to the stresses in the earth's crust produced by the same forces which raise the tides. The subject will be pursued further by observers of the Geodetic Survey.

Prof. Nipher, of St. Louis, described a new method of

measuring the electrical resistance of liquids, such as the internal resistance of a battery. It consists briefly in placing the resistance to be measured in one arm of a bridge with a two-part commutator to effect rapid reversals of the current through the electrolyte. From measurements thus far made the results are found to agree with those of approved methods to within one per cent.

Mr. E. G. Merritt described the peculiar behavior of a galvanometer when used with a thermopile. It consists in small periodic pauses in the deflection of the needle when the thermopile is exposed to a steady source of heat radiation.

These pauses, which may even amount to reversals in the motion of the needle, for a short distance, are always equidistant in time; and the first maximum bears a definite ratio to the total deflection which the needle will reach if the radiation upon the face of the pile be continued indefinitely. Comparisons of different sources of radiant heat may, therefore, be made by observations of the first maxima occurring at the first pauses of the needle. The phenomenon was shown to be due to the composition of a damped vibration of the needle, and a deflection produced by an E. M. F., the law of variation of which may be expressed by an exponential curve. The paper was an admirable example of a short investigation completely worked out.

Sections A, B, C, and D of the Association spent one day by invitation at Terre Haute and held sessions in the Rose Polytechnic Institute. An elegant dinner was served at the Terre Haute House to the 200 guests, and Col. R. W. Thompson, ex-secretary of the Navy, made the address of welcome. Col. Thompson welcomed the Association to the same place nineteen years ago. He excited lively interest by his vivid narrative of experience with Morse and of his efforts to secure a $25,000 appropriation from Congress to construct an experimental telegraph line. In this connection he said that one of his colleagues was subsequently defeated for Congress because his constituents disapproved of his vote for the appropriation for the telegraph. What a commentary on the righteous judgment of the people!

Many members took occasion during the meeting to ride on the electric railway in Indianapolis. It works admirably; and the central line of iron poles, carrying the wires, is an ornament to the street rather than a disfigurement. A large party accepted the kind invitation of the Parry Manufacturing Co. to visit their factory for the purpose of witnessing electric welding on a commercial scale. They saw a single workman welding wagon tires at the rate of about three per minute. Two men were engaged in welding inch axles also, and both operations were conducted with the most gratifying success. The process is very satisfactory to the manufacturers, and its rapid introduction into large plants is assured.

The papers presented to the physics sections of the Association included a relatively smaller number on electrical topics this year than for several meetings. Other departments of physics received a larger share of attention than usual. The papers were of a high average, but none reached the highest water mark.

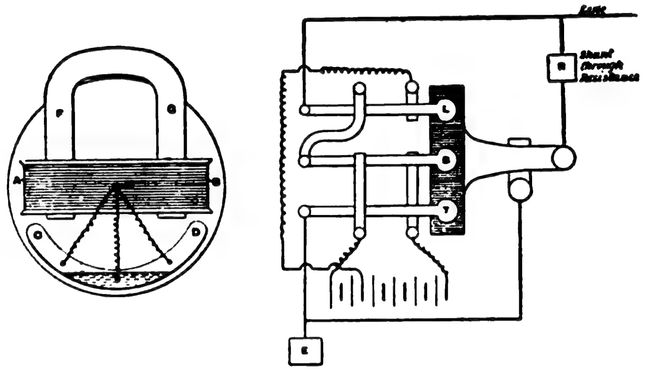
LOCAL INTERESTS IMPROVED BY ELECTRICITY.

Electricity is doing more for the country towns, says the *Pittsburgh Dispatch*, than all other agencies combined. It is lighting villages that would otherwise be groping in the dark, for gas corporations do not settle in such places. The game is not big enough. But the greatest thing electricity is doing for the small towns is the running of the street cars. This has given them a forward impetus that has been of immense benefit to all of their business interests. A great deal of the vim and push seen in Western Pennsylvania towns is due to electricity.

THE new state of Washington is a pretty lively place. There is no lack of enterprise within it. The towns of the state are rapidly adopting electricity for lighting and motive power purposes. The electric lighting company of New Whatcom has decided upon the Westinghouse alternate current system and will immediately install a 750 light plant.

THE BAROTHERMOTELEMETER.[1]

THIS instrument, the invention of Mr. Johnston Stephen and the Lord Justice Clerk, is designed for the purpose of enabling observers to take readings as often as desired, and by a single wire, from barometers and thermometers placed at great heights or distances, without the necessity of the observer being resident where the instruments are placed, thereby saving much expense, and enabling observations to be taken at points where residence might be impossible. The barometer has inserted in its mercury a rod of insulating material, on which a screw thread has been cut, and on this thread a fine wire is wound. An electric circuit established through this coiled wire to the mercury, and by a conductor from the mercury to earth, will, of course, meet with more or less resistance, according to the height of the barometer, as the coils are more or less short-circuited by the mercury. The thermometer has two carbon threads passed down into the mercury, and in the same way as in the case of the barometer, the resistance is increased or reduced by the fall or rise of the mercury lengthening or



FIGS. 1 AND 2.—THE BAROTHERMOTELEMETER.

shortening the circuit through the carbon threads. The procedure by the observer at a receiving station consists in taking, first, a reading of the line resistance, without passing the current through the instruments, then passing the current through the instruments in succession, and taking readings, correcting these by the reading of the line wire.

The mode in which these changes are accomplished is shown in Fig. 1. The flat coil A B is balanced on the pivot E, and the permanent fixed magnet F G rests within the coil. On the circular disc to which A B is attached, a curved tube C D is placed, which has a metal plate along its lower side, and a small quantity of mercury (shown by the shading). Three wires are inserted in the upper side of the tube, one in the centre, and one near each end. When the tube C D is at rest a weak current passed from the line through the centre wire will not disturb the position of C D. The line resistance can thus be noted. If a strong + current be then passed, C D is moved so that the mercury leaves the centre wire and makes contact with one of the side wires, and thus shunts the circuit from the line through the barometer circuit, the resistance of which is then checked. The thermometer is then checked by passing a strong — current, which turns C D in the opposite direction, and makes the circuit through the other side wire. The mode in which these switchings are accomplished at the observing station is shown in Fig. 2. It will be seen that when the key L is used a weak current passes to line; when the key B is used a strong + current passes, and when the key T is used a strong — current passes. In each case when the key is still further depressed it gives the current an alternative path through a bridge and proportional coils, thus enabling the readings of the resistance to be taken. The upper side of the large key which connects the rheostat is covered with insulating material to prevent short-circuiting.

1. *Industries.*

ELECTRICITY AS APPLIED TO THE EXTINGUISHING OF FIRES.[1]

BY H. L. LUFKIN.

To speak of electricity as even a possible agent in the extinguishing of fires would seem absurd if we look for our information only in the daily press, which would lead one to believe that the mode or form of motion known as electricity was potent only as an incendiary to instigate conflagration and death. You will readily concede that of all the elements in nature none possesses so wide a range of applicability as electricity. Since its first commercial use by Cook and Wheatstone in their railway telegraph in 1836 and 1838, followed by Morse in 1844, its development has been simply wonderful, especially in the past fifteen years. In the telegraph it is made to convey intelligible characters; in the telephone, articulate sounds; with it metals may be welded, light produced, power distributed, metals deposited by electrolysis, surgical operations performed by electro-cautery; nervous systems are toned up by galvanism and faradism; our street cars are operated by it, and our steam roads will soon follow; it pumps the organ in our churches, it runs the sewing machine in household and factory, it mines our coal and hauls it out, and why, I may ask, should it not be applied to the extinguishing of fires? Surely it is to-day an important factor in that direction, for does it not with wonderful intelligence advise you not only of the first manifestation of a fire, but of its exact location by means of the automatic fire alarm? Let us go a step further and cause it also to turn the water on and thus extinguish the fire.

Retrospection in this application of electricity shows us an almost undeveloped field. There has been some work done in the line of electric motors applied to pumps for domestic water supply where the city pressure is insufficient for all domestic requirements; also in the application of electric motors and pumps for supplying water under pressure for hydraulic elevators. As applied to fire department uses, there have been devised a number of electric motors and pumps, or electric pumping engines on trucks, which may be hauled about as the present fire engines are. This involves the necessity of a convenient place for connection with the electric light or power wires of a city at, or near, each fire hydrant, and also involves the maintenance of an expensive complement of horses, as in the present system. The pumping capacity, also, of any portable engine is of necessity limited to a weight and construction which can be readily hauled by a pair of horses with reasonable speed over the varying grades of a city. This at times is a serious matter in cities where heavy grades are frequent, especially in the winter time when streets are obstructed by snow, ice, etc. Prompt response to an alarm is, of course, a necessity, and involves the driving through crowded streets at a speed which is, certainly to the uninitiated, frightful, though singularly free from accident.

In lieu of these portable pumping engines and their several more or less objectionable features, I would submit for your consideration a system of stationary pumping engines, the operation of which I trust I may be able to make clear to you with the aid of these diagrams:

Let me first call your attention to the diagram, Fig. 1, illustrating a stationary system of water distribution for fire purposes under electrical control.

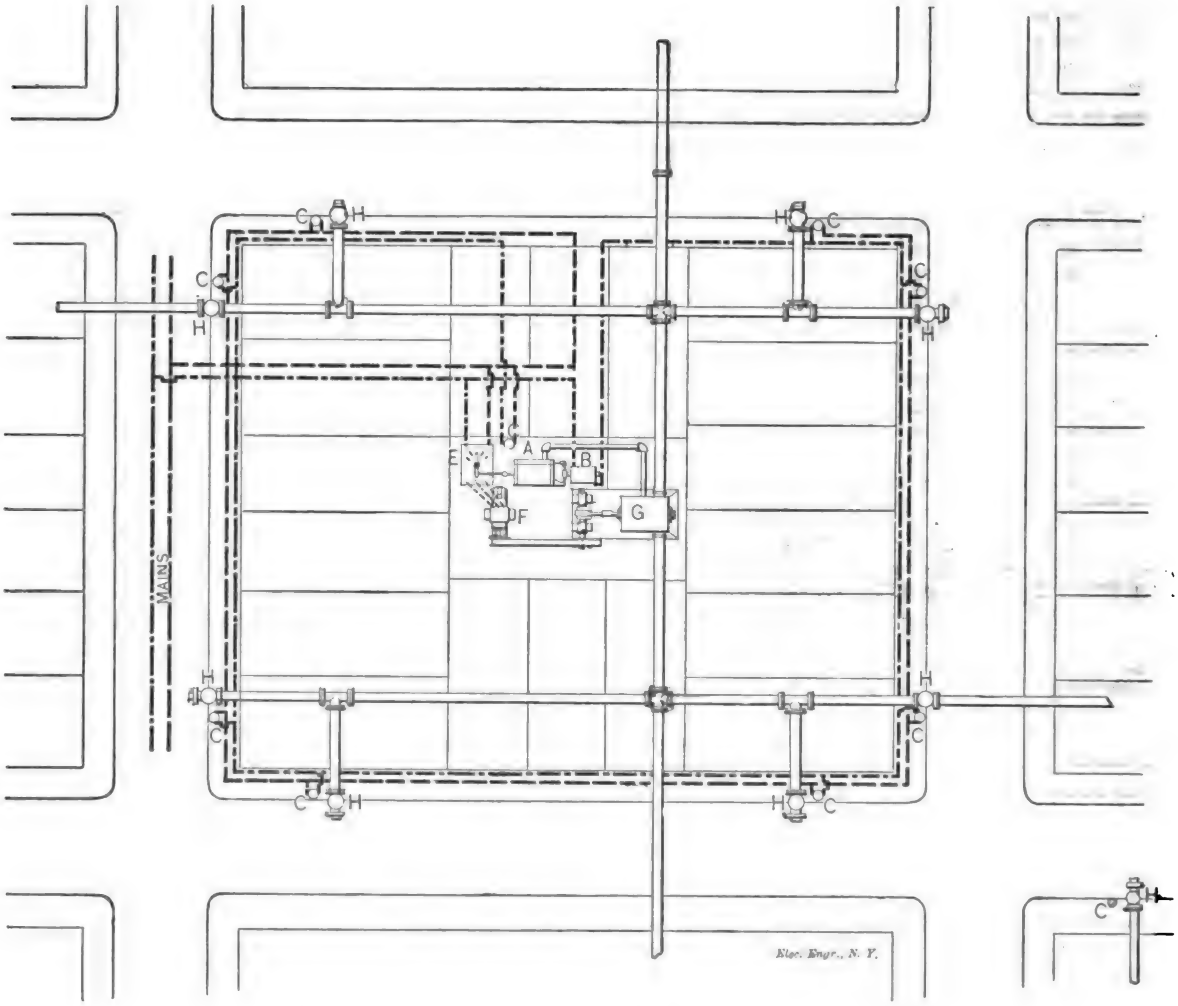


FIG. 1.—LUFKIN'S METHOD OF ELECTRIC FIRE EXTINGUISHING.

In this diagram A represents a hydraulic piston, the valves of which are controlled by the electro-magnet, B, the circuit through the magnet, and, therefore, the piston valves, being controlled by the switches, C C C, etc.

E represents a starting box or rheostat in circuit with the electric motor, F, which is connected by belt or gear to the pump, G. Radiating from the pump, G, is a system of piping connecting to hydrants or plugs, H H H, etc.

The diagram here shown is supposed to represent a city block or square. The pumping apparatus is represented in the centre of the block, though it is obvious that it may be placed in any convenient location which may be available and where it will be out of reach of frost, the system of piping being provided with a draw-off valve near the pump so that the system may be completely drained, if necessary, after use.

The operation of this system is as follows: The hose carriage,

1. A paper read before the Firemen's Convention, Detroit, Mich., Aug. 20, 1889.

with its complement of men, drives up to any of the fire plugs; the hose being attached, the switch, C, is turned. This operates through the magnet, B, and the piston, A, to throw over the switch on the starting box, and thus immediately throws the motor and pump into action. Each district would, of course, be provided with its motorneer, who would attend all fires in his district and care for the motor, pump, etc., during the fire, and whose duty it should also be to daily inspect the apparatus in his district to see that it is kept in proper repair. The motors would in these cases be connected to the mains of some company supplying electricity for light or power, whose charge for this service should certainly be merely nominal.

The water could be drawn from a city supply or from an independent supply provided for fire purposes only. The capacity of these stationary plants also may be equal to the capacity of ten or fifteen engines, if necessary, and the motor so connected to the pump that the pressure would remain the same on the system, whether only one stream or the full capacity of the plant were called for. These stations could also be made to cover a considerable territory, if desirable, and the several districts included in a general system could be connected together with suitable valves between them so that they could be operated separately, or together, as the exigencies of the fire might demand.

A plant of this character, with a capacity of 200 h., p., which would be capable of delivering about 2,500 to 3,000 gallons of water per minute, or, say, 165,000 gallons per hour, against 150 pounds pressure, could be set up and piped to cover quite a number of city blocks, say 10 or 15, at an expense of $20,000. The cost to operate this plant at its full capacity would not exceed $10 per hour, or, at the rate of 16,500 gallons of water for every $1 of cost. When the fire is out the cost stops absolutely. The wear and tear expense on a large plant of this kind should not be as great as on a single steam fire engine, to say nothing of the cost of maintaining horses and harness.

With this reference to a possible application of electricity to a pumping system for fire department uses, let us see what can be done in the way of protecting isolated buildings. The automatic sprinkler has become a familiar sight in many of our large stores and warehouses, and the reduction in insurance rates wherever these sprinklers are applied is ample evidence of their value. A modification of the system as at present applied suggests itself to me in the use of a motor and pump in place of the roof tank at present in use. The blowing out of a thermostat or other device which now brings the sprinkler into operation could also be made to start a motor and pump, and thus furnish a practically inexhaustible supply of water in place of the limited tank supply now in use. There are, however, numerous recorded instances where these automatic sprinklers have been "too previous," if I may be allowed the expression. In this connection I would ask your consideration of the diagram, Fig. 2, which illustrates a sprinkler system, which, while not automatic in its action, possesses some features of advantage over the automatic system, especially in stores or warehouses which are constantly patrolled, and therefore under surveillance. In this system the pump G and motor F are controlled by the same devices of piston A and magnet B as the system previously described. Connected to the pump and distributed through the several rooms or apartments to be protected, is the system of sprinkler piping H. On each floor, or in each department, if desirable, is situated a valve in a branch from the main piping, controlling the sprinkler system of the floor or apartment. This valve is controlled by a piston A and magnet B, similar to the ones controlling the motor and pump. The several magnets in the building are independently in series with the motor magnet. On each floor, or in any number of places on the floor, are convenient push buttons or switches, C, which, being closed, act to start the motor and pump and at the same time open the valve in any apartment connected with the switch closed. Where desirable, a second system of switches might be arranged which would act to stop the motor and pump and close the valves.

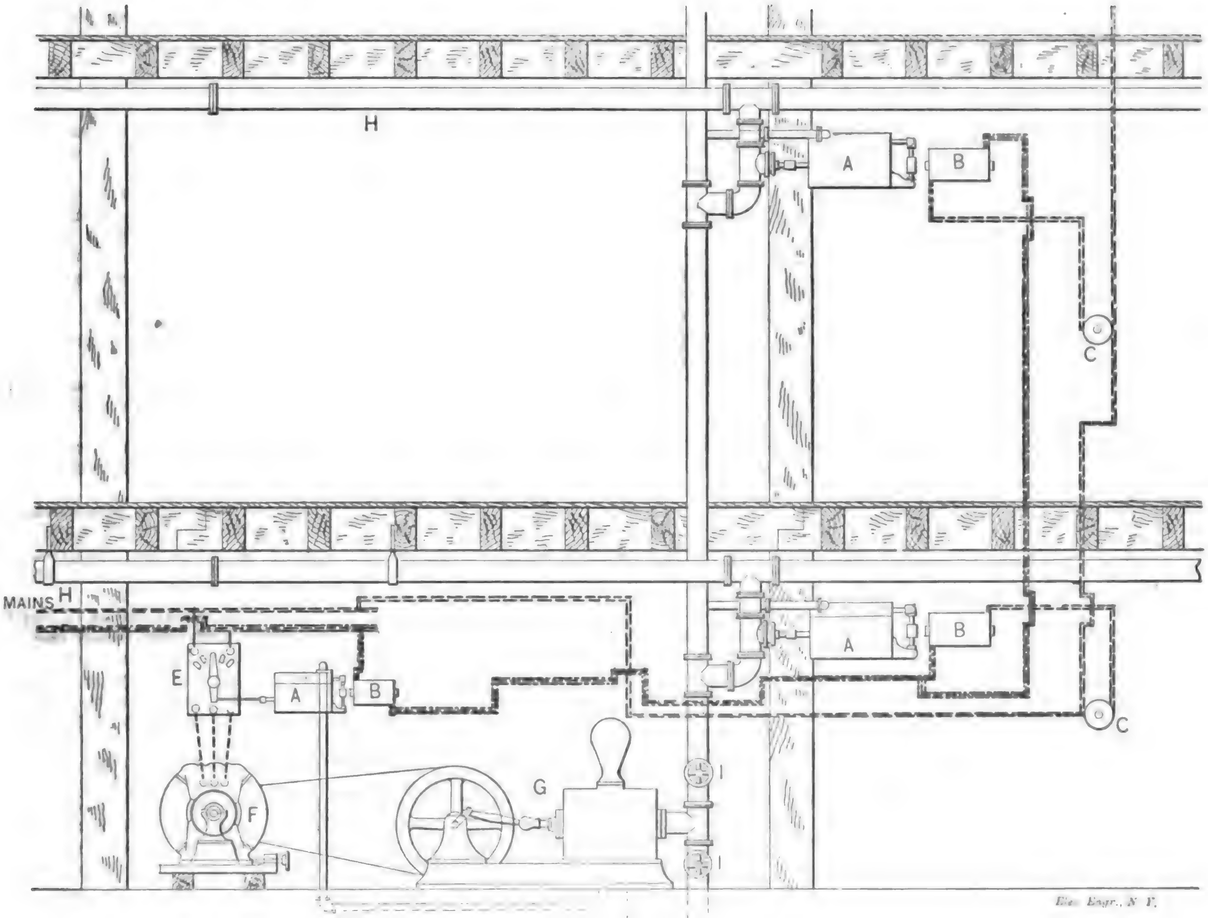

Fig. 2.—Lufkin's Method of Electric Fire Extinguishing.

It seems to me that in a theatre a system of this description would be particularly desirable. There could be located in any number of places about the theatre sets of switches controlling the entire house. On the discovery of a fire in one of the dressing-rooms the sprinkler could be started in the room from any of these several switch boards or in the room itself. In this manner, also, the exits and lobbies could be literally flooded, and thus allow of the harmless escape of the audience, even should the fire practically surround them.

These are some of the possibilities of electricity as applied to the extinguishing of fires, and I submit that, while electricity is making such giant strides in the mechanic arts, its inevitable application as a power for the operation of fire department apparatus is by no means a remote possibility, but will be found an actual necessity.

ELECTROLYTIC THEORIES.[1]

BY PROFESSOR G. F. FITZGERALD, F.R.S.

Electrolysis has been explained on two different theories by Grotthüs and Clausius. As generally received they differ. Grotthüs' theory, as generally given, assumes that the molecules in an electrolyte are both polarized and moved by the electric forces within the liquid. This seems so far untenable that it would appear that double the electric force would double both the polarization and the motion of the molecules, and so should produce four times the electrolysis. The objection, however, assumes that we know the causes resisting the motion, and with proper, and not very improbable, assumptions as to the resistance to motion depending on it and on the polarization, a linear relation between current and electromotive force, *i. e.*, obedience to Ohm's law, seems possible. A modification of Grotthüs' hypothesis in the direction of Clausius' is, however, possible. Suppose that when polarized the molecules *drew one another apart* at a rate proportional to the polarization. This at once makes the relation between electric force and the decomposition a linear one, and so satisfies Ohm's law in the case of small currents. It also so far agrees with Clausius' hypothesis that it explains electrolysis and double decomposition as properties of the same kind. The molecules in a liquid will occasionally be arranged by accident in the proper polarized condition in a closed circuit for drawing one another apart; and if the circuit includes molecules of different kinds, there will result double decomposition. There seem to be very serious difficulties in supposing that uncombined atoms are for any finite time free in the liquid; and the supposition that it is a particular arrangement that is required before exchanges take place and that with this arrangement exchanges take place of their own accord, seems to explain electrolysis and double decomposition without supposing free atoms to exist within the liquid. I have not assumed Prof. Armstrong's suggestion that the proper arrangement for double decomposition is a double molecule; but it seems a likely hypothesis, and one that should be investigated from the chemical, rather than the physical, side.

There are some other phenomena that have been explained upon the supposition that free atoms are gadding about in a liquid. Such are the lowering of the boiling and freezing points by solution of salts, and their effect on osmotic pressure. If dissociated atoms are going about in a liquid as in a gas, it seems impossible but that they must diffuse at different rates; and that this is not observed seems conclusive against the hypothesis, no matter what else the hypothesis may explain. Consider solution simply. Why does chloride of sodium dissolve in water? There must be some strong affinity between the two of a chemical or semi-chemical nature to break up the cohesion of the crystal; and it seems reasonable to assume that this same affinity keeps the molecules of NaCl moving about among the water molecules, so that they diffuse about. Now if the forces drawing them about be independent of the nature of the molecule, most of the phenomena explained by gaseous laws are explained. Pressure of a gas depends, at any temperature, on the number of molecules, and not on their kind. This is Avogadro's law, by which molecular weights are calculated; and if the forces drawing a molecule about in a liquid are independent of the kind of molecule, the very same law of pressure would hold, the pressure forward of molecules of different kinds would depend on their number only, and in the same way as Avogadro's law would enable molecular weights to be calculated. In this connection it is well to state that some bodies may, nevertheless, be much better able to produce pressure than others, because of their being more easily polarized, *i. e.*, turned into an effective direction. A molecule which could be easily turned into an effective direction would be about twice as effective as a molecule which went about in a higgledy-piggledy way; and one would consequently expect electrolytes to produce more, nearly double, the osmotic pressure that other bodies did. As to the changes of boiling and freezing points, they seem explicable by exactly the same hypothesis. The reduction of vapor pressure by molecular affinity of dissolved salt would depend only on the number of molecules of salt if all salts have the same molecular affinity for water; and the same would apply to the change in freezing point. Hence all these phenomena are explained without assuming free atoms, and they are all explained by what can hardly avoid being a *vera causa*, namely, whatever affinities they are that cause solution, which latter is an unexplained phenomenon on the dissociation hypothesis. That it is reasonable to think that the forces keeping the molecules of salt moving about in the water are independent of the nature of the salt, appears from various considerations. In the first place, these forces are in all probability due to the residual affinities of the non-metallic elements. These same forces are probably the cause of crystallization. These are old suggestions. That these residual affinities should be nearly the same for different combinations does not seem at all unlikely.

If a rather shaky argument in favor of its likelihood on mechanical grounds is desired, the following may deserve attention. Suppose a molecule of NaCl, for instance, at rest, or nearly so, in a crystal. Subject it to this affinity. Its velocity, after it has gone a distance, s, will be given by some such relation as $f\, s = \frac{1}{2}\, m\, v^2$. Now, for the sake of temperature equilibrium, with molecules of somewhat similar structure, $\frac{1}{2}\, m\, v^2$ must be the same in all. It seems likely that, at least approximately, the kinetic energy of motion is proportional to the total energy, and that this is the same for each molecular group; if so, the kinetic energy must be approximately the same for different groups. Now, with very dilute solutions s must be nearly the same for different molecules, and if so we get that for temperature equilibrum f must be independent of the nature of the molecule. How this equalization of f for different kinds of molecules comes about may be as follows: Molecules in a liquid move about among one another, but are well within the sphere of one another's attraction, as is evidenced by superficial tension and by the tension to which a liquid can be subject. A very small change in the distance apart of the molecules means, however, a very great change in the forces between them, as otherwise they would be extensible and compressible like gases. It seems likely, then, that when a salt dissolves in a liquid it requires for temperature equilibrium that the distances of the molecules should change by the very small amount required in order that f may become the same for all substances. The very minute change in distance would not sensibly affect s.

1 Communicated to the London *Electrician* by the Secretaries of the Electrolysis Committee of the British Association.

AN UNKNOWN PHILOSOPHER—GAULARD.[1]

BY EMILE GAUTIER.

Under the presidency of Alessandro Volta—a name of destiny—there has just been organized in Italy a club of engineers and scientists who have voluntarily assumed the pious work of organizing a subscription with the view of erecting a statue to the French electrician, Lucien Gaulard.

This act in itself was nothing particularly astonishing.

It was simply natural that the Italians should make a duty and an honor of paying this posthumous tribute of admiration to our countryman and moulding him in bronze, for the sufficient reason that in 1884 he exploited before their eyes and on their account the marvellous discovery of which they had the first fruits.

What, on the contrary, is astonishing, is that they have been permitted to make the start.

But it is chiefly in France that it is true to say "No one is a prophet in his own country." Often it is not even enough to die in order to obtain justice.

Such precisely is the case with poor Gaulard, of whom, I would bet heavily, not nine Frenchmen in a hundred knew even his name.

And notwithstanding all, this illustrious unknown has revolutionized electricity. Not only has he conceived but also *effected* one of the most prodigious industrial miracles of the closing days of the present century, and were History just, it is by the side of Edison that she would legitimately place him.

Is it not to him, in fact, that the entire honor of the first distribution of electric light over great distances really belongs?

It was at Lanzo, upon exactly the same site where the commemorative monument dedicated to his memory by the gratitude of strangers will be erected, that six years ago, at the time of the International Electrical Congress of Turin, the place was unconsciously consecrated by his genius.

Thanks to the apparatus that bears his name (associated with that of only one other—an Englishman—from whom he could always find encouragement and support); thanks to the transformers of Gaulard and Gibbs, of which the technical description would be too long and dry to be set forth here, and whose value needs no demonstration, he succeeded there *upon a circuit of* 80 *kilometres* in feeding 112 electric lamps of the most different systems with the incredible delivery of more than 90 per cent. efficiency.

Never before had an equal distribution of light been made.

The experiment caused a great sensation everywhere, and it was to Gaulard that the jury of the congress, composed of delegates from the academies of the entire world, decreed, without hesitation, the international prize of 10,000 francs, with the "grand gold medal."

This did not prevent, four years later, the unfortunate great man, whose unpardonable crime was that of not being either a magnate or a "*struggle-for-lifer*," from dying at the age of thirty-eight, in the full flower of his maturity, at the Hospital of Sainte Anne, hopeless, insane, his brain exhausted by the fermentation of bitterness.

It was just the moment when, by the cruel irony of fate, his invention took a development that even in his most ambitious dreams, he had never dared to anticipate.

Destiny sometimes has these atrocious refinements of cruelty. Perhaps it is necessary, that, like all new deities, the fairy Electricity should also have her martyrs.

At this very hour one hundred thousand horse-power maintain

1. *Revue de France.*

one million lamps by the use of the methods created by Lucien Gaulard.

In London the single station of Grovesnor Gallery, equipped on this system, generates the current for 40,000 lamps over a circuit of 120 kilometres. It is to the same apparatus that on the other side of the Atlantic, the Westinghouse Company owes its capacity to light 150 American cities.

Here in France, in revenge—excepting only the city of Tours—the invention of the unhappy innovator is nowhere yet in operation.

You see that the transformers (secondary generators) of Gaulard and Gibbs will not be acclimated in France, although everywhere else; that is to say, not until they commence—for progress is never stopped—to be out of date and to grow old.

Not even in his own country does Gaulard receive the tardy reparation made to such other misunderstood geniuses as Denis Papin, Philippe Le Bon, Nicolas LeBlanc, Sauvage, Millet, and "tutti quanti," who were all unable to win the prize at the game of distributive injustice, or to learn the taste of the heady wine of triumph. While the names, infamous forever, of Gabrielle Bompard and Michel Eyraud are now in every mouth, the ignorant, forgetful and skeptical crowd has still to ask with sneering lips, what will rhyme with the echoless name of Gaulard, which not a single municipal council has dreamed of giving to the smallest street.

It will not be on his native soil but in the land of exile—the only hospitality, as it seems, for unrecognized talent—that the "outlaw" will have his statue, to which, perhaps, there will not a single Frenchman be found to have contributed.

Ah! the brutal proverb is right, "No one is a prophet in his own country"—above all when that country is called France.

THE LONDON AND PARIS TELEPHONE CABLE.

Telephonic communication between London and Paris is now merely awaiting the consent of the French Government. Mr. Preece stated at the Newcastle meeting of the British Association that experiments had been made to ascertain under what circumstances such communication was possible; and in February, 1887, he communicated to the Royal Society a paper in which it was stated that, taking the resistance of a conductor in ohms, and its capacity in microfarads, telephonic communication is good, when the product of these is 5,000; when it is 10,000 talking is just possible, and the limit is reached at 15,000, when no articulation is audible. Experiments have been made with telephones on the cables between Dover and Calais, between Holyhead and Dublin, between South Wales and Wexford; and from the results of these, the officials of the Post Office are perfectly satisfied that they can build a line between the capitals of the two countries through which telephone communication will be not only possible, but highly satisfactory.

The present cable between Dover and Calais is quite unsuitable for the purpose, both on account of its high resistance and its capacity. The requisite details of the new cable and the land lines have been worked out, and the results of the calculations have been compared with the tests recently made upon a line from Baldock in Hertfordshire, through London to Worcester. In this experiment, which was conducted with the view of determining the constants of the proposed line to Paris, two copper wires were employed, and no less than 27 miles of the circuit was through the underground system of the postal telegraphs in London. The communication through this line by telephone was very good, and confirmed in a very satisfactory manner the calculations which have been made. The telegraphic communication between London and Paris has increased very considerably during the past few years; and as it is necessary to make some extensions, it has been considered that the new line should be one through which telephony could be carried on.

A MOVEMENT TO CONSOLIDATE THE CARBON INDUSTRIES.

RUMORS have been current as to new "deals" in the carbon industry, and it has been stated that the Thomson-Houston Company have secured control of the National Carbon Co. A recent report for Cleveland is as follows:

The National Carbon Company is established in a big brick building at the foot of Willson avenue. The officers are: President, H. W. Lawrence; secretary, H. E. Hackenburg; treasurer, Webb C. Hayes; superintendent, J. H. Osborn.

It is stated on the best of authority that the majority of the capital stock was sold to the Thomson-Houston Company several weeks ago. An outside estimate of the purchase price placed the amount at about $150,000. Messrs. Lawrence and Hayes retain financial interests and an active connection with the business.

The Standard Carbon Company, which has been much sought by the Thomson-Houston Company, has a large plant at Hamilton street and the Cleveland and Pittsburgh Railway. The officers of the company are: President, Hon. D. A. Dangler; vice-president, J. B. Crouse; secretary and treasurer, W. G. Smith; superintendent, H. A. Tremaine.

The authorized capital of the company is $500,000, but of that amount only $150,000 has been issued. Several conferences have been held between Mr. Dangler and representatives of the Thomson-Houston Company, but they have been unable to agree upon terms. Negotiations have now been suspended temporarily, but it is not unlikely that they will be resumed and that the plant will pass to the Eastern company. They were anxious to secure the property and proposed to retain Mr. Crouse and Mr. Smith. Mr. Dangler would be too busy with his other interests to take part in the management if the plant was secured by the men from the East. The chief argument of the Thomson-Houston people was that with the plant in the charge of their company one-quarter of the stock would be nearly as valuable as the whole under independent management. It was shown that the company would practically control electric lighting, and would, therefore, be the main consumer of the carbon points. The companies established in the various cities would have a natural inclination to buy supplies from the parent company, it was said, and the various factories would naturally experience a boom.

There are four carbon manufactories in Cleveland, the Brush Electric, National, Standard and the Globe. Those four concerns manufacture 60 per cent., or 54,000,000 of the 90,000,000 carbons used annually in the United States. A factory owned by the Thomson-Houston Company, at Fremont, turns out ten per cent. of the total production, but it is usually accounted a part of Cleveland, and that city is given credit for 70 per cent. It is said that the output of the Globe Company is about 5,000,000 carbons yearly. There are two factories in St. Louis and one in Pittsburgh. For years the Brush Company stood at the head of the business, but other companies entered the field, and during the rapid development of the business they secured important positions. From the time of the introduction of electric lighting, however, Cleveland has been in the lead and has practically controlled the production.

MANUFACTURE OF VERMILLION BY ELECTROLYSIS.

In a wooden vat, one metre in diameter and two metres deep, circular plates 15 centimetres wide are placed against the sides, and on these the mercury is exposed, one centimetre deep. These plates are connected with the positive pole of a dynamo. At the bottom of the vat is a sheet of copper electroplated with iron, and connected with the negative pole. The vat is filled with a solution of 8 per cent. of nitrate of ammonia, and 8 per cent. of nitrate of soda. A worm, pierced with holes, supplies a constant and regulated current of sulphuric acid; the excess of gas escapes by a tube projecting from the lid. A screw agitator keeps up a thorough mixture in all parts of the liquid. When the current passes it immediately forms a precipitate of red sulphide of mercury. Attempts have been made to dispense with the current of sulphuric acid by making up the bath with:—Water, 100 litres; nitrate of ammonia, 8 kilos; nitrate of soda, 8 kilos; sulphide of soda, 8 kilos; sulphur, 8 kilos. Under these conditions one need only add sulphur and mercury to extract at the end of the operation vermillion which rivals that which can be obtained by sulphate of ammonia.

LAYING OCEAN CABLES.

Herbert Laws Webb—a nephew of Mr. W. H. Preece, F.R.S., the Chief Electrician of the British Postal Telegraphs, and a son of F. C. Webb, C.E., who was one of the pioneers in sub-marine cable engineering—will contribute to the September number of *Scribner's Magazine* a most interesting article entitled "With a Cable Expedition," which describes (in the form of a personal narrative of an expedition in which he took part) the whole process of laying a deep-sea cable—the life on ship-board among the very original men who form the expert staff in such work, the curious machines devised expressly for cable laying, the great ocean surveys, in which submarine islands and mountains are discovered, the excitement of a break, and the weary disappointment of grappling for the lost cable. The pictures are from photographs made on the cable ship "Dacia," of the Silvertown Company, expressly for this magazine. Mr. Webb is now electrician on the staff of the Metropolitan Telephone Company, in this city.

ELECTRIC RAILROAD EARNINGS AT WINSTON, N. C.

A very interesting statement comes to hand of the earnings at Winston, N. C., of the Sprague road in that town. The road has been in full operation for more than a month without any charge for repairs. The road now has three cars running and shows an average income of $68.76 per day, or nearly 1400 passengers per day for the three cars. The average car mileage is 114 miles per day.

CONNECTICUT MOTOR CO.—At a special meeting of the stockholders of the Connecticut Motor Co., it was voted to increase the capital stock from $30,000 to $40,000, the present stockholders to be given the preference in subscribing for the increase until Oct. 1.

CORRESPONDENCE.

CHICAGO.

The Calumet Electric Lighting Co.—A New Electrical Factory.—Electric Railways at Springfield, Ill.—A High Efficiency Incandescent Lamp.

THE Calumet Electric Lighting Company, of which F. H. Watriss is the president, have asked for and obtained a permit from the Department of Public Works to erect poles and place electric lights on all streets from Eighty-seventh to One Hundred and Sixth, in South Chicago, the company having obtained an ordinance from that village before it was annexed to Chicago.

Rumors are current that some prominent men in electrical circles of Chicago and vicinity are about to start a new Western enterprise, and contemplate the erection of a large factory for the manufacture of small electrical specialties on an extensive scale, in Oaklawn, which is one of the South Side outlying suburbs of Chicago.

Electric street railway matters are receiving considerable attention just now in Springfield, Ill., and the Springfield City Railroad Company had a big time recently in opening their new extension to South Springfield. All the citizens are up in arms with the electric company against the Board of Aldermen and City Council, and say they will have tracks placed on any street in the city they please, in spite of the aldermen. This decisive action in favor of a corporation who have risen above horses and mules shows the strong favor in which electrical rapid transit is held by the public.

The question of obtaining lamps of higher voltage, greater efficiency and increased life, is one of the most important in the electrical industry. An extraordinary advance in these features is claimed for a new lamp which will shortly be placed upon the market, and which is now being tested for the inventors by the National Engineering Bureau of Chicago. A life test has been commenced of the new lamp, which, it is stated, absorbs in no instance more than 2 watts per candle in the small sizes, the larger sizes being even more efficient. A 300 candle power lamp has been burning with an efficiency of 1¾ watts per candle, which brings it into direct comparison with arc lamps for efficiency. Commercially successful lamps of 200 volts can be made. A comparative test is now progressing on a 50 volt circuit, and the statement is made that this new lamp is only using nine-tenths of an ampere, whilst the least amount of current absorbed by any of the others is 1.06 amperes, the candle power measured on the photometer being the same in all cases. The lamps on this test have now been running 200 hours without the slightest depreciation in the appearance of the new lamp. In taking the readings three different style of ammeters and voltmeters are employed, and the readings are noted by the managing engineers of the bureau and several responsible college professors. It is needless to say that if these lamps fulfil in practice the claims which are made for them, they will work many changes in the present methods of distribution of incandescent lighting.

CHICAGO, Aug. 23, 1890.

The Lincoln Park Electric Fountain.—Rapid Transit Schemes.—Fire Alarm Telegraph Litigation.

THE electric fountain at Lincoln Park, which was presented to the Lincoln Park commissioners and dedicated to the people of Chicago by Mr. Yerkes, is now completed and in regular operation. It is patterned after the great prismatic fountain which was one of the leading attractions of the recent Paris Exposition, but is said to be larger and capable of producing even grander and more striking effects. It will run between the hours of 8 and 10 o'clock with slight intermissions. The working of the fountain is pronounced quite a success and is a magnificent sight. The jet and spray effects are very numerous and effective. Underneath the fountain is a cellar in which the electric light plant is situated. As the streams spout, rays of light play in the same direction as the streams. There are all the colors of the rainbow, sometimes all turned on together, and sometimes the jets are all of the same hue. Red, green, violet, blue and pure white are seen in succession, and then all together. The white and green tints suggest an ordinary waterfall under a strong light. The whole fountain is a masterpiece of ingenuity and a most imposing and appropriate structure, adding considerably to the attractions of the park.

An incendiary fire occurred at McVicker's Theatre, about 2:30 A. M., Tuesday morning last. The building was completely gutted and all but the outer walls are in ruins. This theatre was very extensively equipped with electric lighting and some of the scenic effects gotten up in various productions by its agency have been remarkably striking. The big building, however, is to rise immediately Phœnix like from its ashes, and will be beautified and improved in every possible way, and electric lighting and electric motors for cooling, ventilating, and power purposes will play no mean part in these innovations.

Among the new rapid transit schemes now in contemplation in Chicago is the Chicago and Jefferson Urban Transit Company, which has just been incorporated at Springfield, to build and operate lines of street railway in the city of Chicago and neighboring towns, which are to be run by electric or other motor power, and it is to be sincerely hoped, both on account of good service and financial reasons, that no other power than electricity will be employed for suburban transit of the class required. The capital stock is $1,000,000, and the incorporators are John Johnston, Jr., Henry Vannatta, Frank H. Dickey, Frank H. Baker, Thomas P. Keefe, Charles B. Hosmer and Edward D. Hosmer. One of the above incorporators states that the company will start work within a few weeks. It is proposed to run a line of cars through the towns of Almira, Hermosa, Cragin and Galewood, beginning at North and Arlington avenues; also a line on Grand avenue, running northwest to the end of the old city limits. The decision with regard to motive power has not yet been made.

A bill has been filed in the United States Circuit Court, to restrain the city of Aurora, Ill., from infringing improvements in non-interfering fire alarm boxes by the Gamewell Fire Alarm Telegraph Company, of New York. The original patent was issued to Joseph W. Stover, Feb. 14th, 1882, and was assigned to complainant in May last.

CHICAGO, August 30, 1890.

PITTSBURGH.

Electric Railway Notes.—Tower and Mast Arm Lighting.

THE Squirrel Hill Railway Company, of this city, which recently fell into the hands of a receiver, is to be provided with means for the completion of its line. The receiver has just asked permission of the court to borrow five thousand dollars to apply to the work, and this has been granted. There is still a snag in the way, however. As laid out, the Squirrel Hill line encroaches on the domain of the new Schenley Park, and the city is disposed to object very vigorously to this encroachment. A slight change will probably have to take place in the route.

At first, the people of Allegheny were pretty well pleased with their new tower system of electric lighting, but recently there have been a good many complaints to the effect that the illumination is not evenly distributed. The City Council has decided to make an addition to the equipment in the shape of ten towers and one hundred mast arms. It is thought that once these new towers and arms get in use, the dark places of the city will be few.

The Dravosburg, Mendelssohn and Elizabeth Electric Street Railway Company was chartered at Harrisburg, Pa., a few days since. This company will operate an electric line seven miles in length, which will run between the three towns whose names appear in the company's title. The capital of the concern is forty-five thousand dollars. The directors, who are all residents of McKeesport, Pa., are James E. White, John Haben, John K. Skelley, James L. Devenney and Joseph A. Skelley.

The Pittsburgh Traction Company, operating the cable system between Pittsburgh and East Liberty, and the Duquesne Traction Co., which is constructing an electric line between Pittsburgh, East Liberty and Wilkinsburg, bid fair to become active rivals. The Pittsburgh Company is said to have determined to reduce its five cent fare to three cents so soon as the Duquesne Company shall be in position to compete. The lines are parallel for a considerable portion of the distance between Pittsburgh and East Liberty. The Duquesne Company says that there is business enough for both lines at a reasonable price, and it looks with some distrust on the reputed intention of the other company to come down to three cents. The feeling between the two companies seems to afford the public no cause for sorrow. It is altogether probable that should a three cent fare come, it will be received with good grace by the patrons of the line.

The new Pittsburgh incline railway which runs from South Twelfth street, Pittsburgh, to the summit of Mount Washington, has just been put in operation. This incline is equipped in the best possible fashion both as to machinery and cars. The engines are of the most approved kind and the cars are in every way convenient and comfortable. This incline is to be run in connection with the electric line of the Birmingham Traction Company.

The East End Electric Light Company, of this city, is enjoying great prosperity. The demand for light in the district covered by the company is steadily growing, and hence it is necessary to make frequent additions to the lines and dynamo capacity. Otherwise, the East End Company would be paying big dividends.

PITTSBURGH, Aug. 23, 1890.

Mr. Byllesby's Return.—Electric Railway Work.—Lighting at McKeesport and Washington.

VICE-PRESIDENT and General Manager H. M. Byllesby, of the Westinghouse Electric and Manufacturing Company, returned on the steamer Majestic last week from Europe, where he has been superintending the erection of the branch works of his company in London.

The borough council of Washington, Pa., has advertised for bids to light the streets of the town by electricity. This contract is now in the hands of a natural gas company, but that corporation refuses to supply that illuminant any longer because it is wasted too much.

A new switch board is being put up in the power house of the Pleasant Valley Electric Railway Company, which is said to be quite a unique affair, there being no other of its kind in the country. The "board" consists of brick and terra cotta lumber covered with cement, a composition which greatly eliminates any fear of fire.

The McKeesport Light Company is contemplating many improvements and enlargements at its plant in McKeesport. The station has apparatus of 2,000 lights capacity, and the company expects to double the plant within the next six months.

Two Pittsburgh lads are just now reveling in the idea that they have invented an electrical device which will supersede the present system of overhead trolley wires. The lads are only twenty years of age and it is to be hoped that their ardor will not be cooled off too soon. The invention consists of a series of iron boxes buried in the ground along the car tracks, at a distance of a car's length. Then there is an iron rod or beam attached beneath the truck of the car in a manner so as to slide over the tops of the iron boxes. By this means they expect to establish connection for the current. The boys have applied for a patent.

PITTSBURGH, Aug. 30, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.

EFFICIENCY OF TRANSFORMERS.

[136.]—In the August 6 issue of your paper I see a criticism of Prof. Ryan's and Messrs. Humphrey and Powell's papers on the efficiency of transformers. Having worked in the same line, theoretically and practically, in reading these classical papers I was very much interested to find experimental proof of the different phenomena I tried to deal with by mathematical methods. And I was all the more glad to see Mr. Swinburne's elucidating remarks on those papers, although I cannot agree with him. Thus, for instance, he says in his letter, that "with no Foucault-currents, the maximum primary current on open circuit necessarily corresponds with the zero of the E. M. F.," and because, in the diagrams given in the papers mentioned above, the difference of phase between primary current and E. M. F. is shown less than 90°, he thinks these curves look inaccurate.

Now, first it is a questionable matter to refute empirical data by mere theoretical reasoning; and then we can prove, in a very simple manner, whether this assertion is true. Suppose Mr. Swinburne's assertion were true, that the primary current on open secondary circuit reaches its maximum at the instant when the E. M. F. is zero; then this is certainly true also for the simplest harmonic wave of the E. M. F., which is following the sine law. But when we leave out of consideration the influence of hysteresis—and we can very well imagine a transformer, which contains no iron, and therefore has no hysteresis—then it is obvious, and can be shown by a simple analytical reasoning (which I omit here, having given it elsewhere [1]), that the electric current follows the sine law, too, no matter whether it produces secondary and Foucault currents or not. According to Mr. Swinburne's assertion the difference of phases between current and E. M. F. = 90°; therefore the energy consumed by the current is:

$$W = \frac{E\,C}{2}\cos 90^\circ = 0.$$

Where E = maximum E. M. F., C = maximum current.

But, nevertheless, this current produces heat, that is, energy, and we would have, therefore, a production of energy without consumption—that is, *perpetual motion!*

In reality, for a sine-wave of E. M. F. which meets no Foucault currents, and can be represented by the equation:

$$e = E \sin \frac{2\,\pi\,t}{T},$$

where E is the maximum E. M. F., and T the time of one period, the current is given by:

$$c = C \sin\left(\frac{2\,\pi\,t}{T} - \omega\right),$$

where:

$$\tan\omega = \frac{2\,\pi\,n^2\,10^{-8}}{\rho\,R\,T}$$

and:

$$C = \frac{E}{\sqrt{R^2 + \frac{4\,\pi^2\,n^4\,10^{-16}}{\rho^2\,T^2}}}$$

where:

R = electric resistance,
ρ = magnetic "
n = number of primary turns.

ω is therefore always $> 0^\circ$ and $< 90^\circ$, but approaches 90° the more, the smaller ρ is: that is, the better the magnetic circuit of the transformer is, but can never reach 90°.

That means "*the maximum of current must necessarily occur before* the E. M. F. reaches zero." This is proved by the figures given in the above mentioned papers.

Secondary and Foucault currents advance the phases of the primary current, and thereby decrease this angle of lag ω still more, because also drawing energy from the primary source.

Furthermore, I cannot see that the Foucault current curve must be similar to the primary current curve, as Mr. Swinburne says. According to my notions the Foucault currents are due to electromotive forces, set up by the changes of the magnetism in the iron and the other conducting parts of the transformer, exactly in the same manner as the secondary E. M. F. is produced in the secondary circuit. Indeed, they are true secondary currents, and the only difference between them and the secondary current proper is, that they cannot (yet) be used.

Hence they must have the shape *not* of the primary current, but of the secondary E. M. F., with only those differences which are due to their different positions in the magnetic field, and the different amount of magnetic leakage they meet with.

Therefore, they must be expected to lag behind the primary current by more than 90° and less than 180°, and this angle of lag must be greater or smaller, according to the greater or smaller amount of secondary and Foucault currents induced.

That the Foucault currents sometimes give back energy to the primary circuit, I cannot find astonishing either, knowing that the secondary currents do so, and that the Foucault currents are only a special kind of secondary current.

As regards the assumption, made by Prof. Ryan, that the electric resistance of an incandescent lamp for *continuous currents* is the same as for *alternate currents of the same effective value*, although I do not believe this to be absolutely correct, it is certainly so nearly true, that the error caused by it must be much beyond the limits of sensitiveness of our instruments. A very interesting mathematical treatment of this question, especially relating to the Cardew voltmeter, by Dr. C. Cranz, can be found in the *Zeitschrift für Mathematik und Physik*, edited by Prof. Schloemilch, Dresden, Germany, volume 34, page 92.

CHARLES STEINMETZ.

YONKERS, N. Y.

THE DISTRIBUTION OF LIGHTS IN TEXTILE FACTORIES[1].

The lighting for textile industries is here considered, first, because there exists none other which has need of so powerful lights; and secondly, because it has been thoroughly studied in all its details, and since the type of factories is nearly the same in all countries, all of them may, therefore, be compared among themselves. The rooms are large, and they contain a certain number of similar machines. The walls and ceilings are assumed to be white. For spinning, the minimum number of lamps should be one 12-ampere arc for 180 to 200 square metres (say 230 square yards, or 15x15 yards). The maximum for a 9 or 10 ampere arc should be 80 to 100 square metres (say 110 square yards, or 10½ x 10½ yards). These areas are for high rooms and for spinning unbleached or clear colored yarn. For weaving, the minimum is a 12-ampere arc for 120 square metres (133 square yards, or 11½ yards square). For white, unbleached or clear colors, a good light is given with a 10-ampere arc over an area of 75 to 80 square metres (93 square yards, say 9½ yards square). But for black, and especially for dark colors, which must be distinguished thread by thread, some workers are not satisfied unless 10-ampere arcs are placed 7 metres (23 feet) from each other, that is 49 square metres (59 square yards) for each lamp. In general it is not advantageous to employ lamps of less than 8 or 9 amperes; 10 amperes gives a good light for industrial use. When the rooms are small, or the lighting is not evenly divided, 6 amperes may be used. For blacks and dark colors twice the amount of light must in general be used as for white or light goods, and even then the eye will be fatigued. In weaving light goods by glow lamps, a 10-candle and even an 8-candle lamp may be used for lighting

1. *L'Electricien.*

two looms for unbleached stuff, and, on the other hand, for colors, two 16 candle lamps to a loom; or, if it is rather long, two 20-candle lamps are needed. That is exceptional, but it may be said that in most cases one 16-candle lamp will suffice for two looms. For arc lighting it is not a question of the number of looms, but the area which has to be lighted; it is, in fact, a general illumination. The room must be lighted, and all that is in it, without troubling about any particular machine or part on which the worker is occupied. Arc lamps obviously cannot well be employed in small rooms. For outside work in courtyards and the railway goods yards, an excellent effect is produced by lamps of 15 amperes, placed at 12 metres (40ft.) high, or, in case of need, lamps at 12 amperes at 10 metres (33ft.) high; but it is not advisable to use less than this. These figures have been arrived at by practical experience in Belgium and Germany, and it is because they have been departed from in lighting the streets of Paris that the illumination there tires the eyes without making things properly visible. There is an unnecessary number of lamps placed too low, and of too feeble an intensity; moreover, this arrangement is more expensive.

FINANCIAL MARKET.

QUOTATIONS ON ELECTRICAL STOCKS.

Mr. F. Z. Maguire, Electrical Securities, of 18 Wall street, this city, reports the following quotations of August 29 from New York, Boston and Washington:—

REPORTS OF COMPANIES.

STOCKS AND BONDS.

MONROE, S. C., is to vote on the issuance of $25,000 of bonds for an electric light plant.

DENVER, COL.—Colwell, Johnson & Co., of Providence, R. I., are offering for sale $18,000 of the 6 per cent. bonds of the Denver Consolidated Electric Co.

CLINTON, MASS.—The capital stock of the Clinton (Mass.) Gas Light Company has been increased to $60,000, from $35,000, and the new issue was immediately disposed of at par—$500 per share. The money thus raised is to be expended in the construction and equipment of the Company's new electric light station now under way.

BROOKLYN, N. Y.—The Edison Company proposes to increase its capital stock from $600,000 to $1,500,000 and to build three new stations. The company is already supplying 20,000 lights, or twice as many as were expected within the first year of operation. The present stockholders will be permitted to subscribe for 9,000 shares at par, but 20 per cent will be repaid to them in the form of a dividend. No regular dividend has yet been declared, but the company is on a paying basis and the stock is selling at its full value.

MEMPHIS, TENN.—A dispatch from Memphis, Tenn., concerning the projected mammoth electrical railway system, says: "C. B. Holmes, of Chicago, to-day made the final payment of $537,000 necessary to close the deal and assume control of all the street car lines of Memphis." The entire street railway system of Memphis comprises some 65 miles of road.

NEW YORK CITY.—L. Fitzgerald, president of the Mercantile Trust Co., trustee, gives notice that on the 1st day of September, 1890, it will have the sum of twenty thousand dollars in the sinking fund provided for under a certain mortgage to it as trustee, dated May 24, 1888, and an agreement dated November 1, 1888, both executed by the Metropolitan Telephone and Telegraph Company, and it invites proposals for the sale to it of bonds secured by said mortgage at a price satisfactory to the Metropolitan Telephone and Telegraph Company, at a rate not exceeding par and ten per centum premium.

THE DALLAS (TEXAS) TRACTION CO. has filed a mortgage upon its property to the Fidelity and Safe Deposit Co., of Philadelphia, Pa., to secure bonds amounting to $1,250,000. A Philadelphia syndicate purchased recently for $750,000 a controlling interest in the stock of the Dallas Consolidated Street Railway Co. Out of this deal grew the Consolidated Traction Co., with $1,250,000 paid-up capital. They went immediately to work to issue thirty-year six per cent. bonds, as above, the proceeds to be spent in improving and extending the system. One of the first moves will be to change the entire system of road, being 25 miles in operation and several miles under construction, to electric power.

DIVIDENDS.

NEW YORK CITY.—Coupons of the 1st mortgage 5 per cent. bonds of the Edison Electric Illuminating Co. will be paid on and after Sept. 2.

ELECTIONS.

THE CONSOLIDATED ELECTRIC LIGHT CO., of New York, will hold its annual meeting on September 17 at 32 Nassau street. The transfer books close September 1.

INVENTORS' RECORD.

Patents issued Aug. 26.

Alarms and Signals:—*Non-Interfering Signal-Box*, W. E. Decraw, 434,922. *Electrical Watchman's Clock*, H. S. Park, 435,185. *Electric Alarm for Clocks*, W. H. Deane, 435,213.

Conductors, Conduits and Insulators:—*Insulator*, C. O. Muehlberg, 434,992. *Automatic Disconnector for Overhead Conductors*, A. L. Jonhston, 435,098.

Distribution:—*Means for Distributing Electric Energy*, S. Z. de Ferranti, 435,114. *Regulation of Electric-Arc Light Circuits*, D. Higham, re-issue, 11,108.

Dynamos and Motors:—*Dynamo-Electric Machine*, W. F. Collins, 435,015. *Generator for Electric-Engine Circuits*, C. J. Van Depoele, 435,261. *Contact-Brush for Dynamos*, E. Franklin, 435,296. *Automatic Current-Regulator*, R. Thury, 435,332.

Telegraphs:—*Telegraph Relay*, T. A. Edison, 434,585. *Recording Telegraph*, J. B. Odell, 434,880. *Printing Telegraph*, J. B. Odell, 434,881.

ELECTRIC LIGHT FIXTURES IN THE FIFTH AVENUE THEATRE.

Mr. H. C. Miner has just refurnished the Fifth Avenue Theatre and with his usual enterprise and judgment he has put in the electric light. The massive chandelier which hangs in the lofty dome of the theatre is one of the main ornaments of the house. It was built by I. P. Frink, of this city, and cost Mr. Miner $1,500. It measures thirty feet from the brass ball at the end of stem to the plate at the upper extremity of the stem, and weighs 800 pounds. It contains 262 lights, gas and electric. The gas burners are made to resemble candles. The electric lights are incandescent lamps. It is proposed to light the house by electricity, the gas being reserved for supplementary purposes in any very special illumination. The lights can be used finely for scenic display, as many effects can be obtained by colored combinations. The lower circle contains fifty-six gas and fifty-six electric lights. It is surmounted by a silvered glass reflector. The gas will be lighted by electricity, three wires connecting with lights at equal distances from each other in the circle. Above this circle and the reflector are ten clusters of lights, each made up of six gas burners surrounding three electric lamps. Six feet above this circle of clusters is still another of ten clusters, each made up of four gas lights surrounding two electric lights. The chandelier is richly ornamented with brass, and the stem and pipes are silvered over or bronzed. The chandelier can be raised and lowered at will.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

NEW WESTINGHOUSE PLANTS.

The Westinghouse Electric and Manufacturing Company is now occupied with the installation of a twenty-five light plant at Galveston, Texas.

The Westinghouse Electric and Manufacturing Company has received the contract for a five-hundred light alternate current apparatus from Traverse City, Michigan. The electric light company at that place has been operating the Westinghouse alternate current incandescent system for some time, but the demand for incandescent lighting has grown so rapidly that this increase has become very necessary.

The Sedalia Electric Light Company, of Sedalia, Mo., which has been operating an alternating current electric light plant of the Westinghouse system for over a year, is about to enlarge its capacity. The company has just contracted for 750-light alternating current apparatus with the Westinghouse Electric and Manufacturing Company. This will give the plant a total capacity of fifteen hundred lights.

A few days ago the Lansing and North Lansing Railway line, of Lansing, Michigan, commenced operation, and, according to all accounts, everything went off with the greatest success. This is a street car company which has adopted the Westinghouse electric railway system and the officials of the road are very hearty in their praise of the system. A gentleman who was present at the starting of the cars stated that, although the motor men were all green hands, the cars ran without a hitch and in a manner perfectly successful. The opening of the line was quite an event in Lansing.

THE INTERIOR CONDUIT AND INSULATION CO.

This remarkably pushing and successful company had a slight set back last week on account of a fire that broke out at 527–537 West Thirty-Fourth street, at midnight, in the room where they dry green tubing. President E. H. Johnson writes us as follows: —"In reply to your inquiries I would state that the fire which partially destroyed our factory on Tuesday night, Aug. 26th, started in our drying rooms, and, after burning many thousand feet of green or untreated underground tube and effecting the destruction of our underground curing apparatus, was checked, so that the output of underground conduits will only be temporarily restricted. Having kept our original factory in West Twenty-seventh street on Interior Conduit work, this branch of our business will not be interrupted, and, with the aid of additional temporary factory facilities secured in that neighborhood, we will be enabled to aid the underground department materially. The burned building will be immediately rebuilt and a new structure seven stories high will be added. This will more than double our present accomodations and enable us to keep pace with the extraordinary demand made upon us."

We have ourselves had the opportunity of visiting the scene of the fire, and have secured one or two sections of cured tube that had gone through the ordeal. Where they were picked up, wood and iron and stone have disintegrated in a confused mass, but the tube itself, though in a measure carbonized by the intense heat, is whole and hard, showing a wonderful quality of resistance and endurance. The company were working night and day at Thirty-fourth street to fill their underground conduit orders, but, as will have been noted, will now enjoy larger facilities for production than ever.

THE WESTERN ELECTRIC CO.

The Western Electric Co. have just issued a very handsome new general catalogue. It is replete throughout with fine illustrations, and ample space has been allowed to display each cut and its accompanying descriptive matter. It is printed throughout in a clear, prominent type, on fine paper. The first portion of the book is devoted to their lines of annunciators, bells, push-buttons, electric gas lighting apparatus, batteries and material for work of this class, and some very handsome and efficient designs of these supplies are contained therein, as well as new specialties. The well known Paterson cables, which have met with such universal adoption everywhere, are then described, and some neat forms of cable hangers and terminals for a large number of conductors. Considerable space is allotted to a very full description of their arc and incandescent lighting systems, dynamos—both arc and incandescent—switch-boards, measuring instruments and kindred appliances for installation work being especially beautifully portrayed in very fine wood-cuts. Telegraph instruments, electrical testing instruments, speaking tube supplies, line wire, insulators and all kinds of tools and appliances for wire work, together with tables relative to size, weight and other properties of wires, complete a book which contains quite a

fund of valuable and useful information, and one which is of the greatest use to intending purchasers. Every one interested in electrical matters should supply himself with a copy.

JAS. W. QUEEN & CO. AS ELECTRICAL INSTRUMENT BUILDERS.

ONE of the interesting facts brought out by the recent Convention at Cape May came somewhat in the nature of a surprise to most of the delegates and visitors. It was that the old house of Jas. W. Queen & Co. had, with a remarkable display of energy and activity, stepped boldly to the front as makers of American electrical instruments, and were trying to build up their business on a scientific basis, showing in each production the benefit of thorough skill and knowledge. Up to about two years ago, the firm were handlers only of other people's goods. Seeing the advantage and necessity of having trained labor in this branch, they secured the services of two college men, to whom were specially entrusted the expert elements and details of the business, which soon became considerable, not only in electrical but in general apparatus. These men were Mr. R O. Heinrich, from Lehigh University, and Mr. E. G. Willyoung, from Michigan University. The former returned recently to Lehigh as Instructor in Electrical Engineering, but Mr. Willyoung spent a year traveling about among the laboratories of the country, and then came home to assume the duties of expert in chief. He now has a large corps of assistants and devotes the whole of his time to the superintendence of the designing and manufacturing and the general expert work of the house—which includes, of course, a large amount of electrical engineering. It may be mentioned that Mr. Willyoung, after graduating from Michigan University, occupied during 1887-8 the position of Assistant in Physics, and gave the instruction in the first year's work in Laboratory Electricity. During that time he was associated very closely with Prof. H. S. Carhart, the well known electrician, in all his expert work. This statement will help to give an idea of the expert ability brought to bear upon its products by the house, and it should be added that Prof. Anthony, president of the American Institute of Electrical Engineers, is still associated with the house as Consulting Electrician and in charge of standardizing and calibration.

As evidence of the departure made by Jas. W. Queen & Co., we would state that at Cape May Mr. Willyoung exhibited a complete line of their standard resistance boxes and portable testing sets. These were very much admired. The Standard Resistance Boxes included No. 1 set, designed and calibrated by Prof. Wm. A. Anthony and used as ultimate standard by the Electrical Supply Co., Edison Lamp Co., Moses G. Farmer, and all the leading electrical laboratories in the country. It is calibrated up to $\frac{1}{50}$ per cent. in accuracy.

The "No. 2 set," or improved Post Office pattern of Wheatstone's bridge standard megohm box, is in ten divisions of 100,000 ohms each, these divisions being capable of any combination of series or multiple as desired; terminals all at extremities of corrugated rubber pillars, so as to secure highest insulation. This was designed by Mr. Willyoung; also standard 100,000 ohm box in ten divisions, capable of any combination of series or multiple; standard 100,000 ohm box in four divisions not capable of use other than alone or in series. They expect to complete shortly the series by the production of a 10,000 ohm box subdivided into coils of 2000 ohms and less, and a 5000 ohm box subdivided in the same general way.

Their portable testing sets were five in number. The best one has a capacity of measuring from .001 ohm to 10 megohms, and is provided with a fibre-suspended galvanometer, which may be removed and used separately if desired. The needle of the galvanometer is thrown out of place by simply closing the lid of the box. A number of these have lately been sold to the government. The other four were of the same general style but of less capacity, and do not allow of the independent use of the galvanometer.

The first one of the above series of testing sets and galvanometers combined was designed conjointly by Mr. Heinrich and Mr. Willyoung; the others of the series by Mr. Willyoung alone. They are all calibrated by Prof. Anthony.

The firm also showed a complete line of capacity and contact keys, all of their own manufacture, and of the most approved design.

A large line of galvanometers, including those of Sir Wm. Thomson and other European inventors was also shown, including a number of ammeters and voltmeters, notably those of Ayrton & Perry, for whom they are sole agents; a curiosity among these was one ammeter up to 600 amperes; Schuckert ammeters and voltmeters, and those of Hartmann & Braun, for whom they are also agents; also Carpentier ammeters and voltmeters. Much interest was shown in the improved design of magnetic vane instrument, designed by E. G. Willyoung and just brought out by Queen & Co. The improvement consists chiefly in the placing of the moving system in a very close air damper, so as to render the instrument considerably more dead beat. These instruments are now, it is explained, the cheapest and best station instruments made, and are used entirely by the Mather Electric Co. and very largely by the Edison and Brush companies. They are now making several large instruments of this type up to 400 amperes for the Edison Co., to be placed on the Sound steamer, "Plymouth." They are made in all ranges and sizes.

A portable photometer designed by Mr. Willyoung was also shown, specially intended for street work and lighting inspectors. It measures from 7 up to 2,000 c. p., and the whole thing packs up in a compass of 37 inches by 5¼ inches, cross section.

Queen & Co. are now working on several new specialties which will be brought out in the fall. One of these is a large photometer for electrical laboratories exclusively. Another is a new ohmmeter giving direct readings of resistances up to 2,000 ohms, to within ½ per cent. accuracy.

McDOUGALL ELECTRIC CO.

The McDougall Electric Co., of the *Times* building, this city, have for the past month been running their car experimentally on the Seventh Avenue division of the Broadway road. The system was fully described in THE ELECTRICAL ENGINEER of July 23. The power is conveyed from the single motor to one axle through a double spur gear transmission, the other axle not being used for propulsion. The gears are encased in removable shells, which retain the lubricant and exclude grit. The current for the car is furnished by Gibson storage batteries. The quickness with which the car can be got under full headway from dead rest is very noteworthy. No effect is shown by the motor in the way of strain; and the operation of the car at all speeds is smooth and noiseless. The motor is intended to be used for all purposes, including not only storage traction but overhead wire operation, stationary motor work, etc. Mr. McDougall's practical experience enables him to meet the many conditions of difficulty in a very successful manner.

NEW YORK ELECTRICAL MANUFACTURING CO.

Mr. A. Noll reports that the business of the company is brisk. They have received an order from the Perfection Switch Co. to manufacture 50,000 porcelain base single pole switches. They are also doing a rushing business in their Barriett motors, especially the neat little "baby" size which has just been brought out.

THE VULCANIZED FIBRE CO.

We have received from the above company, of 14 Dey street, a copy of their catalogue and price list. It is a very interesting publication, showing the great number of uses to which the fibre has been applied, not only in electricity but in all the arts. For electrical purposes, the fibre is usually furnished in strips 8 inches wide by 40 inches long, which permits of its being more densely rolled. The tubes are from 20 to 22 inches long.

EUREKA TEMPERED COPPER.

We have noted from time to time the use of Eureka tempered copper on dynamos and motors and have looked upon its use as an evidence of good judgment on the part of their builders. We are now glad to note its use on the new direct current machine of the National Electric Manufacturing Co., of Eau Claire. The commutator of this machine is made of tempered copper, which is found to answer admirably for the purpose.

ALFRED F. MOORE.

The new catalogue just issued by Alfred F. Moore, of Philadelphia, is a beauty. It has a very handsome cover in gold, and several of the pages are printed in colors showing exactly how the wires and cords look. The catalogue is very complete, giving sizes, prices, etc., and entering into a variety of details. All classes of insulated wires are enumerated, as well as a variety of superior cables.

ARMINGTON & SIMS ENGINE CO.

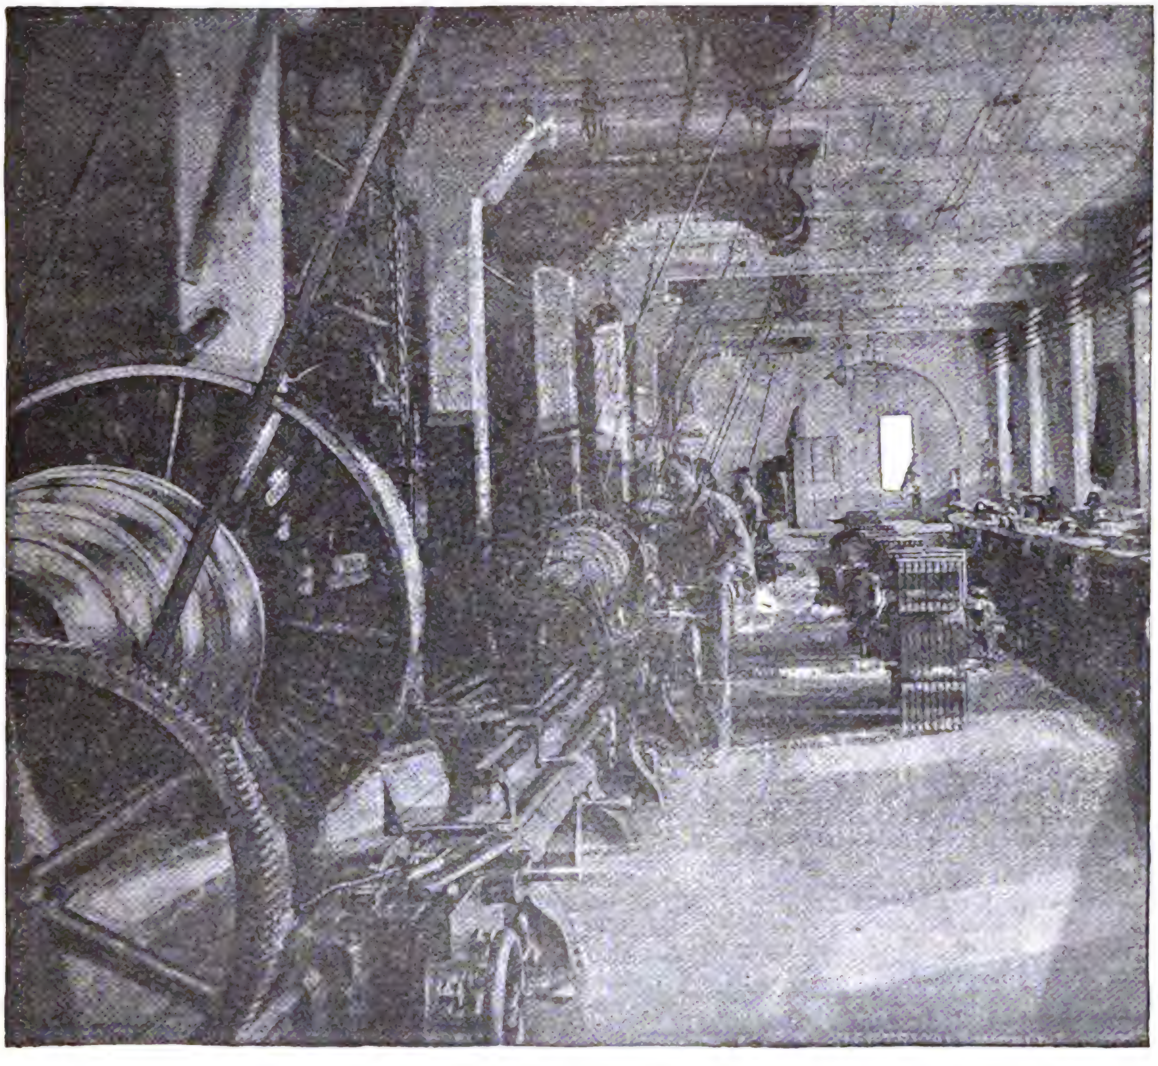
A handsome and well-deserved compliment has been paid by the people of Rhode Island to Mr. G. C. Sims in the proposition to run him as the Democratic candidate for Governor of the State. Writing on this subject, the Boston *Herald* says: "There comes the suggestion that the party could not find a better man to place at the head of its ticket this fall than Gardiner C. Sims. The suggestion is a good one. There could not be named a better, cleaner or more progressive man. He is of the people, a self-made man, a practical mechanic, who, by his own industry, his great inventive genius and his steady application to a task which he set himself to accomplish, built up a business in this city which is known the world over, although it is not much more than in its infancy. He is of the firm of the Armington & Sims Engine Co. He is the

general manager of the company, which has recently taken the Richmond print works on Eagle street and converted them into a busy hive of industry. He is also a popular member of the Commercial Club, where he has raised his voice against the best speakers that could be brought to this city, and always in the cause of enlarging the trading facilities of the country, and giving a market elsewhere for the products of the American mills and manufacturing establishments. Such a man as he could not fail to command the entire vote of his party and the respect of the Republicans, and he might be the means of bringing to the party a healthy support from the Independents. Where opposition could come from would be a mystery, excepting that some might raise the cry that he is a gentleman." It is understood, however, that Mr. Sims will find himself unable for the present to give up any time to politics and public office.

THE UNITED ELECTRIC TRACTION CO.'S. FACTORY AT MARION, N. J.

The above company have, in their establishment at Marion, N. J., one of the largest electrical factories in the country. It covers a considerable area, and is devoted exclusively to the production of motors and of electric railway apparatus. The view which we show of it herewith is taken in the aisle of the assembling shop of the factory. The motor frames shown in the right middle ground are standard 30 h. p. motors of the traction type. It is noteworthy that this is the only shop or room in the whole factory operated directly from the engine. All the rest are driven by motor.

The United Electric Traction Co. are not only busy on general power and electric railway work, but are occupied with storage car installations. They have just sold a consignment of storage cars complete to the Citizens' Street Railway, of Indianapolis, for cash on receipt of the bill of lading. This is claimed to be the first time a sale of storage cars has ever been made, and certainly shows that the storage car "has arrived." Other installations of the same kind are being prepared.



View in Assembling Shop of the United Electric Traction Company's Factory.

NEW YORK SUBWAY WORK.

The board of electrical control met on August 22 in the mayor's office and received a report from the construction company, which shows the work of burying the wires is going on satisfactorily. The report shows that in 1889 56,035 feet of subway and 621,430 feet of ducts were laid. This year, so far, 158,181 feet of trench have been dug and 774,926 feet of ducts laid.

The Edison company made application to have subways built in a number of streets. The application was laid over. The most important subway line asked for is in Fifth avenue, from Washington Place to Fifty-ninth street.

The subway company was instructed immediately to build a subway for Third avenue through Eighty-fourth, Eighty-fifth and Eighty-sixth streets, so that wires can be extended to the East River park, which has been ordered to be lighted by electricity.

Ex-Judge Kelly, of the East River company, complained that in Twenty-third street, between Fourth avenue and Broadway to University Place, all the ducts were used up, and his company could get no accommodations. He complained that it practically shut off his company from making connections with its main lines. The subway company was ordered to provide space for the company at once.

In Twenty-third street, from Fifth to Eleventh avenue, in Forty-second street and in Seventh avenue the Brush and United States companies have lines of poles standing which are used for city lights. There are subways in these streets, and inquiry was made why the subways were not used. The companies' representatives explained that previous to the contracts awarded, a few days ago, the companies had no business in these streets, and, consequently, had not used the subways. The companies said that now that they had business in the streets the subways would be used.

The mayor said that the companies must get their overhead lines down in four weeks or he would order them cut down.

The question whether the Fire Department should have a separate duct in the subways for its wires, instead of going into

the same duct with the police wires, was only touched on in a general way. Mayor Grant had the correspondence that had passed between himself and the Fire Commissioners on the subject before him, and remarked: "I must say that the Fire Department is not facilitating the work of the board as it should."

The mayor intimated that the attitude of the Fire Board in this matter was wholly unsatisfactory to him. Henry D. Purroy is president of the Fire Board. There is a rumor that Purroy and Grant are drifting further apart than ever.

PATTISON BROTHERS.

The above electrical engineering firm of 135–137 Broadway have just finished putting to rights the lines and station of the Edison Electric Illuminating Co., of Lancaster, Pa. They have also just completed the wiring for 250 incandescent lights in John Simmons & Co.'s factory in Leonard street. They are also installing a 45-light arc plant in Sunbury, Pa., for Mr. P. B. Shaw.

THE PERKINS ELECTRIC LAMP COMPANY.

The above concern, manufacturers of the Perkins incandescent lamps and sockets, have removed their executive offices from Hartford to the factory at Manchester, Conn. Mr. M. S. Chapman is president of the company; Mr. W. G. Halm, vice-president; C. T. Welles, treasurer, and J. J. Gates, secretary and general manager.

THE EDISON-LALANDE BATTERY.

The Edison Manufacturing Co., represented by James F. Kelly, general sales agent, 19 Dey street, this city, have issued a very striking and pretty circular in colors showing the battery and its details, and giving a very neat fac simile reproduction from THE ELECTRICAL ENGINEER of July 30, of the item in regard to the extensive use made by the Western Union Co. since, and owing to, the great fire in its operating department at 195 Broadway.

NEW ENGLAND TRADE NOTES.

THE AMERICAN WALTHAM WATCH CO. has declared a semi-annual dividend of 4 per cent., payable Sept. 1.

MR. H. M. UNDERWOOD, general agent of the Interior Conduit and Insulation Company, was in Boston this week, and reports business to be something phenomenal. They are putting in new machinery at their factories all the time both for house and underground work, but have difficulty in keeping up with the demand for their goods.

THE REDDING ELECTRIC COMPANY are enjoying a great run of active business in all lines of electric supplies, and are having a brisk demand for their well known electric Watchman's Clock, the only clock which *prints* a plain record from each station. Among their most recent sales is a forty station clock for the new factory of the Woonsocket Rubber Company, making the third clock manufactured by the Redding Company which this company is using.

THE MASSACHUSETTS ELECTRICAL ENGINEERING CO. have made an undoubted success of their tested fuse wire. This wire is specially drawn for them, and carefully tested for exact carrying capacity, and a certificate accompanies each spool. They have recently had an unprecedented call for this wire, and the demand is keeping their testing department quite busy getting large quantities ready for shipment. They are filling well a long felt want in supplying a fuse wire which is absolutely reliable.

HAZLETON TRIPOD BOILER CO., of Chicago, has opened a branch for the New England States at 620 Atlantic Avenue, Boston, and Mr. William Phenix will be general agent. Mr. Phenix has had a large experience with the Hazleton tripod boilers, and he reports a rapid and growing demand for them all over the States. They are specially well adapted for electric light and power stations, taking up but little room, and requiring very little care, b sides being extremely economical and free from danger. All contractors in the East should take an early opportunity of visiting Mr. Phenix's office, where they will receive every courtesy, and be afforded an opportunity of investigating the merits of this type of boiler.

WARREN S. HILL, of Boston, is making quite a success of his patent double pole converter switch, which he designed recently for alternate current work. These switches are enclosed in small iron boxes, and should be used wherever a converter is used, as they make it perfectly safe for workmen to handle the converter or do any repairs on the secondary wires. The boxes are made thoroughly waterproof and can be fixed outside on the same pole with the converter, all that is outside the box being the handle to operate the switch. Mr. Hill has furnished several stations with a complete set, one box for each converter in use, and experience has shown that the extra expense in using them is quite insignificant compared with the extra immunity from danger in handling alternating current wires. Mr. Hill also is making large numbers of his ordinary single and double pole switches on slate bases, which are meeting with general approval everywhere.

THE ECONOMIC ELECTRIC CONSTRUCTION CO., of Boston, have now got their new factory at Brockton into proper running order, and are beginning to turn out dynamos and incandescent lamps. The factory is well adapted for the purpose, being clean, light and roomy, and they have a skillful set of men at work. In the lamp department they have at present a capacity of about 1,000 incandescent lamps a week, and they are constantly adding new machines to increase the capacity. The lamps are made of all voltages and candle-powers, and to suit any socket, and besides their own filament they use also the Siemens-Halske, for which they have the exclusive agency in the United States. The Economic Co. have perfected the type of dynamo, called the Hooper dynamo, which they will put on the market soon, and most satisfactory tests have been made with it. The dynamo is of the four-pole type, is well designed and looks extremely graceful, besides giving a very high efficiency. It is simple, easily constructed and considerably lighter than the ordinary machines of equal capacity of other manufacture.

WESTERN TRADE NOTES.

MR. G. A. EDWARD KOHLER, the Western representative of the Eddy Electric Motor Company, has sold Rand, McNally & Co. one of their large plating machines.

MR. W. H. HARDING, manager of the South Side Electric Company, is back in the city and is rapidly pushing his new station to completion. He expects to start up in a day or two.

MR. ERNEST L. CLARK, secretary of the Illinois Electric Material Co., has been in Quincy, Ill., for the past week, on business connected with the electric street railway there.

THE POND ENGINEERING CO. are installing the large steam power plant for the Calumet Electric Railway Company at South Chicago.

MR. FOREE BAIN has just completed some highly satisfactory tests of his new 100 horse power generator. This machine only absorbs ¾ of 1 per cent. of the output for the magnetization of the field, which is a highly desirable feature.

MR. POND, of the Pond Engineering Company, has been in town for the past few days. He has been kept busy with Mr. Albert Blanchard, his Chicago representative, in looking after the large business which has been worked up here and in the vicinity by that able gentleman, who is well known among the fraternity as a hustler.

MR. W. S. ARMOUR, the Chicago agent of the Detroit Motor Company, 320 The Rookery, has just placed a 7½ horse-power motor on the Edison circuit. This motor will operate the printing establishment of R. R. McCabe & Company, 334 Dearborn street, in the new Caxton building.

THE WESTERN POWER CONSTRUCTION CO. are doing lots of business, and the factory at Auburn, where the well-known McIntosh-Seymour engines which they handle are manufactured, is pushed to the utmost to fill their numerous orders. Mr. Waldo P. Adams, the general manager of the Western Power Construction Co., is in town again, back from a trip to the East in which he was highly successful in securing business.

THE SPERRY ELECTRIC CO. are receiving inquiries from all over the country regarding their new triple carbon lamp, which is creating quite a sensation. Their lightning arresters have shown some remarkable proofs of their reliability and efficiency, one of them in taking care of no less than 15 strokes in two hours during a recent storm without a cent of damage. They are now putting an improved form of this arrester on the market.

THE ILLINOIS ELECTRIC MATERIAL CO. are meeting with great success with their new woven insulated line wire. Mr. "Canvas-Jacket" Hoefer, the general manager of the company, reports the demand for this wire as unprecedented. He is now known by the above appropriate title amongst his electrical friends in town, who keep continually asking him "What is Canvas-Jacket?" Mr. H. S. Winston, the president of the company, has returned from the convention at Cape May, well pleased with the results of his Eastern trip.

THE PUMPELLY STORAGE BATTERY AND ELECTRIC MOTOR CO., 129 La Salle street, Chicago, have shipped 37 cells of battery to J. H. Munson & Company, at Evanston, Ill., where they will be employed by Mr. Munson, who till recently has been the electrical expert of the university there, for lighting the incandescent lamps which will decorate his four-horse wagon in which he will attend the business men's picnic there. In this he has introduced some striking novelties in lighting effects obtained by the revolution of the wheels cutting lights in and out. He will also use the current to operate some small motors.

THE

ELECTRICAL ENGINEER.

[INCORPORATED.]

PUBLISHED EVERY WEDNESDAY AT

150 Broadway, New York City.

GEO. M. PHELPS, President. F. R. COLVIN, Treas and Business Manager.

EDITORIAL ANNOUNCEMENTS

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, SEPTEMBER 10, 1890. No. 123

This, the greatest by far of all the marvels of the electric telegraph.—Sir W. Thomson.

NEW YORK'S TELEPHONE SERVICE.

CLOSE to the telephone now in use in the printing office of THE ELECTRICAL ENGINEER is nailed a dingy old yellow card, in which the instructions given to the subscriber read: "To Call Central Office: Press the button three times, take the telephone from the hook and place to your ear, and listen for a response. * * * When through talking, hang up the telephone, and then press the button three times." Such was the crude and archaic method of signaling "central" a few years ago, and the distance traveled, as well as the enormous improvements made, since that old card was put up, can only be realized by reading the excellent article contributed to our pages this week by Mr. Herbert Laws Webb on the telephone service of New York to-day. It is safe to say that able, intelligent and progressive as were the men who directed affairs in the early telephonic days in this city, they had not the remotest idea of the shape that the service and apparatus would take under the pressure of new conditions, and thanks to the efforts of inventive genius or trained experience.

It has been the fashion, and a sorry one, to find fault with the telephonic management in our leading cities as at once parsimonious and incompetent; but no one can read Mr. Webb's account of what has been done, and is still to be done, without feeling how great is the thought and care that is directed to the perfection of the work. The problems that come up for solution are among the most complex and abstruse that offer themselves to the modern electrical engineer, and while no one believes that the goal has been reached, it would show little appreciation of zeal, skill and energy not to praise such achievements as this article brings before us. Not even a hundred articles of equal length could tell of all the labor and experiment, to say nothing of the capital required to attain these definite, practical results that constitute the basis of the methods employed to-day.

An instance of the manner in which the telephone manager and engineer have had to grapple with new conditions is presented in Mr. Webb's description of the underground system. A very few years ago the wires were all overhead, and we have in our possession an old cartoon from one of the comic papers in which the telephone service is represented by a big spider at the centre of a huge cobweb of wires. To-day, in New York, as Mr. Webb shows, there are in operation from the different exchanges nearly 300 separate underground cables, each containing 50 twisted pairs of conductors, aggregating 145 miles of cables or 14,553 miles of wire. The next cartoon will evidently have to depict a hydra with heads or tails out of a hundred cavernous lairs. These cables represent, of course, an immense investment, and their maintenance and testing has become one of the most important branches of the work.

Altogether, we think the Metropolitan Telephone Co. has evinced in a praiseworthy manner a desire to meet all the needs of the hour; and the articles appearing also in this issue as to work in Philadelphia and Hartford indicate the same spirit of progress and improvement. It is in this way that preparation is rightly made for the future, and the business held, not simply because the service is the only one, but because it is the best.

DANCING TO MUSIC FROM AFAR OFF.

ON Thursday night last an interesting and really notable musical and vocal entertainment was given from New York to a very large audience assembled at the Grand Union Hotel, Saratoga.

As our readers will conjecture, the audience, which numbered at times no less that 800 people, was brought *en rapport* with the performers by means of a "Long Distance" telephone circuit running a distance of 180 miles from 18 Cortlandt street, New York, to Saratoga. From Cortlandt street a circuit had been run to the Madison Square Garden and the concert being given by the Strauss Orchestra was taken in alternation with the other numbers of the programme which comprised selections by the Long Distance orchestra, flute and cornet solos, a whistling song and glees by members of the technical staff, one of whom also recited Tennyson's "Charge of the Light Brigade." The orchestral music was listened to at Saratoga by means of sets of hand telephones, and every note was heard distinctly, even to the applause of the audience gathered at Madison Square. Some of the songs and solos and the recitation were heard all over the room at Saratoga by means of a single loud speaking receiver provided with a large funnel-shaped resonator to magnify the sound. Great delight was expressed by the audience at Saratoga with the evening's entertainment, and the exhibition was considered one of the best and most successful that has yet been given over the Long Distance Company's system.

A very novel and striking use was made of this tele-

phonic concert by Mr. A. S. Hibbard, who happened to be entertaining a number of his friends at his residence in Morristown, N. J. the same evening. Mr. Hibbard's private telephone line was connected at Cortlandt street with the circuit running to Madison Square Garden and the strains of the famous orchestra were heard so plainly in the house at Morristown that dancing was carried on with perfect ease and comfort by the guests there assembled.

If some one had told Herr Strauss that his orchestra was playing for dancers who were enjoying themselves at Morristown, some twenty or thirty miles distant, the information would probably have been received with sheer incredulity, yet such was actually the case. Two Strauss waltzes were enjoyed by Mr. Hibbard's guests and afterwards the orchestra at Cortlandt street was switched in and dancing was continued by the music of the less ambitious band of performers.

We believe this is the first instance recorded of the transmission of music by telephone with sufficient volume and clearness for dancing to be indulged in by the listeners.

MULTIPLE SWITCH-BOARDS.

Though to an outsider who rarely enters an exchange telephony may appear to have become stationary so far as improvements in the art are concerned, much in reality has been accomplished during the last few years, and the results of this work are already beginning to make themselves felt. A single improvement alone, that of the multiple switch-board, over the single boards with their intermediate connections, has done much to simplify the work within the exchange, but the enormous increase in the number of subscribers connected to one exchange has made even the multiple board unwieldy to some extent in our largest exchanges. As a result, steps are already being taken to increase the capacity of the central office operator by differentiating subscribers into groups and giving the calling subscriber the power to call up either group by a simple manipulation. This has been very well carried out in the multiple switch-board designed by Mr. M. G. Kellogg and described on another page. The saving in the cost of the office equipment brought about by means of this system will at once be obvious, and the means by which this has been carried out are exceedingly simple and ingenious. The employment of the telephone magneto to send currents of either polarity to line is a decidedly novel application and might possibly be used in certain forms of telegraph work.

LOCKWOOD'S TELEPHONE SYSTEM.

The great success which has attended the employment of closed circuit transformers in electric lighting by the alternating current would naturally suggest the employment of this type of transformer or induction coil in telephony, and indeed such a transformer was proposed some time ago, but its employment directly, in place of the open circuit transformer, was accompanied by difficulties, principal among which was the fact that the nature of the current in the primary circuit was not of an alternating character, but was one involving simply a change in strength without a change of polarity. The reasons which prevented the direct employment of the closed circuit transformer for telephonic work are, therefore, practically the same as those which have made it unsuitable for employment as an induction coil where it is intended to produce a disruptive or spark discharge. In seeking, nevertheless, to employ the closed circuit type of transformer in a telephonic circuit, and thus to throw effective alternating currents upon the line, Mr. T. D. Lockwood has hit upon the ingenious idea of combining the open circuit with the closed in the manner described elsewhere in this issue. The method is one which might possibly be employed in other branches to obtain a true alternating current from a pulsating continuous current.

Tesla Alternating Current Motors.

In a recent issue we described at length some new forms of alternating current motors designed by Mr. Nikola Tesla, and involving some novel methods for producing motion in contiguous circuits acted upon by alternating currents. In a short review of this article appearing in our excellent contemporary, *Industries*, a writer accuses Mr. Tesla of holding to the old fallacy of the screening action of the iron to explain the action of his machine. A careful study of our original article makes it apparent, however, that our contemporary has misunderstood the character of the machines described. It would take us too long to point out the error into which our contemporary has fallen, and to state in exact terms just what is accomplished by the construction adopted in Mr. Tesla's machine, but in answer to the closing remark of our contemporary, it is incumbent upon us to state that machines constructed on Mr. Tesla's principles are in actual commercial operation at the present time with no small measure of success.

The Unit "Henry."

Prof. F. B. Crocker has an interesting letter in this issue, in which, while expressing his pleasure at the support given by Dr. Fleming to the new units, he differs from that authority as to the advisability of abbreviating "henry" into "hen." In our remarks on Dr. Fleming's recent letter in these pages, we called attention to his suggestions as to "frank" and "gilb." On the whole, we think that while "frank" and "gilb" may pass muster, "hen" would hardly do so. There is an invitation to ribaldry and irreverent mirth about it, and no one would be surprised to hear a playful junior engineer, who meant to speak of "microhens" referring to them as so many "spring chickens." The Institute will have this matter of new units up during the month, when Prof. Crocker will deliver an address on the subject, and the discussion promises to be one of great interest.

Open Circuit Transformers.

Notwithstanding the almost universal employment of closed circuit transformers in alternating current work, Mr. James Swinburne has taken up and championed the cause of the open circuit type. While Mr. Swinburne admits that the efficiency of the closed circuit type of transformer is higher at full load than that of the open circuit, he claims for the latter a higher average all-day efficiency, and hence advocates its use. The details of construction given on another page will prove of interest to the reader, the omission of all iron or metal in the casing of the transformer being an interesting point.

ELECTRICAL ENGINEERS.

ALEXANDER GRAHAM BELL.

THE history of the practical development of the telephone and the telephonic art has been so often retold during the past 12 years in the litigations that have attended the establishment of commercial telephony, that its main facts are as well known as those connected with the invention of the telegraph. The literature of telephonic litigation constitutes, in fact, a library of astounding proportions, and it would seem as though there were little left to be said in that department of the subject. But, strangely enough, in spite of all this controversy of great lawyers and experts and the struggle for supremacy of embattled millions of capital, the career of Alexander Graham Bell, the inventor of the speaking telephone, has rarely been made a theme for gossip in the public prints. He has never cared to gratify natural curiosity, but, on the contrary, has generally held the paragrapher of the society journal and the interviewer of the daily paper at arm's length. This reserve is characteristic of the man, but we do not think that we disregard it in now giving his portrait to our readers with a few of the leading events of his life.

Alexander Graham Bell

Alexander Graham Bell was born at Edinburgh, Scotland, on March 3, 1847, of good old stock. His father and grandfather were both teachers of languages, etc., and his father, Alexander Melville Bell, who is still alive, has long enjoyed a reputation in the field of philology and linguistics, being the deviser of ingenious systems of "world speech" and "visible speech." He intended that his son should follow his profession and early gave him instruction in the anatomy of the vocal organs, their various functions and the different subjects belonging generally to the science of vocal physiology. When quite a child, A. G. Bell was told by his father of an automaton speaking machine he had seen, and the boy was so interested that he determined to attempt the construction of such an apparatus himself. In a word, he then and there invented a speaking machine, built it and made it articulate one or two simple words. While at Elgin, in Scotland, he found out for himself, also, that the elements of speech were compound in their nature, and became interested in the important work done by Helmholtz, relating to the quality of vocal sounds. In 1865, the family removed from Scotland to London; and about 1866, at Bath, in England, he conceived the idea of following up Helmholtz's synthetical experiments in the reproduction of sound, by attempting to transmit speech electrically. Between the years 1867 and 1870, he made numerous electrical inventions based on the Helmholtz vowel apparatus, and, before he left England, had resolved to pursue one of these inventions, that of harmonic or multiple telegraphy, to a practical outcome. The idea of actual speech transmission was running in his mind all this time, like an undercurrent of thought that he could hardly formulate in definite expression; but it gradually took clearer shape, and Mr. Bell has stated on the witness stand that to friends in England, before 1870, he avowed his belief that we should "one day speak by telegraph." He did not himself imagine for a moment that that great achievement was to be his, but if ever a man were fitted to produce such an invention, by heredity, education, surroundings and temperament it was surely he.

In August, 1870, the Bell family emigrated from England, to Brantford, Canada, and in April, 1871, A. G. Bell went thence to Boston, on the invitation of the Boston School Board, to carry on a series of experiments with his father's system of "Visible Speech," or physiological symbols for the deaf. He remained permanently in the neighborhood of Boston, from October 1, 1872, until his removal to Washington, in 1881. From the very moment of his arrival in Canada, in 1870, up to the beginning of 1874, his mind was full of the scheme for the multiple transmission of telegraphic messages by means of musical tones, and he had other telegraphic inventions also in hand; but the old idea of speech transmission was persistent in claiming his attention, and gradually his thoughts and energies were narrowed down to this one field of investigation. He has himself narrated more than once the manner in which he proceeded, stage by stage, from his experiments with phonautographic apparatus, human ear drums and apparatus for obtaining undulatory currents, up to the period when he and his assistant, Mr. T. A. Watson, were able to talk to each other telephonically over a short line in the Boston University, and when by rapid strides the crude apparatus was improved and brought up to a fair degree of efficiency. The first tests with the telephone as a speech transmitter were watched with great interest by many scientific men to whom Bell communicated his results freely and from whom he received many valuable suggestions; but the press and public were sceptical in regard to the reports that began to circulate. Bell's first public lecture on the telephone was delivered before the Society of Arts, Boston, May 25, 1876; but the first time that speech was transmitted over a real line was August, 1876, at Brantford. He hastened to patent his invention, and the same year exhibited it at the Philadelphia Centennial Exposition, where a memorable display of its speaking powers was made on Sunday, June 25, 1876, before Sir William Thomson, the Emperor of Brazil, Prof. Sterry Hunt, Dr. Draper, Dr. Koenig and others.

The vicissitudes of the Bell telephone from that time are a familiar and hackneyed story, both as to its commercial development and the various infringement suits brought successfully by the American Bell Telephone Co. against

a number of persons, the most prominent of whom were Meucci, Dolbear, Drawbaugh, Clay and Cushman. The litigation between the Western Union Telegraph Company and the Bell Telephone companies resulted in a compromise, by which the priority of Bell was recognized, and the former company granted the latter an exclusive license under its Page, Edison, Phelps, Gray and other patents held to be controlling in various respects. The long warfare in the courts may be said to have reached its conclusion, when the Supreme Court of the United States sustained Bell, for nothing is ever expected to come of the absurd suit brought against Bell, in the name of the Government, for fraud in obtaining his patent.

In the fall of 1877 Prof. Bell married Mabel, the daughter of Hon. Mr. Gardiner G. Hubbard, to whom he had been indebted for financial aid in developing his inventions; and who, with others, has since reaped a rich reward for courage and foresight. It was through his position as instructor to Miss Hubbard, a deaf mute, that Prof. Bell became acquainted with Mr. Hubbard.

From first to last Prof. Bell has taken out twenty-one United States patents, as sole or joint inventor, the most important being, of course, the one on which is based the speaking telephone of to-day. The photophone, however, upon which he has worked, stands high also as a scientific achievement. Being decreed the French Volta prize, he devoted the money to the establishment, in Washington, of the Volta Laboratory, with a view to original investigation in the transmission and reproduction of articulate sounds; and the Association, as it was called, formed at that place included Mr. Chichester A. Bell and Mr. Sumner Tainter. Several inventions have been the result of the labors of the Association, principally the jet telephone and the graphophone. Prof. Bell has also, to some extent, given attention to devising improved methods of electrical communication between vessels at sea. Of late years, however, Prof. Bell has mainly devoted himself to his original pursuit, namely the study of the deaf and dumb, in connection with his father's visible speech; and he has given much thought, with no small measure of success, to the amelioration of the condition of such unfortunates.

Immediately after the invention of the telephone and its going into commercial use, Prof. Bell was called upon for papers and lectures, and for a time he yielded gracefully to the demand. Among the most noteworthy of his productions are: "Researches in Electric Telephony," a paper read before the English Society of Telegraph Engineers, London, October 31, 1877; "The Production and Reproduction of Sound by Light," a paper read before the American Association for the Advancement of Science, August 27, 1880, relating to discoveries made by himself and Mr. Sumner Tainter in the art of "Radiophony"; and "The Production of Sound by Radiant Energy," a paper read before the National Academy of Sciences, April 21, 1881, relating to further investigations of the same nature.

ELECTRIC RAILWAY TESTS IN BOSTON.

The West End Street Railway Company are making an extensive trial this week of different forms of truck, for the purpose of satisfying themselves which is the most economical in consumption of electrical energy in all conditions. The Ffinsk truck, the Tripp truck, and the Robinson Radial truck, are among those being tried, and they are all loaded down with sacks of meal weighing an equivalent of 100 passengers at 140 pounds each. The cars are being run back and forth between Grove Hall and Forrest Hills, and will run continuously all day, ampere readings, volt readings, and Edison metre readings being carefully taken, as well as a careful record of the speed by a tachometer. There are now in Boston nearly 300 electric cars in daily service, and the load is getting to be fairly constant, the ammeters in the power station showing but little fluctuation. The heavy granite foundation work at the central power station is about completed and the brick work is in rapid progress, and preparations are being made for work on the girder roof. The new Cambridge power-house is also making rapid progress.

THE NEW YORK TELEPHONE SERVICE.

BY HERBERT LAWS WEBB.

There are comparatively few people who appreciate the vastness of the telephone system in a great city like New York, and still fewer that have the opportunity of seeing from the inside the enormous difficulties to be overcome by telephone engineers in order that the service may reach that point of efficiency which they are always striving for and which impatient subscribers declare—in language more forcible than polite—to be unattainable. There are carping critics, generally newspaper scribes in want of a better subject upon which to expend their power of invective, or individuals belonging to that class of present day offenders against our peace and happiness who *will* write letters to their favorite daily organs on matters about which they are profoundly ignorant, who maintain from time to time that the telephone companies persist in rubbing along with antiquated apparatus, rusty and badly constructed lines and a general state of cheap disorganization, so that, secure from competition as they are, they may continue to extract from the poor down-trodden subscriber, the maximum *quid* in the way of rates in return for the minimum *quo* in the shape of service. That such a state of affairs does not exist, and, in the more important companies, never has existed, goes without saying, but even many of our readers who keep themselves well informed on telephone matters will learn with surprise of the high pitch to which the methods, and what may be termed the technical policy, of the Metropolitan Telephone and Telegraph Company have been brought, and how wide a difference exists between the actual state of matters telephonic in New York, and the lugubrious descriptions of them doled out to readers of the daily press. During the past few years the enormous plant of the Metropolitan Company has undergone, and, in fact, is still undergoing, a gradual and complete reorganization, and it is not too much to say that in the system of equipment for the new buildings now elaborated, the very acme of perfection in modern telephone working has been reached.

Beginning with the Cortlandt street exchange, situated at No. 18 Cortlandt street, familiarly known as "Telephone Headquarters," we find a Western Electric multiple switch-board with capacity for 6,000 metallic circuit subscribers; this board occupies the entire floor of the eighth story of the building, and has assimilated the subscribers formerly connected to the old exchanges at John, Pearl, Nassau and New streets. The engraving, Fig. 1, shows one side of this board. Quite recently another of the old down-town exchanges, that at Murray street, has been abandoned and its subscribers transferred to Cortlandt street and to the present exchange at Spring street and Broadway. This exchange, again, will shortly be installed, with an entirely new plant, in a model telephone building erected by the Metropolitan Company at the corner of Spring and Wooster streets.

The Cortlandt street board, which is the largest multiple switch-board in the world, has been in operation for about two years, and is now operating more than 3,800 subscribers, many of them equipped with metallic circuit lines. The average daily number of connections between subscribers made on this board is 48,236 and the average for the whole city is 103,621, about 93 per cent. of these connections being made between the hours of 8 A. M. and 6 P. M. At present there are 128 operators at Cortlandt street, each one of whom attends to between four and five hundred subscribers' calls per day of ten hours. The switch-board has given excellent service since first put into use and a few minor changes shortly to be made in its equipment will still further increase its efficiency.

The most interesting part of the Cortlandt street building for many readers of The Electrical Engineer is where comparatively few visitors penetrate; below the ground floor is a department known as the "underground room," where the cables which find a deviating and tortuous path through

New York's much abused subways terminate and make connection with the switchboard eight floors above. The room in its present state is not calculated to impress the technical man very favorably. As originally planned, the cable terminals were to be connected to the switchboard through a distributing board which lines the walls of the operating room at the rear of the switchboard. This distributing board consists of a series of vertical wooden racks placed at convenient distances apart to facilitate the handling of wires; above the racks are arranged the lightning arresters and resistance coils. The underground cables are extended from the cellar by flexible rubber covered cables running in ducts the height of the building and connected to one side of the lightning arresters and resistance coils. The distribution is then effected by running wires through the racks from the lightning arresters to the part of the switchboard required, the connection to the wiring of the board itself being reached by running the wires through troughs under the floor and up at the back of the board.

The underground system, however, has grown at such an extraordinarily rapid rate, that this method of effecting the "cross-connecting," a very important part of the daily work of a large telephone exchange, has outgrown its usefulness, so much so, that much of the cross connecting work necessitated by cutting new underground cables into service, changes in subscribers' addresses, etc., has had to be done in the underground room.

The problem of reducing cross-connecting to a systematic process devoid of all risk of confusion or literal "cross-connections" involving trouble and annoyance to all parties concerned, has lately been attacked in earnest, and the investigations conducted by telephone engineers has led to the invention and development of the Hibbard distributing board, which is illustrated in perspective view in the accompanying engraving, Fig. 2, which represents the one to be placed in the underground room at the Cortlandt street exchange. Mr. Hibbard has solved in a very simple manner the difficulties of "cross-connecting," and his distributing board is already in operation in several of the principal exchanges in the country, such as, for instance, those at Philadelphia, Boston, Baltimore, Albany, etc.

The engraving gives a general idea of the board. In telephone work the word "board" has got to be quite a conventional term, and in this case it stands for a framework built up of iron gas pipe and rods, of long and narrow dimensions, the vertical parts of the frame serving for supporting the hard rubber bases to which the connecting devices are attached, and the cross bars forming supports for the cross connecting wires which run through the frame-work from side to side. It is plain that if at each side of the frame-work we have a number of hard rubber strips provided with small metal plates to which wires are permanently connected, it will be a perfectly simple matter to connect any two wires terminating at one side of the board to any two terminating at the other by merely running a

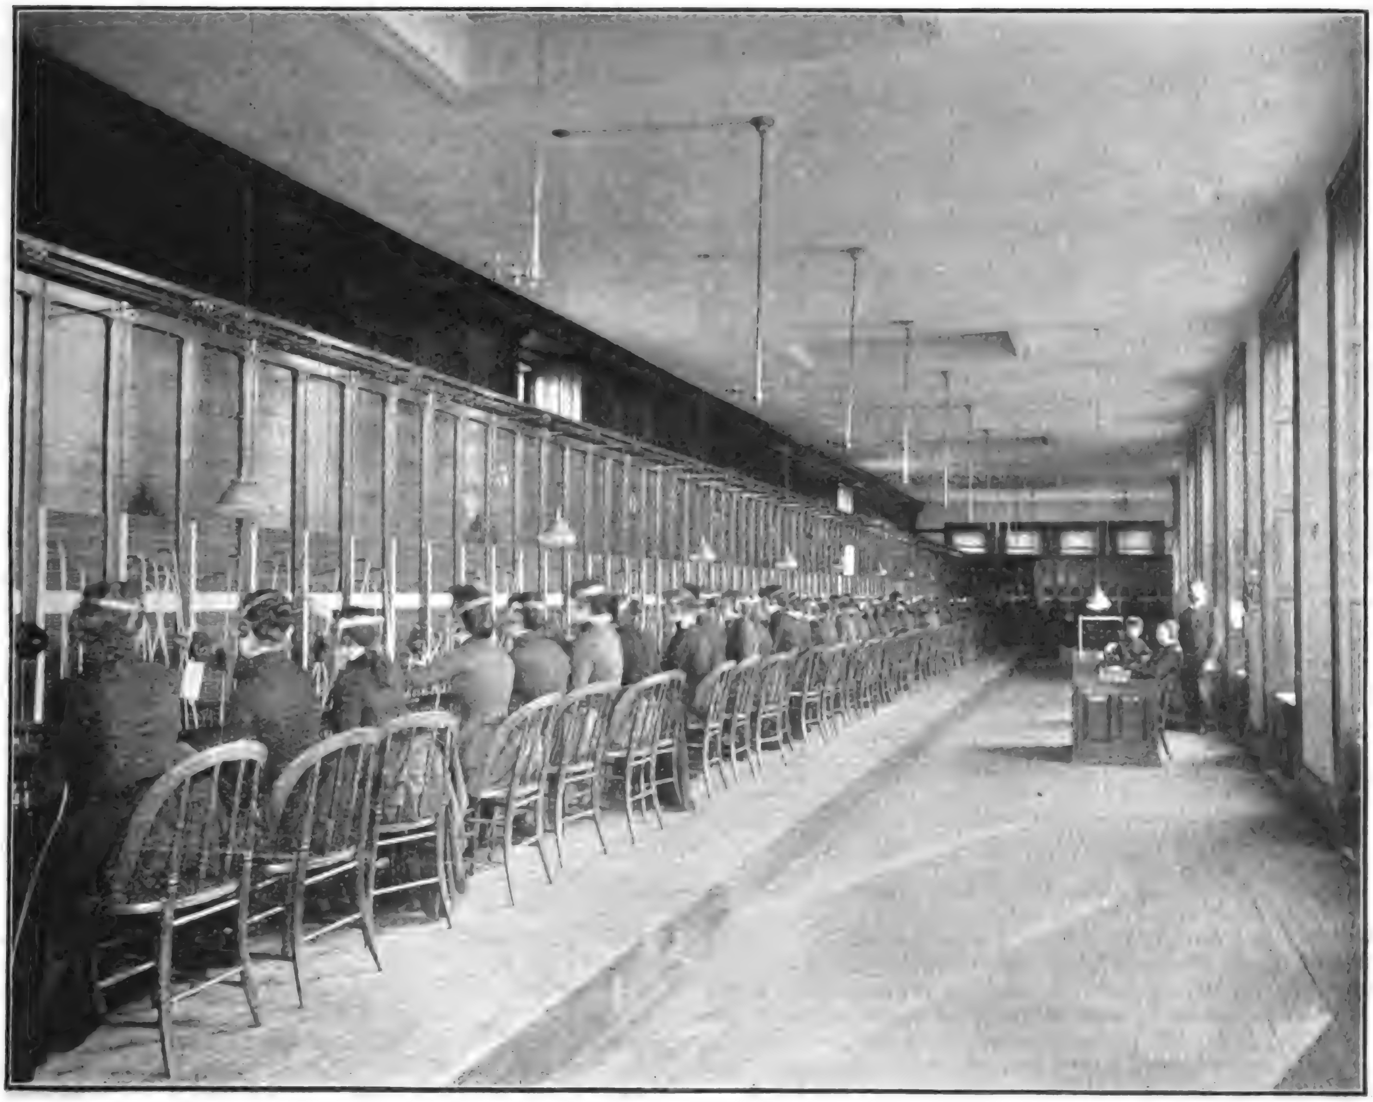

FIG. 1.—ONE SIDE OF THE NEW MULTIPLE SWITCHBOARD AT THE CORTLANDT STREET EXCHANGE, NEW YORK.

pair of wires through the racks in the middle of the frame-work.

The arrangement of the underground room at Cortlandt street when the new distributing board is in place will be as follows: Above the iron cable heads which form the terminals of the underground cables will be placed hard rubber strips provided with the proper number of Hibbard lightning arresters for each cable, and the cables will all be wired permanently to these arresters, all connections being soldered. From the arresters to the connection strips on the distributing board short cables will be run, thus extending the underground cables direct to one side of the distributing board, the only intervening piece of apparatus being the lightning arresters; as a break can be made in the line at this point by the removal of the fusible coil it is an easy matter to test any line in either direction when hunting for "trouble" on a subscriber's wire. In the same way cables will be run from the switchboard to the strips at the other side of the distributing board; these cables will be soldered direct to the switchboard terminals in the operating room, and also to the metal ears on the hard rubber strips of the distributing board, the wires belonging to the different drops being arranged in proper order, drop number one being the first connection on the first strip.

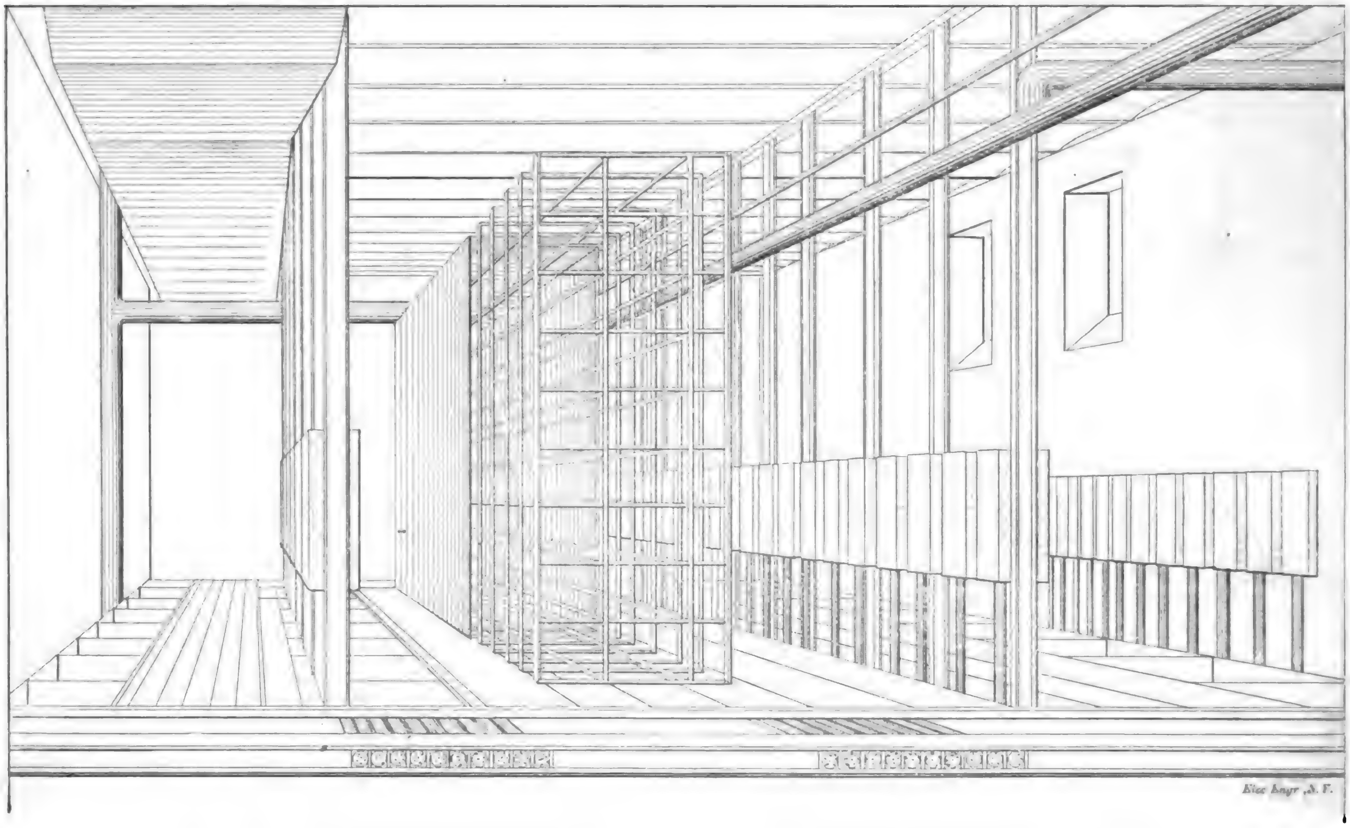

FIG. 2.—THE HIBBARD DISTRIBUTING BOARD AT THE CORTLANDT STREET EXCHANGE, NEW YORK.

This arrangement practically means the transfer of the switchboard terminals to the terminals on one side of the distributing board. We now have the terminals of the underground cables and those of the switchboard brought face to face, or rather back to back, separated merely by the iron framework, and in order to connect any desired pair of wires in any underground cable to a drop in any part of the switchboard, the only operation necessary is to run a pair of wires through the rack, making the requisite connections at each end. This will be the only cross connection between a subscriber's line and the drop required at any part of the exchange, and it will easily be recognized that this method of doing the work simplifies matters to a very great extent and renders it possible to make any number of changes between lines and their drops with the minimum expenditure of time and labor and the maximum amount of certainty.

The board designed for Cortlandt street will be 38ft. long, 7ft. high and 3ft. 1in. wide, and will have thirteen separate planes on which the cross-connecting wires will be run. All the cross-connecting wires will be rubber covered and twisted in pairs. The board has capacity for 154 underground cables, or, say, 7,700 pairs of wires. The cross-connecting wires will never be run diagonally through the framework, but when a connection has to be made between a point high up on one side of the board and another low down on the other the connecting wire will be run horizontally on the plane coinciding with its starting point and then up or down when opposite its destination in a vertical division of the framework at the rear of the board; in this way the openings at the front of the board will never be obstructed by the cross-connecting wires, the maximum number of which in any one plane will be about 600 pairs.

The work of putting in the distributing board is to be commenced very shortly, and from the description already given a faint idea may be formed of the magnitude of the task, involving the entire reorganization of all the connections between the underground cables and the switchboard and the making of some tens of thousands of new connections.

The underground plant of the Metropolitan Company has had a marvellously rapid growth since the inception of the underground wire regulations in New York. At present there are in actual operation from the different exchanges nearly 300 separate underground cables, each containing 50 twisted pairs of conductors, aggregating 145.5 miles of cable or 14,553 miles of wire. The Cortlandt street exchange, of course, has the greatest number of cables, as no less than 140 of the 300 terminate at this office. The cables vary greatly in length, as some are only a few hundred feet long running to buildings in or near Cortlandt street, where they terminate on roofs and are extended to subscribers' offices by overhead wires. There

are many cables over a mile in length, the longest being one of two terminating on a pole at Fifty-ninth street and Tenth avenue, which measures 29,069 feet, or nearly six miles.

The cables used are all made to conform to a set of specifications exacting certain electrical and mechanical requirements, and each cable is tested for insulation and conductor resistance and inductive capacity before it is accepted by the company and put into service. Full records are kept of all these tests so that the life of every cable can be watched from the time it is first laid down. At Cortlandt street a testing room has been fitted up containing a complete set of fine testing instruments, leads being run to the underground room where connection is made with the cable heads.

At Spring street, Eighteenth street, Thirty-eighth street and Seventy-ninth street nearly all the subscribers' lines enter the exchanges through underground cables, and the rapidity with which the underground work has been pushed has necessitated an equally rapid and radical change in the equipment of the company's central offices. The Cortlandt Street Exchange is a modern telephone building, but changes there, as we have seen, have become necessary long before the building has lost its modern air. With the other exchanges the company has adopted the very sweeping policy of entirely abandoning the old plant and removing the subscribers' wires to entirely new buildings erected by the company and equipped throughout as model telephone buildings, according to the most approved principles of telephone engineering, as that branch of the science is understood to-day.

One of these buildings has just been inaugurated at West 38th street, the lines formerly running to the old exchange, at 39th street and Sixth avenue, having all been transferred to the new office less than two weeks ago. A similar building has been erected at the corner of Spring and Wooster streets, and the transfer of the old Spring street exchange to the new will be made by the beginning of next year. Another telephone building is to be located on Franklin street, and still another at Broad street. These four new offices will have an aggregate capacity for operating 14,400 metallic circuit lines. Uptown, a new office will shortly be established at 79th street and Third avenue, and the Harlem exchange is being rehabilitated in order to arrange the apparatus for metallic circuit working; to place the Harlem exchange in connection with the underground system a subway is now being built in that direction, the route of which for a considerable distance passes through solid rock which has to be blasted out in order to provide a passage for the subway.

The equipment of the new telephone buildings will not differ materially from that of the Cortlandt street office, with the exception that all the vital parts of the offie will be on the same floor. Instead of terminating the underground cables in the cellar they will be run up a shaft to the top floor, where a "terminal room" will be provided for their reception. The Hibbard distributing board will be located in this room and the cross connecting will be done as already described. In the terminal room there will also be a chief inspector's desk provided with spring-jacks and connections, by means of which the chief inspector can plug on to any faulty line a set of testing instruments consisting of Wheatstone bridge, galvanometer, relay, etc., and so determine the nature and approximate locality of the trouble. This chief inspector will have charge of all the "trouble men" attached to his exchange, and will keep full records of all incidents connected with the maintenance of the lines. In all exchanges, current for ringing up subscribers is supplied by small power generators run by electric motors; these are located in a separate department called the power room, which also contains a large battery of gravity cells to be used in connection with a pole changer in case of the motors or power generators being disabled at any time.

Needless to say that all these exchanges are equipped throughout on a basis of metallic circuit working; before very long, as indicated in this article, New York will be provided with a group of telephone exchanges embodying every appliance which the best telephone engineering talent in the country has been able to bring to bear upon the complex and many-sided problem of maintaining an efficient service of telephonic communication in such a city as New York.

If any newspaper scribe, before he lightly sits himself down to indite a diatribe against the niggardly economy of the telephone companies and their systematic suppression of improvements in methods and apparatus, would pay a visit to one of these exchanges he would find both methods and apparatus of a far higher standard than in many other technical establishments. Then let him figure out the cost of an eight-story telephone building, of a multiple switch board for 3,600 subscribers, of the distributing board, motors, generators and batteries, of the miles and miles of wire within the building and the miles of underground cable without, let him ponder over the cost of maintenance and the salaries of a staff which would fill a good-sized theatre, and if the calculation leaves him still with power to think he will think twice before informing the public that the telephone companies spend no money and merely plot day and night to achieve the difficult operation of catching whales with sprats.

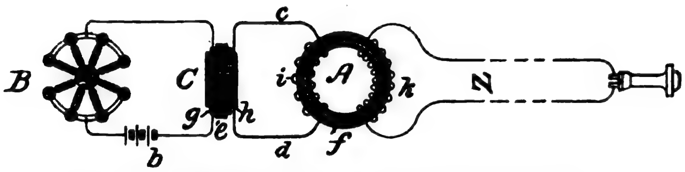

FIG. 1.—LOCKWOOD'S NEW SYSTEM OF TELEPHONY.

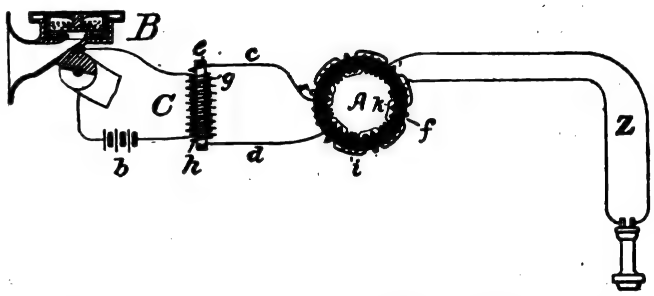

FIG. 2.—LOCKWOOD'S NEW SYSTEM OF TELEPHONY.

LOCKWOOD'S NEW SYSTEM OF TELEPHONY.

It has long been customary to employ induction-coils in connection with telephonic transmitters for the purpose of transforming the low-potential current of the energizing-battery into one of higher potential and better fitted to traverse the long line-conductor and to overcome its resistance with little loss of energy, as well as for the analogous purpose of very materially increasing the margin of variation producible by the operation of the transmitter. Up to the present time the induction coils employed for telephonic purposes have been almost universally made with cylindrical cores; that is, with open magnetic circuits. In contemplating the high efficiency attending the employment of induction coils or transformers of the closed circuit type used in electric lighting, welding, etc., Mr. T. D. Lockwood, the well-known electrician of Boston, has sought to employ such a form in telephony. But the employment of closed circuit induction coils in telephony involves certain considerations which do not appear at first sight. It is, of course, comparatively easy to operate electric light transformers by means of reversals of the primary

current, because, since the secondary currents to be evolved need have no special form, character, or quality, these reversals may readily be produced by using an alternating dynamo as a source and by sending its currents unrectified through the primary helix. But no such procedure is possible in telephony, for the voice-currents developed in the secondary circuit of the induction-coil, which are to traverse the line and reproduce speech at the distant station, must, so to speak, be an electrical copy of the variations of the sound-waves initiating them, and also of the sound-waves they are to reproduce. Up to the present time, however, it has not been found practicable to produce reversals in the primary circuit of transmitting telephone induction-coils, and in all such instruments which have gone into use the change which the operation of the transmitter effects in the primary circuit is not a reversal of current, and hence cannot result in a reversal of magnetism with its inherently-consequent zero moment. It is not even a succession of absolute cessations and emissions of current, as in the make and break of the Ruhmkorff induction-coils. The change which is effected by such operation is the variation of current strength, tending to produce a variation of magnetic intensity in the core, which, if produced, results in corresponding magneto-electric currents in the secondary helix and line; but the magnetism of an iron ring core once magnetized does not greatly vary when simple changes only are made in the strength of the magnetizing-current. Thus, while it tends to advantage to employ induction-coils having closed magnetic-circuit cores, such a procedure demands also a practical method of producing reversals in the primary circuit of the induction-coil, and it is to accomplish the latter object that Mr. Lockwood has designed the system we are about to describe.

The method employed is illustrated diagrammatically in Fig. 1. Here B is a multiple-contact microphone which is placed in the circuit of a battery, *b*, in which also is serially included the primary conductor, *g*, of the induction-coil, C. This circuit may be termed the "local circuit." The secondary conductor, *h*, of this coil has the same number of convolutions and is of the same size wire, and both are, as usual, wound upon a cylindrical core, *e*, of iron wires.

The induction-coil, A, has a continuous core, *f*, of soft iron, and constituting a closed magnetic circuit. This has a primary conductor, *i*, the same size and length as that employed in the two helices of the first coil, which is joined up in circuit with the secondary conductor, *h*, of induction-coil, C, and the closed circuit so constituted may be termed the "intermediate circuit." Thus alternating currents generated in conductor, *h*, inductively by changes of current in conductor, *g*, will be of like character with such changes, and will of necessity circulate in and through the primary conductor, *i*, of induction-coil, A. The resistance of the conductors, *g* and *h* and *i*, is low, being but a fraction of an ohm.

The secondary conductor, *k*, of coil A, is of fine wire, for the purpose of securing a great many convolutions, it being required not only to transfer electrical energy from the reversals circulating in *i* to the secondary conductor, *k*, but to raise the potential. The secondary, *k*, of the induction-coil, A, is connected with the wires of the main telephone-circuit, Z, leading to the distant station and telephone-receiver. The construction of the apparatus employed in actual practice by Mr. Lockwood is shown in Fig. 2. The position of the second induction-coil, A, and its connections are the same as those shown in Fig. 1, the only difference being in the method of winding. Here, it will be noted, the primary coil, I, is wound in alternate sections, spaces being left between each for similar sections of the secondary winding. The advantage of this method of winding is that the magnetization is thereby distributed uniformly, and is enabled to act equally upon all parts of the core.

It will be observed that the function of the first induction coil is to develop alternating currents in the intermediate circuit without raising the potential of such currents. If the potential in this circuit were to be raised, it would be necessary to multiply the convolutions of both the helices included in it, with a consequent increase in cost, in resistance, and in waste of energy. Furthermore, it is of great importance to keep down the resistance of this intermediate circuit, for the reason that in telephony self-induction is a potent factor in opposing the proper operation of the current, and the self-induction of any circuit of which coils or helices form a part is mainly dependent upon the number of their convolutions. Hence, there is special utility in employing a few convolutions of thick wire instead of a greater number of convolutions of thinner wire in the intermediate circuit.

ELECTRIC LIGHT MOLDINGS.

THE introduction of a new industry usually brings with it many collateral branches of new work and in this respect electric lighting constitutes a conspicuous example. Incandescent lighting once proved a practical success, a host of details had to be worked out to fit it for general use within doors, to make it safe against injury to person and property; and added to this safety, a harmony was required with the general surrounding of the premises in which the light was employed. Electric house wiring has, therefore, taken a prominent place in electrical work and certainly deserves most careful consideration for reasons which are obvious.

Electrical conductors run in houses require not only to be thoroughly well insulated electrically, but also to be protected from mechanical injury and from contact with deleterious influences. To effect the latter purpose the electric light molding occupies at the present time an important position. Its main object, of course, is to hold the circuit wires securely in position at the proper distance apart, while at the same time it is required to conform to some extent to the ornamentation of the apartments in which it is run. Imperviousness to moisture is also a great desideratum in this connection. The ready adaptability of wood as material to fill these conditions is obvious, and hence wood moldings have been employed to a very large extent in this class of work. The practice in this country has run largely to the employment of a molding, consisting of a base in which the grooves are cut to the size required and which are covered by a capping set into the base for a small distance, so as to be firmly secured; the nails or screws employed being merely used to hold the cap in place without taking any of the strain.

The various sizes and styles of molding in general use are illustrated in the accompanying chart, and represent those manufactured by Mr. Russell Johnson, of this city, to whose courtesy we are indebted for the use of the chart. While in this country the grooves in the base-boards are for the large part rectangular in character, those employed abroad, and especially in Germany, have rounded bottoms and corners. The practice abroad also is to employ straight cappings, not set into the base molding. The depth of the base moldings below the groove, as will be seen, is also a matter which is quite variable; those on some of the work being furnished by Mr. Johnson for the government cruisers now building are pine beams 4 x 6 inches and have one inch grooves cut in them for the wires, thus leaving 3 inches of solid backing behind the wires. The wood usually employed in this country is pine, though not infrequently poplar is employed for the purpose. The latter is almost universally employed abroad on account of the scarcity of pine there. The general cheapness of wood in this country has indeed made it possible for wood moldings to be profitably exported abroad, and quite a trade has developed in this direction. In addition to the standard sizes of molding which are illustrated in the accompanying chart, a large number of others have been made, to fulfill certain requirements, and we have seen moldings with a dozen grooves to

carry a number of main leads from the dynamo to the points of distribution. The various styles of ornamentation of the caps also provide a field for much variety of design and finish.

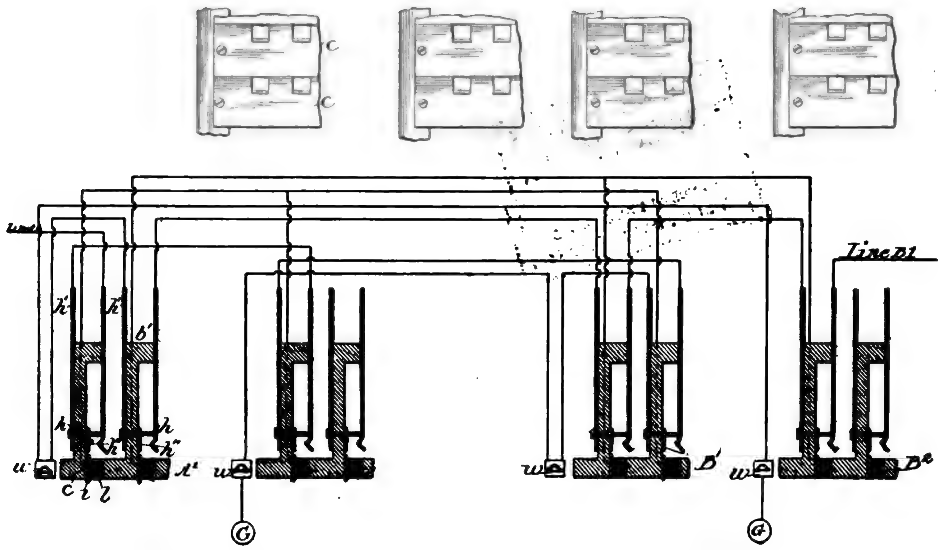
KELLOGG'S NEW MULTIPLE TELEPHONE SWITCH BOARD.

It is well known that multiple switch-board systems and apparatus as at present constructed and arranged become very expensive per line or subscriber where a very large number of subscribers' lines are operated in one multiple switch-board exchange. In these systems there is now usually provided one switch-board for about every 150 subscribers' lines. There is one spring-jack for each subscriber's line which belongs to the exchange. It is, therefore, evident, that, as the number of boards used in an exchange is increased as the number of subscribers' lines is increased, the number of switches for each line is correspondingly increased, and consequently the cost of the switches for a line is similarly increased. The number of switches used in an exchange of 5,000 subscribers' lines will be four times the number of switches used in an exchange of 2,500 subscribers' lines, and the number used in an exchange of 10,000 lines will be 16 times as great. Where more lines are used, the number of switches used per line will increase in like ratio. The number of lines which can be operated in one multiple switch-board exchange is, moreover, limited by the number of the spring-jacks which can be grouped on one board within convenient reach of an operator. It may be stated, approximately, that as the systems are at present constructed the number of lines which can be operated in one exchange is limited to about 10,000.

Recognizing the difficulties attending the service of a large number of subscribers and the great cost of switch-boards, Mr. Milo G. Kellogg, of Hyde Park, Ill., has recently designed an ingenious system by which he reduces by one-half the number of spring-jack switches which are required at each board, thus effecting a large saving in the cost of apparatus, and at the same time practically retains all the advantages which have heretofore been obtained in the multiple switch-board systems employed. The manner in which this is carried out will be apparent from the accompanying engravings. Here Figs. 1 and 2 represent a front and sectional view of several sections of the switch-board. This is so arranged that when a switch-plug is inserted into a switch-hole it raises the spring-lever in the rear of the hole from the contact-point on which it normally bears, and the flexible cord of the plug is connected with the spring-lever, while the contact-point and the contact-piece *i* of the switch are electrically connected through the medium of the switch-plug, which then touches both *i* and *h''* of the switch.

The calling annunciators or signal-receiving instruments, *w*, one for each line in each of the two sections of the exchange, are located at the boards where the calls of their lines are to be answered. These annunciators are polarized and their construction is shown in detail in Fig. 3. Each of these annunciators responds when one polarity of current passes over its line and does not respond when the other polarity of current passes over the line.

The apparatus at the subscriber's station is shown in Fig. 4. The generator is constructed with the usual automatic device, whereby it is shunted or switched from the line-circuit while not operated. The insulated contact-piece on the shaft of the armature, to which is connected one end of the armature-wire, and which conducts the generated current to the line through the stationary spring-contact provided for it, is a half-circle, the remaining part of the circle being of insulating material, as shown in Fig. 5. There is also provided a calling-key, *k*, with two pairs of contact-points, one pair being normally closed and the other pair normally open, and when the key is depressed the normally-open pair of contacts is closed and the normally-closed pair is opened. The connection of the key to the contact-springs of the generator and to the line-circuit is as follows: The spring-lever, which forms one of the contacts of each pair of contact-points, is connected with one side of the main-line circuit. The two other contact-pieces of the pairs of contact-points are connected to the two contact-springs, respectively.



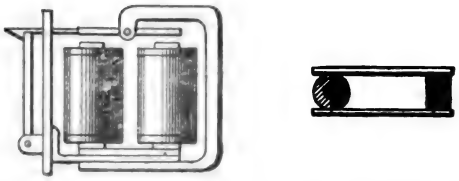
Figs. 1 and 2.—Kellogg's New Multiple Switch-Board.

Now, it is well known that when magneto-generators are operated a current of one polarity is generated during one half of the revolution of the armature and a current of the other polarity is generated during the other half of the revolution of the armature. It will, therefore, be apparent from the description of the subscriber's station apparatus which has been given, and from the circuits, that when the generator is being operated and the key remains in its normal position the armature-wire is in circuit through one only of the contact-springs, and a current of one polarity will be sent to the line; and that when the generator is being operated and the key is depressed the armature-wire is in circuit through the other contact-spring, and a current of the other polarity will be sent to the line. The subscriber can, therefore, at will send currents of either polarity to line, as he does not or does press on the calling-key. When his line is provided with two calling annunciators which respond to currents of opposite polarity, as shown,

one annunciator being located at a board in one section of the exchange and the other annunciator being located at a board in the other section of the exchange, he can at will call the operator at either board and not disturb the other operator.

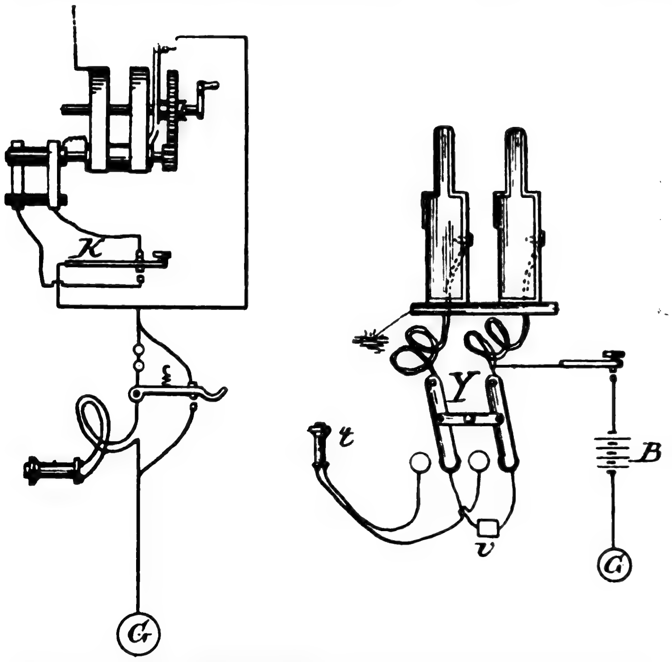
The operator's cord system, shown in Fig. 6, has a pair of cords with switch-plugs, a calling-key, a looping-in switch, and a clearing-out annunciator, and the usual telephone and calling-generator.

To carry out the organization it is necessary that each subscriber should be able to determine whether or not he is



Figs. 3 and 5.—Annunciator and Insulated Spindle of Magneto.

to press his calling-key when he calls for connection with any other subscriber. To accomplish this the subscribers whose lines belong to one class are indicated by some designation in the exchange list—as, for instance, their numbers may all be prefixed by the letter A. The subscribers which belong to the other class may also be designated in some manner—as, for instance, by the absence of any prefix or special mark. All the calling-keys are marked with the letter A. The apparatus and lines are so connected that when a subscriber desires connection with any line designated by the letter A he operates his generator while pressing on his calling-key marked A. When he desires



Figs. 4 and 6.—Subscriber's and Operator's Apparatus.

connection with any line of the other class, he operates his generator without pressing on the calling-key. This system of calling either board at will to which the subscriber may be connected therefore requires but one calling-key, and it requires the subscriber to press on the key only when he is calling one board.

It will be seen from the description of the main-line circuits and apparatus and of the operator's cord system that when two subscribers' lines are switched together at any board of the exchange by the insertion of the two plugs of any pair of cords into the switches of the line at that board the two calling-annunciators of each line are cut off or disconnected from the circuits of the line, and the operator may, by the use of the switch, Y, in Fig. 6, loop the clearing-out annunciator, *v*, into the combined circuit of the lines. The number of pairs of cords needed for the system will depend on the number of connections which are liable to be required at one time in the exchange. As a general thing one pair of cords to every eight or ten subscribers' lines will answer.

THE NEW TELEPHONE EXCHANGE, HARTFORD, CONN.

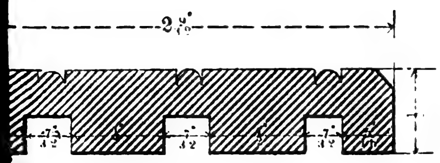
In the early days of telephony, exchanges were situated in the most convenient building available at the time, but the rapid increase in the number of subscribers which followed soon made such quarters not only inadequate of accommodation but developed inconvenience when the later improvements which were brought about were adopted. As a result the more progressive telephone companies have undertaken the erection of building specially adapted to exchange purposes, and some of these structures now rank among the finest buildings in our large cities.

Among such structures recently erected is the Telephone Building, at Hartford, Conn., built by the Southern New England Telephone Company. The building, which is shown in perspective in the accompanying engraving, Fig. 1. is situated on the southeast corner of Pearl and South Ann streets, on a lot fifty feet on Pearl street and running back about one hundred and twelve feet on South Ann street. The building occupies the entire Pearl street front and some seventy-eight feet of the depth of the lot. It is built of brick with granite and brown stone trimmings, and is most substantial in its construction. It is constructed on the slow-burning system; that is, the floors are of the beam and plank description, with protecting layers between the planking and the upper flooring, and the partition walls are of terra-cotta lumber, in place of scantlings.

On the ground floor are two stores, running the entire depth of the building, which are entirely separated from the other parts of the building by brick walls. The second story floor is to be of plank, covered with an inch of fireproofing material, and on top of that the flooring proper. It is on this story that the business of the company is to be done. The business office will be in the corner room on the front. This will be the local manager's headquarters. A feature of this room will be the cabinets for the use of telephone users. On one side of the office will be built two cabinets, enclosed by plate glass, and made sound-proof, in which will be Long Distance telephones and all the conveniences for conversation with any of the cities that are connected with the Long Distance lines. The talker will be entirely protected against interference from outside noises, and also from being overheard while talking.

Across the entire rear of the second floor runs the operating room, as shown in the plan, Fig. 2. It is well lighted from the south and west, and is large enough to accommodate a switch board for three thousand subscribers. Adjoining the operating room is a parlor and toilet rooms for the young women who are employed in the room, well lighted and comfortable.

Between the operating room and the hall is the critical point in the exchange, the distributing room. This is the room into which all the wires of the system come before passing to the switch-board. The room is to be as nearly fireproof as the character of the building will permit. The walls are brick and terra cotta, the ceiling is metal lined, and the floor is asphaltum. One of the features of the room is this floor. It is waterproof as well as fireproof, and is graded to a scupper that leads to the shaft, so that it can at any time, in case of a sudden fire among the wires, be flooded with water without injury to the remainder of the building. On the outer side of the room will stand the distributing board. This is of a new design, the work of Mr. George A. Milliken, the electrical mechanic of the company, and Mr. E. B. Baker, the general superintendent. It is of Russia iron, with room for 1,000 pairs of



A 7

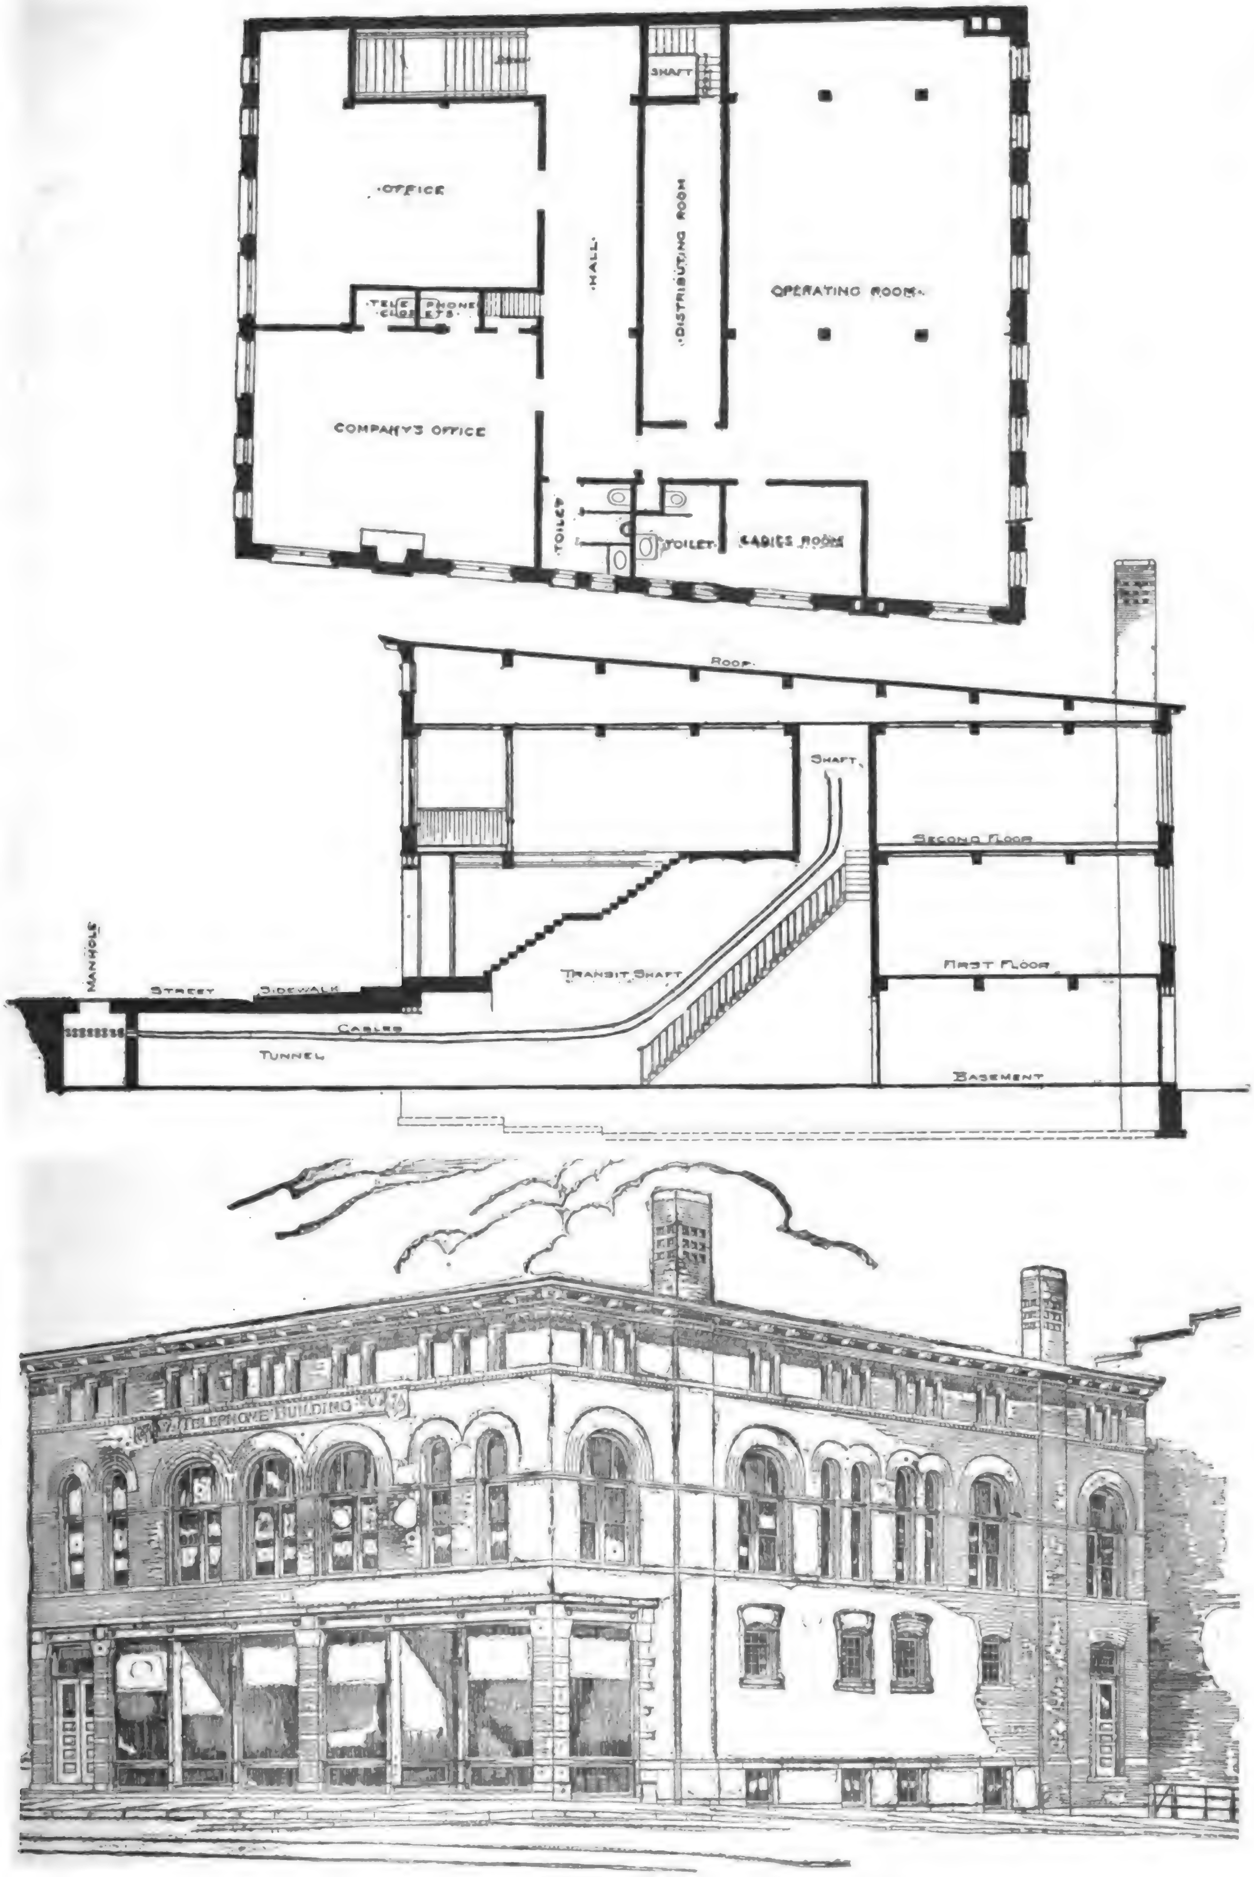
C 2



FIGS. 1, 2 AND 3.—THE NEW TELEPHONE EXCHANGE, HARTFORD, CONN.

(L. W. Robinson, Architect, New Haven, Conn.)

wires. It is in the form of a series of upright channels of sheet iron, bolted and riveted together, on one side of which the wires enter from the cable heads, that are just above it, and from the other side of which the wires run to the switch-board cables.

The switch-board is to be of the latest pattern of the multiple type, like that now in use in the company's building at New Haven, arranged for metallic circuits. It will have an ultimate capacity for more subscribers than the exchange will probably have in twenty years. Its cost is $5,000.

The feature of the building that the company takes the most satisfaction in is the manner in which the wires are brought into it.

The roof of the new building will not have a wire upon it. Everything is brought in from the underground ducts. On the east side of the building is a stone stairway, as shown in the section Fig. 3, enclosed in heavy brick walls. Under this stairway is a brick and cement walled passage, leading from the man-hole in Pearl street up to the floor of the operating story. Here the passage becomes a tight brick shaft, to the attic floor, and is there ended in a heavy flagging. It is through this passage that the cables of the company will be brought to a terminal board. At some distance back of the stone stairs, which form the principal entrance to the operating department, is a staircase of iron, running from the second story and opening into the terminal room, down to the floor of the fireproof passage, on a level with the cellar floor. The cables will be hung on the walls of this fireproof passage, and by means of this iron staircase will be within reach of the hand for the entire distance from the terminal room to the man-hole in the street. This is considered of the highest importance to the safety of the exchange.

This building, when completed and occupied, will have cost the company, with its equipment, over $40,000. The architect of the company is Mr. L. W. Robinson, of New Haven, and the contractors are Messrs. Whiton, Porteus & Co., of Hartford. It is expected that the building will be occupied in October.

But this central station is not by any means all that the telephone company has built in Hartford this year. It has commenced an entire revolution of its system of construction and of operation. Hitherto the business has been done on the grounded system, but for the new work the metallic circuit system will be adopted throughout. For the central masses of wires the underground conduit is used. The company has laid this summer 75,000 feet of underground duct in Hartford, and is preparing to connect all its wires with the outer terminals of the seven miles of cables that it has already drawn into these ducts. Some idea of the amount of work that has been done will be had when it is stated that there are now under the surface of the streets in Hartford more than 500 miles of insulated wire, and that when the work is completed there will be more than 700 miles. The cables used in Hartford are of the Faraday pattern, made by the American Electrical Works, at Providence.

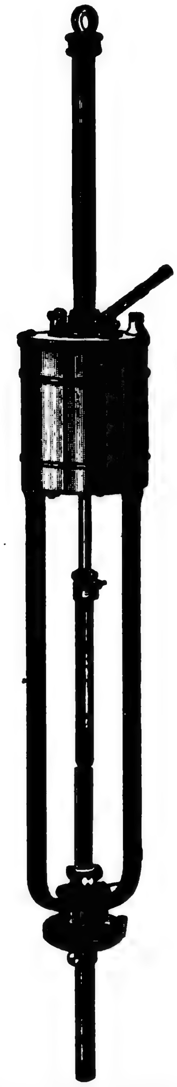
The underground ducts are of the Phipps cement lined iron pipe, laid in a matrix of cement, and running into man-holes at the corners of the streets. The man-holes of the company are all six feet square on the inside, built of twelve-inch brick walls, laid up in cement, and topped with heavy cast-iron covers. From these man-holes the cables are led through lateral ducts to the upper part of the company's poles, where they enter cable boxes and are distributed, as needed, to the subscribers.

In addition to the underground work this change of system involves an entire renewal of the overhead construction of the exchange, and this is now going on, the specifications being of the most approved character. The wires are of copper, there is a free use of cables and covered wire in difficult or dangerous places, and the equipment of the subscriber's station will be largely new. This work, aside from the building, will cost the company $60,000, or more, so that its total expenditure in this one place this season will be a good deal over $100,000.

THE NEW SPERRY TRIPLE CARBON ARC LAMP.

Among the novelties which attracted considerable attention at the late Cape May Convention was the new triple carbon arc lamp of the Sperry Electric Co., of Chicago, which was in operation on the circuit of the local electric light company.

The new lamp, which is illustrated in the accompanying engraving, consists of two ordinary circular carbons, which are clamped side by side in the upper holder of the lamp.



The Sperry Triple Carbon Arc Lamp.

This holder is a modification of the old single carbon form, so constructed as to firmly hold the two positive carbons in position. The lower carbon is a single flat piece with rounded edges, and only half the length of the upper carbons, as in all ordinary lamps, but of practically the same cross section as the two upper ones.

The play of the arc is quite interesting. Thus it starts between one of the upper carbons and the lower, and as it increases in length by the burning away of the carbon, it instantly jumps and forms between the second upper carbon and the lower, and so on. These alternations of position, however, are indistinguishable to the eye; and the lamp burns with the utmost steadiness.

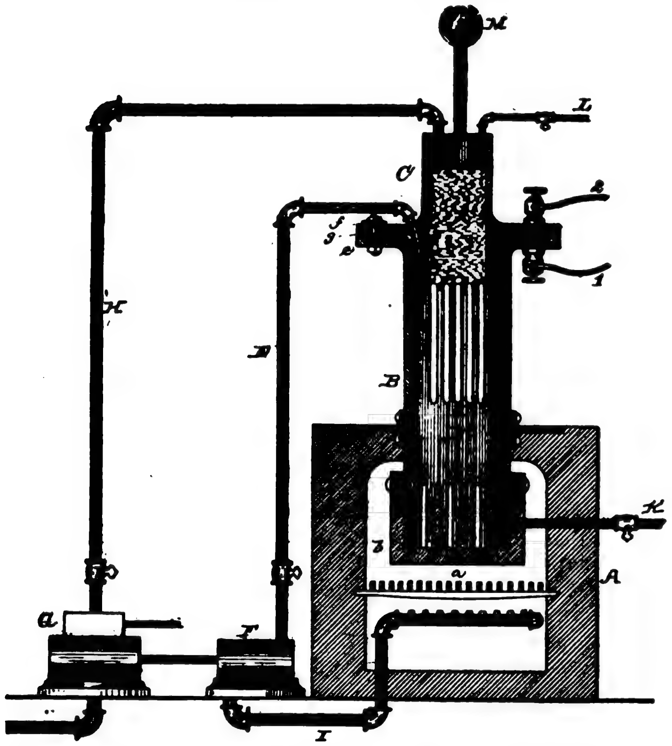
The clamp which holds the lower carbon is rectangular

in shape, substantially that of the carbon itself, and is fitted with adjusting screw and clamping piece, so as to always bring the carbons in line.

EDISON'S NOVEL GASEOUS GENERATOR.

The fertility of Mr. Edison's inventive genius cannot be better demonstrated than by reference to the numerous methods proposed by him for the generation of the electric current. In our last issue we had occasion to refer to two such methods proposed by him, and we would now call the attention of our readers to another, which, even if not likely to come into general use, is nevertheless quite interesting.

Electricity has been generated heretofore by chemical reactions in liquids, which acted as the conducting media, but Mr. Edison proposes to generate electricity by dry chemical reactions, and to use the gases liberated as the conducting media of the generating apparatus. This he is enabled to do by causing the dry chemical reaction to take



Edison's Gaseous Electric Generator.

place in a vacuum-chamber in a rarefied atmosphere forming the conducting medium, and in the presence of heat which maintains the chemical reaction and increases the electrical conductivity of the rarefied gas. Such compounds or compounds and elements are used that, under the conditions of heat and rarefaction employed, the chemical reaction which takes place within the inclosing-chamber will produce a solid or liquid, that is, a non-gaseous product, which remains at the point where the reaction takes place, and will liberate a gas which rises into the chamber. The inclosing-chamber being electrically divided into two parts, which form the poles or current-collectors of the apparatus, the non-gaseous product remains upon and charges one pole while the gaseous product charges the other pole. There is kept up a continual exhaustion of the chamber to maintain the proper degree of exhaustion as the reaction takes place.

A form of apparatus designed by Mr. Edison, in which these reactions could be carried out, is illustrated in the accompanying engraving. A tubular vessel B is supported on a furnace A, and on the bottom plate *b* are fixed upwardly projecting iron rods *c* which act as electrodes. The vessel B supports a steam boiler, C, the water tubes, *d*, of which project downwardly. It will also be noted that the two vessels are insulated by the asbestos packing *g*. The boiler closes the top of the vessel, forming a reaction chamber D, in which the chemical reaction takes place. Entering this chamber is a pipe E extending to the inlet of the air pump F; the latter is operated by the engine G which takes steam from the boiler. A pipe I extends from the outlet of the air-pump to the fire box of the furnace, and another pipe K admits water or steam to the chamber D. The circuit connections are made between the two vessels as shown.

A great variety of compounds or elements may be used in producing the chemical reactions described, since nearly all chemical reactions produce electricity under the proper conditions. A reducible or oxidizable substance can be employed, such as a metal or metalloid, acted upon by a gaseous, liquid or solid compound containing an element with which it will readily combine when the compound is decomposed; or a non-metallic material, like carbon, might be employed instead of the metal or metalloid.

An efficient method is to use a metal, such, for instance, as iron, in a divided condition, which is placed in the chamber and brought up to incandescence, and then to permit steam or water in the proper quantities to enter the chamber. The oxygen of the watery vapor will combine with the metal, and the hydrogen will be liberated, the chemical reaction setting up a current of electricity, the rarefied hydrogen charging one pole, while the other pole is charged by the iron. The operation is a continuous one until the metal is oxidized, the heat being kept up and the steam or water being permitted to flow into the chamber in a continuous jet.

Carbon in any form colud also be conveniently employed, such as charcoal, coke, lamp-black, or anthracite, or other coal mixed with a reducible oxide of a metal. Oxide of lead might also be mixed with carbon and placed in the chamber. As the heat is raised the oxygen of the oxide of lead will combine with the carbon, producing carbonic oxide and reducing the lead to the metallic form. The rarefied carbonic oxide passes into the chamber and charges one pole, while the metallic lead charges the other pole.

The hydrogen or carbonic oxide withdrawn continuously by the vacuum apparatus can be forced into the fire-box and burned as fuel for heating the chamber; or, where the gas is suitable for the purpose, it can be used for producing chemical reactions in other vacuum-chambers. Carbonic oxide, being a powerful reducing agent, is especially adapted for this purpose, and as withdrawn from one chamber could be used to reduce a metallic oxide in another chamber.

The chemical reactions in the apparatus can also be reversed, if desired. Thus metallic iron could be oxidized by admitting water or steam to the chamber, producing currents of electricity, and then charcoal could be placed in the chamber and the oxide reduced to a metallic form; or this could be done by the admission of carbonic oxide, this reaction also producing currents of electricity. The metallic iron may then be again oxidized, and these operations may be repeated indefinitely, the waste of the metal or oxide being made good, as found necessary.

THE BRITISH ASSOCIATION MEETING.

The British Association for the Advancement of Science held its annual meeting last week. Sir Frederick Abel, the president, in his address from the chair, made a survey of the strides of modern discovery and invention. He dwelt upon the use of electricity for motive purposes, as exemplified so remarkably in America, while England has been slow in this respect.

THE LECHNER ELECTRIC MINING MACHINE.

A trial of the Lechner electric mining machine, which is manufactured at Pittsburgh, was made at the Boston, Pa., coal mines of Capt. S. S. Brown recently. A number of gentlemen witnessed the work of the machine and were highly pleased. In five minutes a solid piece of coal three feet wide and four feet and a half deep was cut through. Captain Brown has been paying a good deal of attention to this machine lately, and will introduce it in all his coal works in the near future.

THE SWINBURNE "HEDGEHOG" TRANSFORMER.

LAST year Mr. James Swinburne brought forward the theory that an open iron circuit could be made more efficient than any form of closed iron circuit transformer. The loss in a transformer, he argues, is made up of loss in copper due to resistance, and loss in iron due to hysteresis. In calculating the efficiencies of transformers, the loss in the iron has generally been left completely out of account, and the loss in copper alone considered ; hence, the efficiencies of 97 and 98 per cent. claimed for closed iron circuit forms. If the loss by hysteresis is taken into account, allowing the losses as given by Ewing, the loss in iron in closed circuit transformers, as usually designed, is some 10 per cent. of

FIGS. 1 AND 2.—SWINBURNE'S "HEDGEHOG" TRANSFORMER.

the full load. As the loss in iron goes on all the time a transformer is in circuit, this is very serious. The proportion of actual to possible output of energy per day varies in different districts, but in most stations the average use of lamps is less than two hours a day, including all lamps installed. The transformer must be large enough to feed all the lamps installed, so it runs, say, on an average two hours at full load a day. If there is a loss of 10 per cent. at full load in the iron, this gives an actual efficiency of 45.5 per cent., even neglecting the loss in copper.

In the "hedgehog" form the proportion of iron is very much reduced. The cross section of the iron is much less, and the length is about one-third of that of the closed circuit form, as it has not to surround the wire. The result is that even in small transformers the iron loss is under one per cent. of the full load. One per cent. of the full load gives 89 per cent. all day efficiency, neglecting copper loss, against the 45 per cent. of the closed circuit. This is neglecting copper, however, and the copper loss is greater in the "hedgehog" form, so this is an exaggerated comparison. Such a transformer in reality, according to Mr. Swinburne, has an efficiency of about 87 per cent. all day.

The theory of the "hedgehog" form is this : If a closed iron circuit is used, the iron circuit must be long to embrace the copper coils. The only way to shorten it is to make the copper coils smaller. This means using a higher current density, which is wasteful, or fewer turns of copper. Fewer turns of copper demand either a higher induction in the iron or a greater cross section, and either of these means greater loss by hysteresis. If the iron circuit is opened, the sides of the embracing core can be removed, so the loss by hysteresis is divided by three. As there is now plenty of room for the copper, the turns and cross section can be increased and the iron reduced still farther.

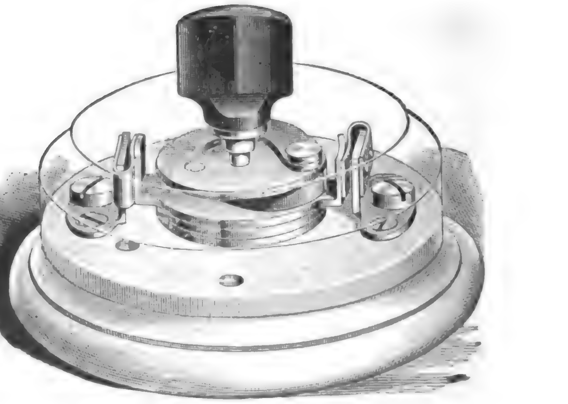
The object of introducing the closed iron circuit was to reduce the magnetic resistance. An open circuit transformer has much higher magnetic resistance, but, according to Mr. Swinburne, the question of magnetic resistance is not so important as might at first sight appear. Its increase demands more excitation, or more magneto-motive force, and this increases the loss in copper. The best form is thus a compromise, and the "hedgehog" ends are employed to reduce the magnetic resistance. In a conductive circuit the resistance is low if the current density is low in all parts where the specific resistance is high. Similarly, in a composite magnetic circuit of iron and air, the magnetic resistance is low if there is never a high magnetic current density or induction in the air, which has high specific magnetic resistance. The magnetizing current in a "hedgehog" is high, but as it is a quarter of a period behind the primary current in phase, and as the primary wire has to be large enough to carry the primary current, the loss in watts is small. As this loss goes on all day, however, it is by no means unimportant, and has to be included in getting out the efficiencies of these transformers.

The construction of these transformers as carried out by Messrs. Swinburne & Co., of Teddington, England, is very simple. A gun metal casting of cross shaped section forms the backbone. It is spread out at each end, forming legs at one and taking the circular terminal board at the other. It also carries insulating flanges, which form the ends of the coils. Into the four recesses of the core are put four bundles of soft iron wire. These are taped over, and the secondary is wound on. The secondary is then covered with two layers of ebonite, and the flanges are also faced with the same material. The primary is then wound on in two compartments separated with ebonite after the manner invented by Gramme, so that both ends come outside, and as far removed from each other as possible. The ends of the core are then spread out, as shown in Fig. 1, and the transformer tested under 4,000 or 5,000 volts, the insulation in megohms being read by a peculiar instrument which measures the effective resistance under an alternating current.

Iron cases cannot be used, as they would be magnetized by the transformer ; and, as any metal would have Foucault currents generated in it, stoneware jars are used for cases. These have lids bolted down, with holes for the leads, as shown in the engraving, Fig. 2.

THE HART SNAP SWITCH.

AMONG the novelties shown at the late Cape May convention was a snap switch designed by Mr. Gerald W. Hart, superintendent of the Edison Electric Light and Power Co., Kansas City, Mo. The switch, which is illustrated in the accompanying engraving, is so constructed that it performs a rotary movement in one direction by quarter turns, and snaps full on, or off, without being able



THE HART SNAP SWITCH.

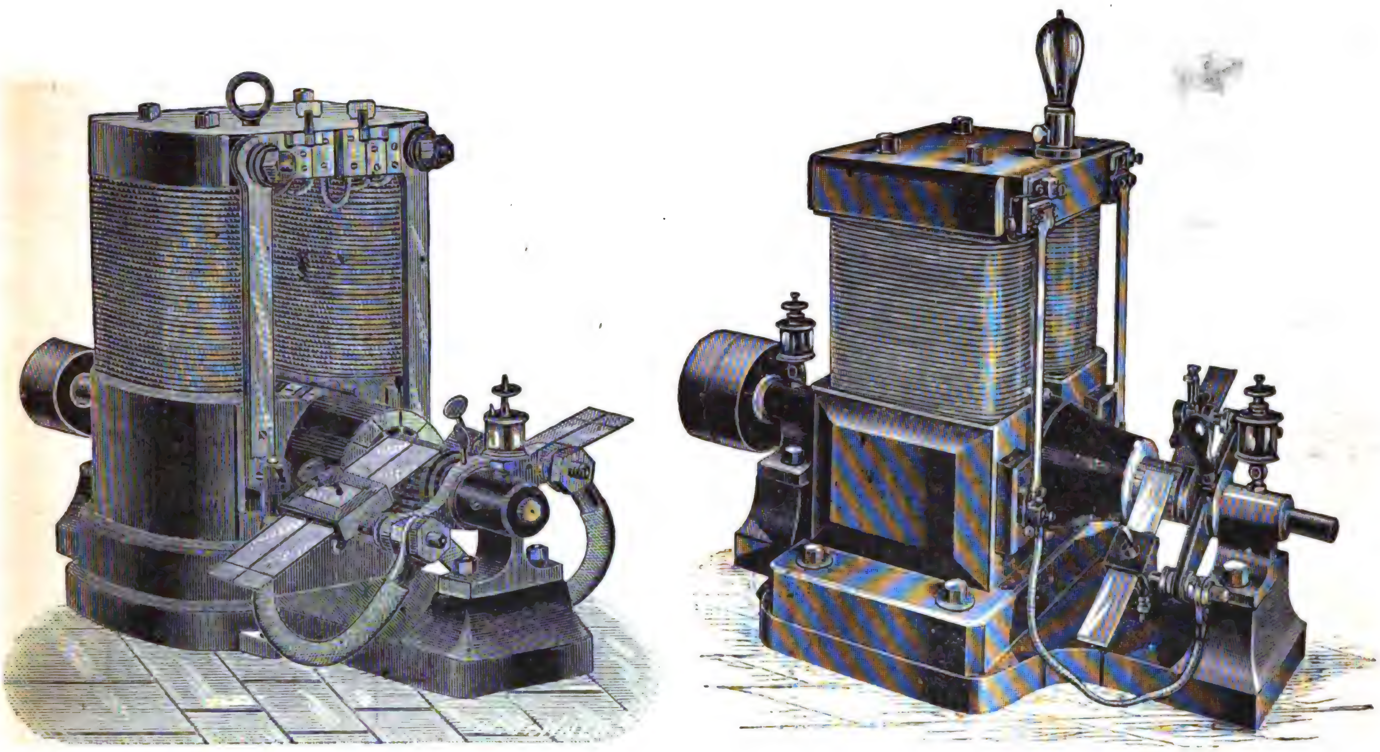
to stop at any intermediate position. This is accomplished by the employment of a curved steel spring, which accumulates tension as the switch knob is turned and is then suddenly released and moves the contact independently of the switch knob.

As will be seen, the current entering at the spring contacts passes into the connecting piece, which is of large surface and of ample carrying capacity, and the current is not required to pass through any pivots or springs. The

break, of course, is a double one, and the breaking distance very large for the size of the switch, so much so that it can be used with impunity on a 500 volt circuit. The engraving shows the 10 ampere switch in full size. The switch is now being manufactured by the Hart & Hegeman M'f'g. Co., of Kansas City, Mo.

THE KING DYNAMOS.

Among the recent additions to the dynamo machines now being built, are those of the Detroit Dynamo Co., of Detroit, Mich., which have been designed by their electrician, Mr. W. R. King. The dynamo intended for electroplating is illustrated in the accompanying engraving, Fig. 1. In this machine the perfect electric balance maintained in the armature prevents all sparking at the commutator. By the method of construction adopted and by the use of compound winding, the electromotive force of the machine is kept practically constant at all loads, so that the quality of the work is independent of the amount



Figs. 1 and 2.—The King Electro-Plating and Incandescent Dynamos.

of pieces in the bath. Besides making the use of a separate exciter unnecessary, the reversal of the machine is also prevented by the construction adopted.

The incandescent machine built by the same company is shown in Fig. 2, and is also entirely automatic in its regulation, maintaining potential constant, whether one lamp is in circuit or the full load is on the machine. The voltage of the machine is such that arc as well as incandescent lamps can be placed directly on the circuits. These machines have been installed in a number of works in Western cities.

A LOCOMOTIVE RUNS DOWN AN ELECTRIC CAR.

At Cleveland, O , on Sept. 6, a bad accident occurred on the Williston avenue electric road, an electric motor car and trailer being run into by a locomotive at a crossing. No warning had been given of the locomotive's approach. A woman was killed and twelve persons were injured in the collision.

ELECTRIC RAILWAY STRIKE AT WHEELING, W. VA.

The electric railway service at Wheeling has been suspended for several days owing to a strike. The tracks have been obstructed and the police have refused to man the cars.

HOW THE INTEREST MAY BE INCREASED IN A SCIENTIFIC SOCIETY.

BY J. P. WINTRINGHAM.

The primary idea of a scientific society is that the speakers shall bring before it some new discovery or invention or principle. But the field having been pretty well covered at this age of the world, at least as far as the more elementary matters are concerned, it becomes a task that few have the ability to accomplish. You can hardly expect to have the services of those who have this ability unless the society publishes its transactions.

A second object of a society may be considered to be to show in detail the various methods of doing all classes of work that comes within the scope of the society. Not that others do not know how to do the same thing, perhaps as well or better, but because each one is likely to have some novelty about some of the details of any operation that is superior to the more common method.

It would, I believe, be an attractive feature to any such society to have all new experiments repeated before it. If the society had to buy the apparatus for such work it might be very expensive, but doubtless amongst the many members a large part of the apparatus might be found, unless the new experiment involved novel apparatus. The want being understood, no doubt the members would offer to allow the society the use of such as they have, and often dealers would be glad to exhibit novelties. I believe there is a society in England that has this idea for its object (Experimental Society).

I am inclined to recommend that the society should have each alternate meeting devoted to a systematic course of lectures or studies, beginning with the elements of the subject and carried as far as time allowed. Not that we should have some master present the subject to us in its entirety, but that some member should offer to write out a fair presentation of the subject of the evening, or should take from some published essay or text book that part wanted, to occupy half an hour to an hour's time. The main feature to be a full, thorough discussion by the members of every obscure point or part little understood. Or, to put it differently, to have the members compare their

various conceptions; for some would have perfected and elaborated their ideas so much more than others that it would be to our great gain to know what they thought. I might instance the attribute Mr. Mailloux gives to the magnetic lines of force. I believe the conceptions of most of us are flat and often narrow, rather than full and rounded, as they should be. And they can perhaps only be perfected by contact with the views of others.

The ordinary reading of papers does not allow much chance for discussion, because only the writer knows what is to be presented, and others cannot be prepared to make a reply except on the spur of the moment.

I think every scientific society should arrange to have notices of its meetings, and, if possible, the subject of papers coming before it, appear in appropriate periodicals under the head of a diary. It would increase the attendance and also would encourage those who prepared papers to be read.

THE NEW "LAW" SWITCHBOARD FOR PHILADELPHIA.

The Bell Telephone Company, of Philadelphia, have recently erected a new building of their own at 406 Market street, in that city, running through to Merchant street. It is 35 feet wide with a depth of 119 feet from front to rear. It is four stories and basement in height and each story is of unusually lofty pitch, so that the edifice is really as high as many buildings that boast nearly double the number of stories. The building is occupied exclusively by the Telephone Company and was designed with a single eye to their use. It is fire-proof in every sense of the word; in the basement is a remarkably complete plant for lighting, heating and ventilating, and the conductors enter underground from a system of conduits that ramifies throughout the whole city. This system, it may be mentioned incidentally, is partly of iron pipe and partly of "indurated pipe," the latter of which has received Dr. S. M. Plush's enthusiastic praise. The blocks of buildings in Philadelphia are intersected by narrow lanes. In each lane is placed a distributing pole to which the conduit runs. The cable is carried thence up the pole in a pipe and the services are taken off for each subscriber in the block.

Coming back to the exchange, we find the cables passing in from the street through a large tunnel. The cables are carried up some distance, pass to the lightning arresters, thence to the distributing or cross-connection board and thus at last to the new switchboard.

The Law Telephone Company, of this city, are building the board or table, and expect to have it in operation by November. Its cost will reach not far from $100,000, and it will have a capacity of 10,000 subscribers. It will be in 30 sections, each having a capacity of 10,000 subscribers, and each accommodating two operators. The board is being wired up on the metallic circuit plan, and the whole of the 10,000 metallic circuits go into a space 30 inches wide by 36 inches long. This seems incredible, but "seeing is believing." At the start the board will be fully wired up for 6,000 subscribers. Much ingenuity has necessarily been shown in this economy of space and material, but owing to the exigencies of patent questions, we can only just hint at a few novel details. One peculiar feature is that in building up the sections, which look for all the world like slices of square black honeycomb, the rubber has been vulcanized on the metal parts of the board instead of being rivetted or screwed on as heretofore. This is quite new in the art and proves very successful. A second special feature is the weaving of the wires in a broad flat band, and carrying them through the board in that shape. A third feature is that of fastening the wires to the sockets by pinning or pressure, instead of soldering or screwing. Another feature has been the provision made by square chambers, lined with aluminum in place of brass for maintaining the sliding contacts for the operator's plugs. Yet another new departure has been the use of iron for the framework of the board, giving economy in more than one direction. All told, Mr. Childs says, the gain in space as compared with what has been done before is so great that not a quarter as much will be required. It is claimed that in the boards, of which the most conspicuous example is illustrated in this issue of The Electrical Engineer, it is impossible to bring even 6,000 multiple connections within reach of the operator; whereas, here are found 10,000 bunched for most comfortable and convenient handling.

The Reed's Lake Electric Railway, Grand Rapids, Mich. (See page 285).

"Laying Ocean Cables."—The article on this subject by H. L. Webb will, it is now announced, appear in the October *Scribner's Magazine.* It will be the leading illustrated article.

THE REED'S LAKE ELECTRIC RAILWAY.

One of the more recent electric railways which has made a record for itself is that just installed at Grand Rapids, Mich., by the United Electric Traction Co., of this city. The Reed's Lake Electric Railway, as it is called, is 2¾ miles in length. It was started on August 6th, and has been since in successful operation. The motors are the company's new standard 30 h. p. type, and propel the cars at an average speed of 18 miles per hour, with maximum gradients of 3½%. There were 197 passengers on the two cars when the picture from which the accompanying cut was made was taken. The greatest number of passengers carried as one load, so far, is 223, and the greatest number hauled in one day with one motor, 2,331. The average daily run of each train is 105 miles. The motor cars are 26 feet long, and the trailers are 35 feet over all. Each motor carries one trailer.

Great credit is due Mr. V. H. Yarnall of the U. E. T. Co., who superintended the construction of the line.

The station outfit consists of two Mansfield Machine Co.'s boilers, one Taylor 100 h. p. engine, three 50 h. p. U. E. T. Co.'s compound dynamos (one reserve) and a very complete switchboard.

OBSERVATIONS ON CURRENTS ORIGINATING IN AERIAL TELEGRAPH CONDUCTORS.[1]

BY A. R. BENNETT.

USERS of telephones connected by single wires are familiar with the variety of noises which are generally present even when the line is only a few hundred yards long. It is difficult to find a wire which can be said to be even approximately silent at all times. The origins of some of the foreign currents, which the presence of these noises indicates, have been explained by Preece, Lockwood and others.

Recently in a test of some overhead copper and iron wires, stretched upon the same poles, for capacity by charge and discharge, using a sensitive reflecting galvanometer, the presence of currents which could not be accounted for by any accepted explanation was noted, and investigation was commenced.

It was noticed that soon after the commencement of rain, a

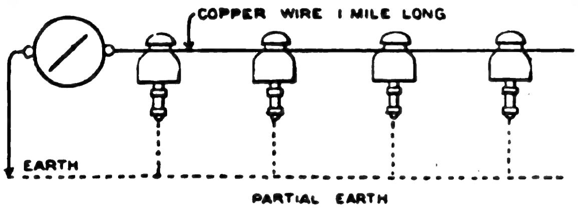


FIG. 1.

steady current appeared in all the wires under test. The deflections increased as the rain continued, until, after the thorough soaking of several days of storm, they were in some cases no longer within range of the scale. A constant discrepancy in the behavior of copper and iron wires was apparent. The deflections from the copper were always positive, while those from the iron were always negative, and as invariably much feebler, seldom exceeding one-third the strength of the positive ones.

To ascertain the cause, two wires, one No. 12½ copper, and the other No. 11 galvanized iron, run side by side on the same arms for the distance of a mile (Fig. 4), were taken. In fine weather the insulation resistance of each was infinite.

When disconnected at the farther ends and earthed at the home end through the reflecting galvanometer (Fig. 1), they always in wet weather exhibited the phenomena described.

The following are extracts from the records of tests extending over several months, during medium and heavy rain :—

Copper.—Always positive.		Iron.—Always negative.

1. Abstract of paper read at the special meeting of the Institute of Electrical Engineers, held in the Lecture Hall, Edinburgh International Exhibition, July 15, 1890.

It will be observed that the copper deflections were always from three to six times stronger than the iron ones. When the copper and iron wires were left insulated at their distant ends, and looped through the galvanometer (Fig. 2), earth being excluded, the positive and negative deflections were always equal. Thus, taking the last three of the foregoing tests, when looped 46 + 17.5 — became 35 + 35 — ; 22 + 7 — became 12.5 + 12.5 — ; 14.5 + 3.5 — became 9.7 + 9.7 —.

Half a dozen insulators with galvanized iron bolts were mounted on an arm in the testing room, and thoroughly wetted

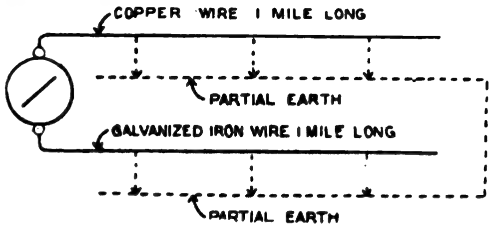

FIG. 2.

(Fig. 3). With a copper wire run on them, and the bolts connected, as shown, a positive current appeared as soon as a film of water was established between the wire and the bolt. With an iron wire instead of the copper no current appeared.

The positive current, therefore, seemed to be due to voltaic action between the copper wire on the insulators and the galvanized iron bolts supporting them when connected with the moist surface. The course of the current can be traced in Fig. 1. The wire and insulator bolts form a series of voltaic cells joined in parallel.

The absence of a current from the iron when mounted on the experimental arm confirmed this conclusion, since no current was

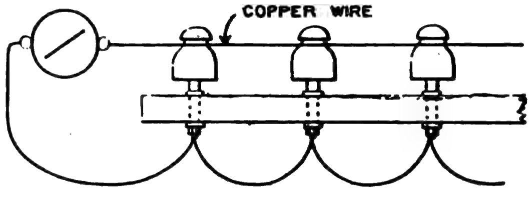

FIG. 3.

to be expected under the conditions. But whence, then, the negative current from the iron wire run on the actual poles? In that case it had a copper wire strung alongside it (Fig. 4). The wetting of both insulators established the connection necessary for electrolytic conduction between them, so that the metals constituted a voltaic couple, the negative current from which appeared on the iron.

The positive current on the copper was consequently due to the copper wire acting with the iron bolts of its own insulators, the iron bolts of the neighboring insulators and the iron wire which they supported.

The negative current on the iron was due to the iron wire, its

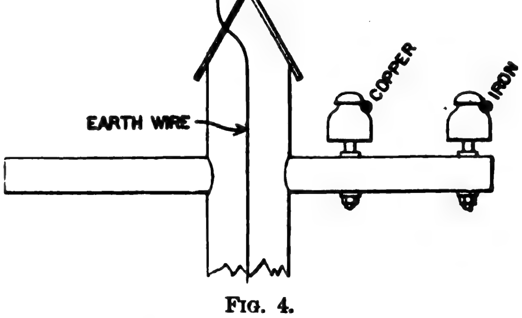

FIG. 4.

bolts, and the bolts of the neighboring insulators, acting with the copper wire. But the bolts of the insulators (Fig. 4) were partially earthed by the damp wood of the poles and the earth wires which ran down them. If the earth had been perfect no current could have got to the galvanometer, but since it was only partial some found its way by that route; and so the difference in strength between the positive and negative currents is accounted for.

The positive, depending chiefly on the action between the copper wire and its own bolts, between which no earth intervenes, is necessarily stronger than the negative, which depends wholly on the action between the iron wire and bolts and the copper wire between which a partial earth is interposed (Fig. 5). So when the earth is cut off from the galvanometer (Fig. 2), the effect of the

earth between the two plates is neutralized, and the positive and negative deflections become equal.

A somewhat unexpected effect of the recent introduction of copper wires for telegraph and telephone purposes is consequently the establishment over the country of a vast number of voltaic couples, which only become operative in damp or wet weather.

The zinc of the bolts of insulators carrying copper and bronze wires may reasonably be expected to disappear sooner than in days gone by, when only iron wire was used; and when copper and iron wires are run on the same poles the galvanizing of the iron must suffer sooner than of yore.

The Americans, with the wooden pins, will escape the currents

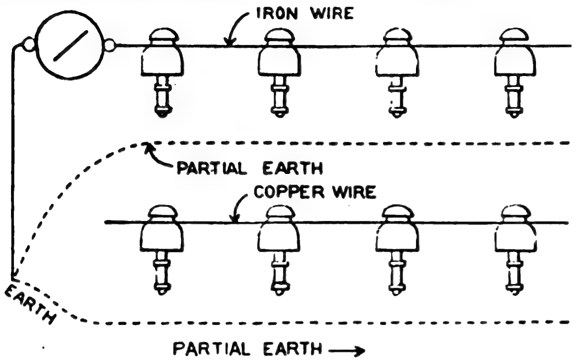

FIG. 5.

due to the difference of metal between the wire and its supports; but when they mix wires of different metals on the same poles the resulting action will be stronger than with us, since they do not earth-wire their posts.

Telephonically, the existence of these currents is of little moment. With metallic loops when both wires are of the same metal, they will not matter at all, since the currents from two similar wires will be in the same direction and of the same strength, and, meeting in the telephone or translator, will neutralize one another.

On single wires, so long as the currents remain steady, their presence does not matter much. As they increase gradually as the insulators become wet, and die away slowly as they dry, they

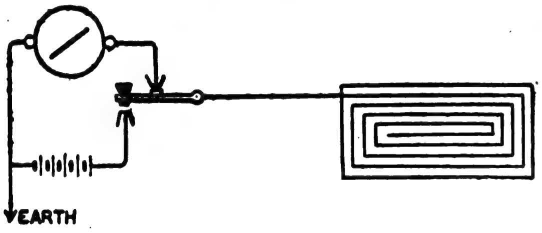

FIG. 6.

do not give rise to any disturbance in the telephone. If any confirmation of the voltaic origin of these currents were needed, it would be afforded in the fact that it is possible by changing the line from a battery, to polarize the line couple even to the extent of obtaining temporary currents of the opposite sign. Thus, the copper was repeatedly charged from a 90-volt battery; when from the positive pole the line current was increased, when from the negative the line current was decreased and sometimes reversed.

The following are particulars of several tests of the copper wire, the deflections being in degrees:—

Charging wire from 90 volts, etc., to line so as to neutralize and overcome line current.

Line current.	Duration of charge.	Result.
.5 +	10 seconds.	Reversed to .2 —
.6 +	20 seconds.	Reduced to 5 +
8.4 +	4 minutes.	Reduced to 3.5 +
12.5 +	10 seconds.	Reversed to .2 —
	Spot went back instantly to 5 +, and then recovered slowly to 12.5 +	
12.5 +	20 seconds.	Reversed to .4 —
	Went back quickly at first, and then slowly recovered to 12.5 + in 45 seconds.	
12.5 +	1 minute.	Reversed to .8 —
	Went back instantly to 3.5 +, recovering slowly to 12.5 in 70 seconds.	
12.5 +	2 minutes.	Same as 1 minute.
12.5 +	3 minutes.	Same as 1 minute.

The same effects were produced with the experimental arm. With only one insulator, reversed, the cup being full of water and the surface well wetted, a deflection was got of 4 degrees, equal to .0027 milliamperes. When the current from this insulator was reduced to .2 + through the surface drying, a reversal could always be obtained to .4 —, and sometimes to .6 —, by charging it from 90 volts —.

During the capacity tests already mentioned, it was observed that for some time after the commencement of rain, the apparent capacity of the wire invariably rose, instead of falling with the decrease of insulation. This effect has, of course, been noticed before, but, as the author was not aware that it had been satisfactorily accounted for, it was resolved to investigate, and the result of the investigation seems to point to several contributory causes. Firstly, no doubt, the line current due to the voltaic action already

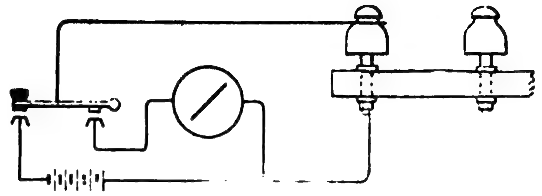

FIG. 7 A.

described will increase or diminish the discharge according to the direction of the charging current. Secondly, the polarization of the bolts due to the charging current will have the same tendency. But the capacity of the line will appear too high when the moisture on the insulators is too slight to permit a voltaic action. To seek the cause of this, 12 feet of copper wire was run on six dry insulators fixed in oaken arms in the test room. With 90 volts the wire gave a discharge of .4 degree. The tops of the insulators around the binding wire were wiped with a wet sponge. The discharge then rose to 1 degree, more than double. Wetting more of the surface of the insulators resulted in a still further increase. Several discharges could be got without renewing the battery charge. It would, therefore, appear that wetting the insulators

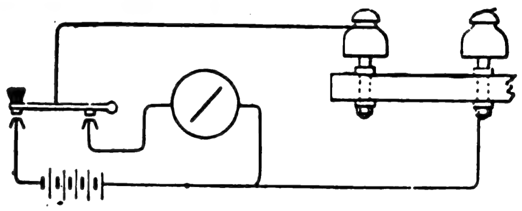

FIG. 7 B.

is equivalent to an increase of conductor surface. The moisture has to be charged as well as the wire, and the consequent discharge is greater than with a dry wire. The effect is only observable in moderate rain, or for some little time after the commencement of heavy rain; when the insulators become thoroughly wet the insulation and the capacity fall together, and then the voltaic action and polarization come into play together with another phenomenon which has not yet been referred to.

Incidentally, in the course of these tests, it was found that when

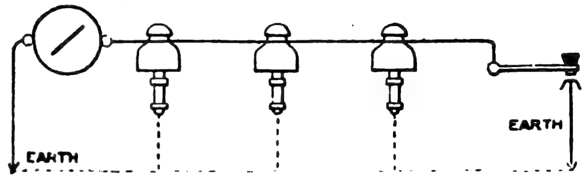

FIG. 8.

a wire is in contact with moist wood, and is charged from a powerful battery (90 volts were used), the discharge is several times stronger than when the same wire is supported on dry or partially moist insulators. Thus a length of wire on insulators gave a discharge of .9 degree; when fastened along an oaken arm not sensibly damp, with staples of the same metal as the wire, the discharge, after 20 seconds charge, amounted to 4.5 degrees, and after 80 seconds to 5 degrees. Then a residual charge appeared to remain in the wood, as the wire continued to yield a current of .5 degree for some minutes, then gradually dying away to nothing. Many tests, varied in details, gave the same results; 30 feet of wire in air gave a discharge of .4 degree. When the same wire was stapled on a deal board (Fig. 6) not sensibly damp, the discharge became 3.5 degrees, falling immediately to 1 degree, and then slowly to zero. The wire and the wood were then sponged and the discharge rose to 7 degrees, falling immediately to 2 degrees, and returning slowly to zero. The wire yielded a series of smaller discharges for several minutes without any fresh contact with the battery. A deal box wetted, having some bronze

wire in contact with it, was well insulated by being suspended by G. P. Charged for 20 seconds from 90 volts, it gave a discharge of 1.6 degrees, sinking immediately to .8 degree, and then gradually to zero. The same box standing on the floor, gave a discharge, under the same conditions, of 12 degrees, sinking to 3 degrees, and then slowly to zero. The same box touched by the end of an earth wire—also of bronze—well away from the bronze wire, gave a discharge of 45 degrees, sinking immediately to 26 degrees, and thereafter slowly to zero. In the two first cases only one metallic conductor, that is to say, the bronze, through which the charge was communicated, was present, and the source of the return current is not very apparent.

The last case closely resembles a wet telegraph pole, the earth wire of which does not touch the bolts. Then an expanse of wet wood intervenes between the bolts and the earth, and a powerful charging current in the line must, with leaky insulators, result in back currents. As it is evident that moisture in wood has the effect of increasing the capacity, it may not be unreasonable to deduce that moisture in the air surrounding the wire may have the same effect.

The foregoing particulars apply whether the line is of copper or of iron; the following observation applies to iron alone.

It has been mentioned that no current between a galvanized iron wire on a wet insulator and the bolt could be detected. But if such a wire is charged by 90 volts, the discharge is followed by a counter current from the insulator. The effect can be produced with a few inches of galvanized iron wire and a wet insulator, as in Fig. 7 A. Charging such an arrangement by 90 volts yielded a discharge of .4 degree and a counter current of .3 degree, which did not wholly disappear for some three minutes. Obviously, the polarization of the bolt following on electrolysis of the moisture made the insulator a secondary battery. The effect of damp wood may be markedly shown by shifting the return wire to the bolt of an adjoining insulator, as in Fig. 7 B. The discharge then became 1.5 degrees, and the counter current 1 degree, an augmentation of nearly four times.

Connecting the earth wire direct to the bolts will obviate the effect of moist wood, but it increases the strength of the voltaic action and the polarization of bolts by the charging current.

Although the Americans escape the voltaic action consequent on the use of metallic bolts, the damp wood of their poles cannot be without its effect in wet weather with the insulators they use.

The current set up between copper wire and iron bolts in wet weather might be used to signal with. The experiment has not been tried, but it seems plain that a galvanometer at A, Fig. 8,[2] through which the line current circulates in its full strength when the wire is insulated would be affected, for the key when closed would shunt a large proportion of the current around the galvanometer.

It will be observed that these experiments were made with the distant ends insulated, a condition which does not obtain in ordinary telegraphy. The practical effect of the disturbances may be insignificant, especially with double current working but still it is well to know that they exist.
